Throughout the portion of this article which gives details of the various processes, it will have been observed that constant stress is laid upon the reactive power of the body, as it is exercised upon the application of these processes. Upon this power is based the whole rationale of the treatment in question. It was mentioned under the 'History of Hydrotherapeia,' that Priessnitz had intuitively concluded that when disease was abolished it was by the efforts of the body itself, and not directly by the remedy employed, and that therefore 'strength' was requisite. So long as the organism exists in life, there is always more or less of this organic strength upon which Priessnitz built; and one of the most necessary, and at the same time the most nice calculations which medical art has to make, is the quantity of the power referred to which still remains in the body after all the ravages of acute or chronic disease; for upon this calculation must be based the quality and amount of the treatment to be employed. What is called diseased action is itself a reaction of the organic strength upon some offending cause, such as cold, heat, bad food, poisons, fatigue, violence, &c. The first reactive exhibition thus made is, in the majority of cases, a vehement one, involving excessive action of the nervous and circulatory functions. This immediate and violent reaction, which is for the purpose of throwing off and remedying the results of the morbid cause, is the phase of disease commonly called 'acute.' Excessive rapidity of the nervous and circulatory functions is its attribute; all is tumult and disorder. If by any means this rapidity and tumult can be subdued, and the body thereupon relieves itself by eruption or excretion of some kind or other, there is an end of the disease. But if, whilst the dangerous tumult of the functions is subdued, the body does not relieve itself by eruption or excretion, more or fewer organs fall from the excessive activity which they exhibited into a state of exhaustion of organic power—an exhaustion having a proportion with the amount of the previous excitement in which they were. This condition and phase of disease is what is called 'chronic.' Both states may be thus illustrated: in consequence of a chill, acute inflammation of the lungs ensues, characterized, as every one knows, by very rapid pulse, very rapid breathing, very hot skin, difficult expectoration, &c. Remedies subdue the pulse, breathing, and heat of skin, but are not followed by either a collection of matter in the tissue of the lung, nor by copious secretion from the inflamed parts into the air tubes; the immediately dangerous part of the inflammation is past, but the tissue of the lung remains surcharged, oppressed with an undue quantity of blood, the continued presence of which constitutes the 'chronic' disease of the organ. The intensity and duration of the acute stage varies in individuals. In persons whose original congenital supply of organic power is small—in other words, in persons of feeble constitution—the acute stage is feeble and brief, and speedily passes into the chronic stage, or else extinguishes the individual. In the

former case the acute stage often passes unobserved, and the statement is that 'the disease came gradually on;' in the latter case the organism sinks under the effort to relieve itself from an offending cause. To take up the illustration of the diseased lung again: the chronic stagnation of blood in the tissue of the lung being established, it becomes a source of sensitiveness and irritation to other organs and to its own tissue; the heart is readily excited; the windpipe and organ of voice are rendered exquisitely sensitive to cold air; the nerves of respiration are played upon, and cough induced; the very skin is rendered more delicate; whilst the mass of blood congregated in the tissue of the lung is irritating the organic sense of that tissue, and constantly tending to set up a new, chronic, disintegrating inflammation therein—an inflammation in which the organic power is so diminished that it is altogether unable to make efforts to relieve the distressed function of the organ.

Now, in both the instances of acute and of chronic disease, the thing to be dealt with is the organic power of the organ involved. In the acute state of disease this may be more readily measured; it is in violent reaction against a peccant cause, and the aim of the practitioner is, plainly enough, to restrain the excess of activity, so that life shall not be extinguished by its subsequent complete exhaustion, and to direct such activity from the important organ involved to some less important organ. Accordingly, the hydrotherapeutic applications to this form of disease are all of the soothing and subduing kind, such as diminish the pulse, soothe the cerebral and nervous tumult, and cool the fevered skin. All this moderates the vehement efforts of nature, and directs the irritation of which she is striving to rid herself towards the skin, upon which the remedies are applied; and, as has been said in speaking of the packing, this may be done so perseveringly as to exhaust the internal fever and irritation entirely by the skin; so that, in the case of inflamed lung before alluded to, the inflammation shall cease without either the prolonged and copious expectoration which so often attends its solution, or the lapse into the chronic form. The limit to this subduing and soothing process must be looked for by the practitioner in the collapse of the pulse and of the nervous power; for the organic power of individuals varies infinitely. If, after employing subduing measures against an acute internal disease for a certain time, the diseased condition still continues, but the action of the heart has been so lowered, and the excitement of the nerves so subdued, as to cause fluttering of the heart, with tremor and faintness of the nerves, then there is reason to fear that the patient is about to succumb to the internal malady, persisting as that does in spite of the remedies in question: his organic strength can no longer react upon them, and therefore is unable to throw off the diseased state which first roused all the tumult. If, on the other hand, the internal acute malady diminishes *pari passu* with the diminution of the nervous and circulatory tumult induced by it, the organic power of the patient must still be carefully measured by the practitioner, and must not be permitted to sink so low in its reactive energy as to be unable eventually to rid the body of the primary malady; for in the contrary case, that

malady would become a chronic one, liable to take on acute activity on provocation, and causing the formation of all kinds of morbid sympathies of the diseased organ with other organs, and perhaps the destruction of its own tissue.

In acute disease, therefore, it will be seen that the success of treatment by hydrotherapeutic means depends upon the skilful measurement of the organic power which the patient possesses, both to react upon those means and to recover the body from the original malady. It should ever be remembered that hydrotherapeia depends for its success upon the curative reaction of the disordered body itself, and makes no pretension to the possession of antidotes which are presumed to drive out disease, either because they are of a contrary nature to that disease, as is the case with allopathy; or because they are of the like nature in their pathogenesis, as is the case with homeopathy. Upon this fact is fairly based the assertion that treatment by hydrotherapeutic means involves more accurate appreciation of the physiological state of the body, and more minute skill in the choice of remedies which shall arouse its curative reaction without exhausting it, than are required or than could be possibly applied in the ordinary systems of antidotal medication.

But if the measurement of the powers of the body be a matter of nicety in the midst of the excessive activity of acute disease, it requires still more appreciation of these powers when that form has lapsed into the chronic state. For in chronic disease there are two opposite phases of vitality to be dealt with. The bloodvessels of the chronically diseased organ, after having their vital contractile power strongly excited during the acute stage, fall into the opposite condition of exhaustion and relaxation. In this condition they occupy more space and contain more blood than they should healthily do, and on both these accounts are a source of irritation to the nervous tissue both of their own substance and to that of immediate and distant organs. Here, then, are two opposing conditions, demanding opposite treatments: relaxed and enfeebled bloodvessels, and irritable nerves caused by them. This is the double condition which meets every close observer of chronic disease. It may be illustrated by the case of an acutely inflamed liver which has fallen into a state of chronic congestion; its bloodvessels, weak and gorged, irritate the nerves which run in the tissue of the liver itself, and, not only so, are a source of irritation to distant organs, as is evidenced by the headache, throbbing and heaviness of the brain, by the obscuration of the sight, by the irritable state of the throat, the foulness of the tongue, the disordered urine, the constipation, the dry, harsh skin, &c. Now, in treating such a case hydrotherapeutically, the soothing portion of the remedial applications would tend to increase the congestive feelbleness of the bloodvessels of the liver, whilst the stimulating measures, which would rouse these vessels to efforts to rid themselves of the oppressive blood with which they are charged, would tend to maintain and augment the nervous irritation of the liver itself and of the various organs with which it morbidly sympathizes. The longer the chronic state of disease has existed, the more decided are both these conditions; the feelbleness and congestion of the diseased organ

becomes more decided, and its nervous sensitiveness and sympathies more intense and more extended.

In treating chronic disease by the hydrotherapeutic method, therefore, one of these two opposite conditions must first be dealt with. The nervous irritation of the organ itself, and of its sympathizing organs, is obviously the first that demands attention, because it is that which gives the greatest amount of suffering to the patient, and because it is the most recently established condition. Accordingly, the practitioner, having accurately measured the extent and intensity of that condition, will proceed to apply soothing and subduing processes with fitting caution. For the most part there is, besides the inherent irritation of the original malady, an immense accumulation of nervous irritation all over the body, produced by the long-continued employment of futile tonics, sedatives, aperients, &c., all administered in the vain attempt to remove a causal disease by palliating its morbid sensational and secretorial effects. And besides these positive irritants, there is the negative result of neglect of the most sensitive of all the bodily surfaces, the skin; rarely, if ever, has any attempt been made, in the long course of the ordinary medications, to bring into play the vast and acute sympathies of that surface for the purposes of acting upon interior organs or carrying off irritation from them. Like all organs, therefore, whose functions have been neglected and whose vitality has been called away to be concentrated on other organs, the skin is mostly found, when chronic cases are first submitted to hydrotherapeutic treatment, to be in a state of exquisite sensitiveness and of obscured reactivity; it has been ignorant of the touch of water, and is therefore intolerant of the touch of air, from which it has been for years excluded under masses of flannel and other supposed armours from evil. With the brain and spinal cord rendered irritable by the internal chronic malady; with the heart, kidneys, and womb rendered irritable by their direct nervous connections with the primary diseased organ, and indirectly so connected through the brain and spinal cord; with the skin painfully alive to external impressions, but nearly dead as to the power of reaction on these impressions—it is no wonder that, when the first soothing hydrotherapeutic measures are applied to the body through the skin, the result should be that of great relief to morbid sensation and suffering, and a resilient feeling of health to which the patient had been a stranger for months or years. And such is the fact, in a very short time, in the great majority of cases: it is a common thing for patients, after treatment for a week or two, to declare themselves better than they had been for many months, and even to declare themselves well. But these sensations are only the result of the reduction of the sympathetic nervous irritations already referred to; through the exquisitely sensitive skin, the nerves of which take their origin in the spinal cord, a soothing effect is produced upon the interior nerves proceeding from the same source, and between the renewed secreting activity of the skin and the diminished excitement of the internal nerves, the sense of improved well-being is readily explained.

But this more or less extended nervous irritation is not the disease to be cured; it is only, as it were,

the unhealthy atmosphere thrown out by the focus of disease in the specially diseased organ. In that organ is found that prostration of circulating power which constitutes the chronic state, and which must be overcome before it can cease to be a source of mischievous function to other organs. To the attack upon this centre of diminished organic power must now be brought all the agencies of hydrotherapeia whose office it is to rouse dormant bloodvessels—the stimulating processes of that mode of treatment. If the patient from long disease has become bloodless as well as nerveless, it will be necessary to employ the hot processes of the lamp sweat, vapour bath, general hot bath, &c., so as to draw blood to the exterior without the necessity for reactive exertion on the part of the body. And whilst the skin is thus artificially filled with blood and excited in its nervous power by applied heat, that power should be called into play by subsequent frictions or ablutions more or less low in temperature, and always lower than that of the skin. By the frequent repetition of this method, the bloodvessels of the skin gradually become the receptacles of more and more blood, and gradually acquire the power of reacting more and more upon the external temperature, which temperature should be steadily lowered with the increasing ability of the skin to bear it, and to react upon it. After a time the power increases so much as to permit the application of measures which call forth the reactive energy alone without the attractive power of heat; and pail douches, rose douches, falling douches, and other cold stimulants, are introduced for the purpose of arousing the tumult of the interior organs which is to rid them of their oppressed and torpid state of circulation. When the body is able to bear these, the sweating process is applied only from time to time to aid, by varying means, the advent of the revolution which it is desirable to cause in the vital actions. It is well to bear this in mind: variety of mode of stimulation adds much to the amount of stimulation. In many cases this variation requires to be regulated by the weather; when cold dry winds prevail, the lamp sweat should be most used; in warm, moist weather, the cold stimulants. In many other cases the disease regulates the employment of either kind; generally speaking, chronic disorders of the abdominal organs require only a small admixture of hot stimulation; whilst in affections of the chest and of the exterior organs, as in gout, rheumatism, and skin diseases, the lamp and vapour baths should be largely applied, but still with cold stimulation added. The stimulation is thus affected, and the resulting tumult is further augmented by the drinking of large quantities of cold water and a good amount of bodily exercise, especially in affections of the liver and kidneys, in gout and rheumatism, in states consequent on courses of mercury, iodine, and other poisonous minerals where, as in gout and rheumatism, the blood requires to be purged and changed as well as regulated in its circulation.

It has happened that the patient generally expresses a sense of rapid improvement whilst under the preliminary soothing treatment. On the other hand, it constantly happens that when the stimulating treatment has been in progress for a while, the patient begins to complain that he does not feel

so well, that the treatment appears to be disagreeing, &c. This is the expression of the tumult which the treatment is causing in the chronically affected organs, a tumult which is spreading sympathetically to the great nervous centres, causing therein malaise, sleeplessness, nervousness, faintness, &c., and radiating thence to cause palpitations of the heart, short breathing, nausea, &c. When more or fewer of these symptoms prevail, it is well to intermit some of the stimulating processes and to substitute some of the soothing, packing in towels or sheet, for instance, alternately with the lamp or douche; or ceasing the latter altogether for a while, if the above-named symptoms of disturbance continue notwithstanding the intervention of the soothing measures.

In this manner the hydrotherapeutic treatment is applied perseveringly to undermine and subvert the long-standing morbid action of more or fewer organs. The object is to revolutionize, to subvert altogether. It may be necessary to delay this conclusion from time to time in order to spare the nervous power, and prevent grave nervous effects; but that object must be kept steadily in view: the disease is not cured until a total change in the affected organs, and frequently also in the character of the blood of the whole body, is made. Sometimes the gradual alteration of the sensations, secretions, and mental and locomotive powers gives evidence of this, without the sudden and violent explosion of some secreting organ, such as the liver, stomach, bowels, kidneys, or skin, or the throwing out of some eruption of a diffused, or itching, or burning, or furuncular kind. But at other times some of these exhibitions of tumultuous effort on the part of the body take place, and vomiting, diarrhoea, copious and loaded urine, sweatings, various eruptions of the skin or large boils upon it, then afford evidence of a *crisis*, as it has been called. This critical action may come again and again; the intervals being the periods during which the nervous system is resting from its past, and accumulating power for its future efforts in the same direction. Whilst such efforts are actually going on and the *crisis* is present, it is not well to interfere with it by continuing the stimulating treatment; it is best, in fact, to intermit all treatment save such as will keep the skin in active function; for the effort is a natural one, and nature is doing all that it is desired should be done, namely, throwing chronic irritation which had long possessed important organs upon other organs wherein it cannot involve life, and whence it is evolved by secretion. But it is expedient to renew the perturbing treatment immediately on the cessation of the critical action; and if it fails to cause renewal of such action, and if, on the other hand, it only irritates the nervous centres, as will be shown by sleeplessness, excitement of mind, diminished locomotive power, &c., then it may be concluded that no further irritation remains to be expelled, and the treatment may be speedily terminated.

The tumult through which the patient passes in the process of cure causes in him an incapability of appreciating the benefit which the treatment is effecting on him. At first, as has been said, the subduing of sympathetic irritations induces sensations of relief and health; then comes the perturbing treatment which stirs up the old morbid arrange-

ments, and during which the patient often suffers much uneasiness; and it is not until all the tumult produced by the treatment has subsided that he really feels how much he has gained by the ordeal through which he has passed. In some instances this sensation of totally restored health is not experienced until the end of two, three, or even four months, so deeply were the roots of disease planted in the organs, so violent and prolonged the tumultuous effort which was necessary for their eradication.

From all that has preceded it will be seen that the water treatment differs from other methods in this, that it calls upon the powers of the body to effect the restoration of the organs, which is not the pretence of either the allopathic or the homœopathic modes of treatment. Further, it will be seen that it aims at *cure* and not at *palliation*, as is the fact with regard to allopathy. For both these reasons, it is apparently more tedious in its career and less brilliant in its immediate operations. But even in this particular, an exception must be taken in the instance of acute disease, in which the speedy results are frequently marvellous. In high states of fever, for instance, a single pack in a sheet will often reduce the pulse by fifteen or twenty beats in the minute, and induce sleep quite as directly as the most approved narcotic drug. And in cases of profuse diarrhoea or menstruation, the application of a very cold sitz bath for five or eight minutes will constantly have the speedy effect of arresting the discharge. The same rapid action applies to the effect of a long sitz upon a headache, or of a foot bath upon a toothache.

It must not be supposed, however, that the advocates of hydrotherapeia repudiate altogether the employment of medicinal agents. Several of the most distinguished practitioners of that treatment in Britain mingle homœopathic treatment with their own, more especially Dr. Gully. And among the allopathic remedies they do not utterly discard narcotics and diffusible stimulants, when either overwhelming pain or alarming faintness threatens to extinguish vitality. On the other hand, it is now certain that hydrotherapeia is gradually finding its way into the ordinary style of healing and becoming part of it. In the Edinburgh Infirmary, at St. Thomas', and other hospitals of London, the treatment of febrile complaints by packing in towels and sheets is becoming general, whilst in private practice the employment of compresses and of sitz baths is extending almost every month. It is to be hoped that this candid examination and utilization of all that may aid the patient to obtain palliation of suffering or recover health will continue to increase, and the narrowness of sectarian views, which tells against the patient and only in favour of sectarian passions, to expand, so that medical art, so short-coming in the combat with the multifarious assaults of disease, may receive into her armoury of remedies the extensive and powerful agencies of hydrotherapeia.

HYDROPHILIDÆ, a family of coleopterous insects established by Leach. The insects of this family are included by Latreille in his section *Palpicornes*. They have generally nine joints to the antennæ, but sometimes only six; the terminal joints always form a perfoliated knob; the maxillary

palpi are very long and slender; the body is usually oval or rounded, convex above and flat beneath, or nearly so: the tarsi are five-jointed, and the mandibles bidentate.

The principal genera are *Hydrois*, *Hydrophilus*, *Spercheus*, *Berosus*, and *Hydrobios*.

HYDROPHOBIA (from *ὕδωρ*, 'water,' and *φόβος*, 'fear') is the disease occasioned by inoculation with the saliva of a rabid animal, and is so called from the violent and suffocating spasms of the throat which occur when the patient attempts to drink, or when, in the latter stages, the mere idea of drinking arises in his mind. The exciting cause of this disease is the poison of rabies, which is generated in the dog and various animals of the canine species, such as the wolf, fox, and jackal; and which may by them be communicated to other animals, such as cats, horses, pigs, and also to man.

The disease may be communicated to man either by the saliva being carried into a wound made by the tooth of a rabid animal, or by its being placed on the surface of a previous wound, as where dogs have licked the hand or face of a person in which there was any raw surface. If a mad animal bite through the clothes, there is great probability that all the saliva will be wiped off from its teeth as they pass; and hence wounds of the hands and face are generally the most dangerous. The poison is of a fixed and not of a volatile character, and capable of being propagated as long as the corpse has not become perfectly rigid.

The period after the inoculation at which the symptoms of hydrophobia may exhibit themselves varies greatly. In general the disease appears between the thirtieth and fortieth day from the injury; but cases are known where it has been delayed for several months. The bite of a rabid animal generally heals up like that of a healthy one, and the patient is attacked when he had forgotten that he was ever bitten. In some cases, however, before hydrophobic symptoms appear, the scar of the wound becomes painful, red, and swollen, and pain is felt shooting from it along the course of the nerves of the part, as if it were going to ulcerate. The first decided indication of the disease is that the patient has headache and general uneasiness; he loses his appetite, and when he is about to drink he suddenly feels an aversion to any liquid, and finds a difficulty in any attempt to swallow it. The symptoms rapidly increase in severity: any attempt to drink, and even anything that can suggest the idea of drinking, is sufficient to bring on the most frightful spasms of the throat, threatening instant suffocation, and producing the most severe pain. The convulsions, which were at first limited to the muscles of the throat and of deglutition, after a short time extend to other parts of the body. As the disease proceeds, the convulsions of the throat become more frequent and severe: the slightest noise or vibration of the room is sufficient to excite them; there are severe headache, a rapid pulse, a foul tongue, and other symptoms of a generally disordered condition of the system. A copious secretion of thick tenacious mucus clogs up the air passages, and it is in his attempts to free himself from this that the patient coughs and makes a loud harsh noise, which has been supposed to resemble the barking of a dog. Sometimes there is furious

delirium, but often for the last few hours of life the patient becomes quiet; he then rouses from his tranquillity, and, after one or two comparatively slight convulsions, expires. The duration of the disease is very rarely more than six days, and it often terminates fatally in twenty-four hours.

No method of cure has yet been devised for this terrible disease, and the only question that can be satisfactorily considered is that of prevention, which can only be accomplished by the removal of the morbid saliva from the wound before it has had time to produce its fatal influence on the body. The surface of the wound should be well washed, and then the whole area of it excised, and caustic applied to every part of the cut surface. Water dressing should then be used. It may happen, however, that the wound is so lacerated, or penetrates into such structures, that the complete separation of it by the knife is impossible. If it occurs in a finger, for example, it may be amputated; but if a more important member is implicated, the circumstances should be submitted to the patient. If he prefer running the risk and retaining his limb, the wound should be thoroughly washed and cupping-glasses applied over it, or a potent caustic may be used.

HYDROPHYLLACEÆ, a natural order of exogenous plants. It is near *Boraginaceæ*, but differs in the structure of its seeds and fruit. Many of the species, especially those of the genera *Nemophila* and *Eutoca*, are beautiful objects: they are all natives of North America.

HYDROPS PERICARDII, or *Hydropericardium* (from *ὕδωρ*, 'water,' and *περικαρδιον*, the 'pericardium'), is a collection of an unnatural quantity of fluid in the sac containing the heart.

HYDROSTATIC BED. [BEDSTEAD.]

HYDROSTATICS is the science which relates to the pressure and equilibrium of the fluids commonly called non-elastic, or incompressible; as water, mercury, &c., and to the equilibrium of bodies immersed in them. The elastic fluids, as air, steam, &c., are the subjects of Pneumatics.

The cause of fluidity in bodies has been the subject of much discussion; it has been supposed to depend on the globular form of the particles, on the caloric contained between them, or on both these circumstances combined. But whatever may be the primary cause, it is admitted by all that the property must arise immediately from the perfect mobility of the particles among one another. Differences, however, exist in the fluidity of different bodies, such as mercury, water, &c., which in their ordinary state possess this property in a high degree; while the particles of many fluids, as the oils, have a sensible adhesion to one another. Except pure alcohol, all the non-elastic fluids at certain temperatures congeal, and lose their fluidity.

Since the particles of all bodies, fluid as well as solid, are separated by intermolecular spaces, it may readily be conceived that no fluids can be absolutely incompressible; and experiments have proved that spirit of wine, oil, water, and even mercury, can, by pressure, be reduced in volume in certain degrees; the fluids which have the greatest specific gravity suffering the least compression. But as this diminution is very small when compared with the volume of the fluid (being for water, only $46\frac{1}{10}$ millionths

of its bulk with a pressure of 15 lbs. on the square inch), for all practical hydrostatic purposes such fluids may safely be considered as experiencing no change of volume by the compressions to which they may be subjected.

Experiment has also shown that *all the non-elastic fluids possess the property of transmitting equally in every direction the pressure exerted against any point on their surface*. This property is the fundamental principle of hydrostatics, and most of its other propositions are only different forms or direct consequences of this truth. If, for example, a piston were forced into an orifice made in any part of the side of a vessel containing such a fluid, the effect of the pressure would be experienced equally at every point on the whole surface of the vessel; but the pressure thus exerted must be distinguished from that which is caused by the gravity of the fluid, the former being the same in every part of the fluid mass, while the latter, at every point in the sides, depends on the depth of the point below the upper surface of the fluid.

If a fluid at rest in a vessel be supposed to consist of an infinite number of filaments, or infinitely slender columns in vertical positions, the pressure, which, in consequence of the weight of the particles vertically above, is exerted in every direction by any particle of one filament, will be counteracted by the equal pressure of all the surrounding particles, so that the filament will remain at rest, and act by its gravity on the particle vertically under it. Also, the pressure exerted by the fluid against every part of the surface at the sides or bottom of the vessel containing it, will, while the fluid is at rest, be perpendicular to the surface; since otherwise the reaction of the surface could not entirely destroy that pressure, and a part of it would disturb that equilibrium which, by hypothesis, is the condition of the fluid in the vessel. The amount of that reaction is, of course, equal to

the weight of any one of the vertical filaments comprehended between the upper surface of the fluid and a horizontal plane passing through the elementary surface pressed. The pressure of all the particles in the upper surface of the fluid is evidently null.

It may hence also be proved, that the pressure on the base of any vessel containing a fluid will be the same, whatever be the form or position of the sides of the vessel, provided the fluid always reaches the

same height above the base. For, let $ABCD$ be a vertical section through a prismatical vessel; the pressure on any point, a , of the base is evidently equal to the weight of the vertical filament, ba ; that on any point, c , of the inclined side, BD , is the weight of the filament, cd ; and this last produces no effect on the base, because the lateral pressures of all the particles in every vertical filament are counteracted by those of the particles in the neighbouring filaments. The same thing must be understood of all the water in the portion EBD . The pressure on any point, e , under the inclined side, AC , is equal to the weight of the filament, ef , together with the pressure arising from the reaction of the side, AC , at f , in the vertical direction, fe ; and this reaction is, from what has been said, equal to the weight of a filament which may be supposed to exist above f , with a height equal to fg . Consequently, the pressure on AB , when the sides of the vessel are inclined to the horizon, will be equal to that upon the same base when the sides are in vertical positions. This is the foundation of a popular experiment, when columns of water of equal height, in cylindrical and conical vessels, having equal bases, but, of course, containing very different quantities of the fluid, are shown to be in equilibrio with one and the same weight applied to prevent the movable bases from descending.

It may readily be inferred from these statements that the pressure on the base will be equal to the weight of a vertical prism or cylinder of the fluid, whose base is that of the vessel, and whose altitude is that of the fluid which it contains, whatever be the form or inclination of the sides.

On the same principle may be explained the hydro-

statical paradox. In this experiment is employed a cylindrical machine formed of two circular plates of wood, as AB and CD , with sides of leather like those of a pair of bellows. A tube, FE , is inserted in an orifice near the bottom, and through this tube water is poured into the cylinder, till the boards, AB and CD , are at any distance asunder within the limits allowed by the leathern sides. Then if any weight be placed on the board, CD , it will cause the water to rise in the tube, EF , to a certain height, suppose a ; and the weight of the small column, ab , of water may be considered as holding in equilibrio the weight imposed on CD ; which will, in fact, be found to equal that

of a cylinder of water whose base is the area of the board CD, and whose height is equal to ab .

If the tube, EF, were made to decline from the vertical so as to take any oblique position, EF', it would follow, since the pressure of a fluid by gravity depends on the vertical height only of the column, that the fluid in the tube, from the same pressure on CD, would rise till its upper surface is in a horizontal plane, aa' , passing through a : and the weight of the column of fluid must be estimated by the area of the horizontal section at b' , multiplied by the vertical height of a' above b' .

The pressure exerted by a fluid against the side of a vessel containing it, or against a surface immersed in it, whether that side or surface be plane or curved, is, by the theory of parallel forces, equal to the weight of a column of the fluid having the surface pressed for a base, and to the distance of the upper surface of the fluid from the centre of gravity of the former surface for its altitude. By this theorem the pressure of water against the walls of reservoirs, lock-gates, &c., may be determined, and the relation ascertained between the weights of the fluid in vessels of various forms and the pressures against the sides.

The centre of pressure in any surface subject, like the side of a vessel containing a fluid, to the hydrostatical pressure of the fluid, is that point at which, a force being applied in a direction contrary to that of the pressure, the surface will be kept in equilibrio; and in all cases, when the surface pressed is symmetrical on each side of a line joining the centres of gravity and pressure, the latter coincides with the centre of percussion in mechanics.

When a triangle in a vertical position is pressed by a fluid, its vertex coinciding with the upper surface of the latter, and its base being horizontal, the distance of the centre of pressure from the vertex is equal to three-fourths of the perpendicular of the triangle. And when a circle in a vertical position is so pressed, its upper part just touching the surface, the distance of the centre of pressure from that part is equal to five-eighths of the diameter.

The equality of the pressures in every direction at any point in a fluid mass, is the cause why, if a solid body be immersed in a fluid, the pressure of the fluid immediately under it will tend to raise the body upwards with a force equal to the weight of the fluid it displaces. But the weight of the body is a force acting vertically from above downwards, and, consequently, in an opposite direction to that of the reaction of the fluid. Since, therefore, the volumes of the body and of the displaced fluid are equal to one another, if their weights or densities should be equal, the body would remain in equilibrio in whatever situation it were placed in the fluid. But should these weights or densities be unequal, the body would make an effort to ascend or descend, according as its density is less or greater than that of the fluid; and in order to counteract these tendencies, it would be necessary to use a force equal to the difference between the weight of the body and of the displaced fluid. Hence, if a solid body be weighed in a fluid, it will be found that its weight, compared with that of the same body in vacuo, will be less than in the latter case by the weight of an equal volume of the fluid; and, consequently, when

a body is weighed in a fluid, as water or air, the true weight, or that which would be obtained in vacuo, will be found by adding to the observed weight that of an equal volume of the fluid.

When a body floats in a fluid, in order to bring its upper surface to coincide with that of the fluid, it must evidently be loaded with a weight equal to the difference between the weight of the body, or of the displaced fluid, and the weight of a volume of the fluid equal to that of the whole body. The weight which a floating body will thus bear is denominated the buoyancy of the body; and on the principle here stated depend the common rules for finding the buoyancy of rafts, vessels, &c.

If a solid body float in equilibrio in a fluid, the centres of gravity of the body and of the displaced fluid must evidently be in one vertical line; otherwise the upward action of the fluid below, which necessarily has its resultant in a vertical line passing through the centre of gravity of the place occupied by the body, would produce in the latter a rotatory motion contrary to the hypothesis. This circumstance has given rise to three distinctions in reference to the equilibrium of floating bodies. If the centre of gravity of the body should be below that of the displaced fluid, the body is said to possess a stable or firm equilibrium; if above, the body is said to float with a tottering equilibrium; and if the said centres should exactly coincide, the body would float in any position whatever, and is denominated an equilibrium of indifference.

The absolute weight of a given volume of any solid or fluid body is called its specific gravity. In this country, for convenience, it is customary to consider one cubic foot as the given volume, and to express the weight in avoirdupois ounces: thus the weight of a cubic foot of rain-water being 1000 ounces, and that of a cubic foot of cast iron being 7207 ounces, those numbers are used to denote the specific gravities of the bodies. From this definition it follows that, when the volumes of two bodies are equal, their specific gravities will be proportional to their weights: when the weights are equal, the specific gravities are inversely proportional to the volumes; and, in general, the weights of bodies vary in a ratio compounded of their volumes and specific gravities. [SPECIFIC GRAVITY.]

HYDROTHORAX (from *hydor*, 'water,' and *thorax*, 'the chest'), dropsy of the chest, is a term applied to express the existence of serum in the pleural sac. This morbid collection may take place in consequence of inflammation of the pleura, which, like inflammation of other serous membranes, may terminate in effusion; or it may result from the causes of general dropsy. [DROPSY; PLEURITIS.]

HYDRUS (constellation), the Water-snake, commonly called the Southern Snake, a constellation of Lacaille. It is situated between the south pole and the bright star in Eridanus (Achernar).

HYDRUS, a genus of serpents which have the posterior part of the body and the tail very much compressed and elevated vertically, so as to give them a facility of swimming adapted to their aquatic habits.

Cuvier places them with *Bongarus*, or *Bungarus*; Daudin distinguished them as a tribe of serpents whose jaws are organized and armed nearly as in the

non-venomous serpents, but which have the first of their maxillary teeth larger than the others, and pierced for conducting the poison, as in the venomous serpents with isolated fangs. He subdivides these water-serpents, which are said to be very common in the intertropical regions of Asia, and the neighbouring islands, into the two genera *Hydrophis* and *Pelamides*. Cuvier adds the sub-genus *Chersydrus*.

HYERES, a town in the French department of Var, situated 10 miles E. from Toulon, on the southern slope of a hill that looks over a beautiful plain covered with plantations of the orange, citron, vine, olive, pomegranate, mulberry, and palm, and terminating in the Mediterranean, stands in $43^{\circ} 7' N.$ lat., $6^{\circ} 7' E.$ long., and has 5430 inhabitants. It is considered one of the healthiest winter residences in the south of France, being protected by hills from the north-west winds, and also from the direct influence of the south-west, which sometimes blows with great violence in this part of the Mediterranean. It is much resorted to by persons suffering from chest and nervous complaints. The group called the Iles d'Hyères lie near the coast.

HYGIENE or HYGIENE. That department of medicine which treats of the preservation of health. From Hygeia, the fabled Goddess of health.

HYGINUS, CAIUS JULIUS, a freedman of Augustus Cæsar, and a grammarian, was, according to some, a native of Spain, but according to others, a native of Alexandria. He was placed by Augustus in charge of the library on the Palatine Hill, and also gave instruction to numerous pupils. His numerous works are quoted by the ancients; but they are all lost.

HYGROMETER (*hygros*, 'moist,' and *metron*, 'measure') is an instrument serving to determine the quantity of aqueous vapour in the atmosphere, or other gas under examination. M. De Luc employed for this purpose a thin slip of whalebone, whose contractions indicated the variations of moisture; and De Saussure had recourse to a human hair, by means of which he constructed a far more delicate instrument; which was, however, exceedingly liable to derangement, and, unless prepared with extraordinary care, was uncertain. A very ingenious instrument was also invented by Leslie, but all previous inventions have been superseded by the hygrometer which the late Professor Daniell introduced. It consists of two thin glass balls; one inch and a quarter in diameter, connected by a glass tube about seven inches in length. The tube is bent in two places at right angles, so as to form three arms of unequal length, the longest of which contains a small thermometer, whose bulb descends into the lower of the two glass balls. This ball, after being about two-thirds filled with ether, is placed over a spirit-lamp until the vapour of the ether has expelled the contained air through a capillary tube, which is left open for the purpose, and afterwards hermetically sealed. The other ball is then covered with a piece of muslin, and the instrument thus adjusted is placed upon a stand, to which is attached a small thermometer indicating the temperature of the external air. When about to be used, a small portion of ether is poured upon the muslin, which, by evaporating, lowers the temperature of the glass ball, and thereby

occasions a rapid condensation of the ethereal vapour contained within the instrument. The condensation of the vapour within the tube produces a continuous evaporation from the surface of the ether in the lower ball, whereby the temperature of the included ether is continually reduced, until a deposit of moisture from the surrounding atmosphere is observed to take place upon the exterior of the glass. At this instant the inner thermometer, which always indicates the temperature of the ether, is observed, and thus the dew point, or that at which the precipitation of atmospheric moisture takes place, is determined with considerable accuracy. Having ascertained the dew point, and likewise the temperature of the external air, the actual quantity of moisture contained in the cubic foot of air will readily be found from the formula,

$$\text{Weight in grains} = \frac{5656 \cdot 2}{448 + t} \times p,$$

where t denotes the temperature of the external air, and p the elasticity of aqueous vapour at the temperature indicated by the interior thermometer. The value of p for every degree of the thermometer is given in Mr. Dalton's tables of the expansive force of steam. This instrument, so excellent in theory, is very costly, on account of its great consumption of ether, and can scarcely be used in hot climates, owing to the difficulty experienced in preserving that fluid. It is also objected to because an experiment has necessarily to be made to obtain an observation. It was employed for the determination of the dew point at the Royal Observatory, Greenwich, from 1840 to 1847, but since that period it has been superseded by the more convenient instruments—the wet and dry bulb thermometers. This instrument consists of two thermometers—an ordinary one, to give the temperature of the air; and another, whose bulb is covered with a piece of muslin, or other similar material, to which is attached an absorbent wick, communicating with a vessel of rain-water—an arrangement by which the muslin is kept constantly wet. The evaporation from the muslin, and consequent cooling of the bulb, being in proportion to the dryness of the air, the difference between the readings of the two thermometers will be greatest when the air is driest, and zero when it is completely saturated with moisture. The reduction of the observations to derive the elastic force of vapour at the dew point is effected by the formula of Dr. Apjohn:—

$$(1) F = f - \frac{d}{88} \cdot \frac{h}{30}; \quad (2) F = f - \frac{d}{96} \cdot \frac{h}{30},$$

(1) to be used when the reading of the wet thermometer is above 32° , and (2) when below. In these formulæ, F is the elastic force of vapour at the dew point; d the hygroscopic depression, or depression of the dew point; h the height of the barometer; and f the elastic force of vapour for the temperature shown by the wet thermometer. In these calculations, Mr. Glaisher's 'Hygrometrical Tables' will be found of very great value, as they include all the requisite data and corrections.

HYGROMETRY is that part of natural philosophy which relates to the determinations of the humidity of bodies, particularly of the atmosphere:

it comprehends also the theory of the instruments which have been invented for the purpose of ascertaining the quantity of water contained in a given volume of air.

The experiments of Dr. Dalton proved that the water received from the earth is not dissolved in the atmosphere, and that it exists there in the form of vapour. That philosopher discovered also that the quantity of vapour contained in a portion of the atmosphere depends greatly upon the temperature of the latter, and that it is very variable even when the temperature is constant. He ascertained, moreover, that when a quantity of aqueous vapour at a given temperature is diffused through any space, it will support the same external pressure, whether that space had previously been void or occupied by air. On these principles are founded the methods which have been used for determining the absolute quantity of moisture in a given volume of air by means of the hygrometer, the requisite data being the elasticity of aqueous vapour at different temperatures, and the corresponding indications of the instrument.

In order to find on the scale of an hygrometer, constructed like those of De Luc and Saussure [HYGROMETER], a number of points corresponding to any given elasticities of the vapour, Gay-Lussac put water into a vessel of glass; and having determined the elasticity of the vapour arising from it, he suspended from the upper part of the vessel a delicate hygrometer. The vessel was then closely covered, so that there might be no communication between the vapour within and the external air; when, after a short time, the index of the hygrometer became stationary at a certain point on the circumference of the graduated ring which served as a scale; this point thus became an indication of the elasticity of the vapour. Experiments of the like kind being made with vapour of equal temperature, but in different states of elasticity, between those which correspond to extreme dryness and complete saturation, there were obtained so many points on the scale of the instrument as indications of the elasticities of the vapour.

The extreme points on the scale of such an hygrometer may be found in the following manner: the instrument is to be placed under a receiver in which is a certain quantity of dry caustic alkali, when, after a time, the material will contract in length as much as its nature will permit; the point on the scale at which the index stands is that of extreme dryness, and constitutes the zero point. The instrument may then be placed in water, or in a receiver filled with vapour completely saturated with moisture, when the material will expand to the greatest extent possible: the place of the index is then to be considered as the point of extreme humidity, and is usually indicated by 100.

In Great Britain the mean evaporation per minute from each square inch of the surface of water is 0.01155 grains.

The method at present adopted at the Greenwich Observatory in all hygrometrical observations, by means of the wet and dry bulb thermometers, is described in the preceding article; but in a recent work on the subject by Sir John F. W. Herschel, he states that, 'it cannot be denied that great difficulty

still exists in determining, by any mere reading of instruments, the exact hygrometric state of the air.' For the last ten years (since August 24, 1856) hourly hygrometrical observations have been made at the Observatory once in every week during twenty-four hours, the deductions from which, stated for each hour, include also that of the vapour required to saturate a cubic foot of air. They are also given, with the other meteorological elements, in the form of monthly returns.

HYLACTES, a genus of birds established by Captain Philip Parker King, R.N., for a form allied to *Megapodius*. Example, *Hylactes Tarnii*. Locality, the Island of Chiloe and Port Otway, in the Bay of Penas.

HYLEOSAURUS, Dr. Mantell's denomination for the extinct Saurian discovered by him in the forest of Tilgate, in Sussex, and thence termed the Forest Lizard. The remains upon which this genus was established were found imbedded in a block of stone $4\frac{1}{2}$ feet by $2\frac{1}{2}$ feet, and consisted principally of bones of the trunk.

HYLOBATES (from *hylobates*, 'wood-walker,' or one that goes through woods), Illiger's name for the long-armed Apes, or Gibbons. [APE.]

HYMEN or HYMENÆUS, in Grecian mythology, the god of marriage, was the son of Apollo and a muse. In very early legends he was described as a mortal of extreme beauty, who delivered from captivity some Attic virgins who had been carried to Eleusis by Pelasgian pirates. For this service he was rewarded with a maiden of whom he was deeply enamoured; and on account of his conduct, and the happiness of his marriage, he was invoked in bridal songs, thence called hymeneal songs. In ancient art he is represented as a tall and elegant, but somewhat effeminate youth—a larger and more serious Eros. He usually carries in his hand the bridal torch, and sometimes wears on his head, or around his neck, a wreath of flowers.

HYMENÆA, the name of certain festivals celebrated at Athens in honour of Hymen, the god of marriage, who is usually represented as crowned with flowers, and holding a burning torch in his hand.

HYMENÆA, a genus of plants belonging to the natural order *Leguminosæ*. *H. courbaril*, Locust Tree, or Gum-anime Tree, is a fine lofty spreading tree, and grows in the tropical parts of America and in Jamaica. The seeds are enveloped in a cellular mealy substance, which is sweet like honey, and is eaten by the Indians with great avidity. When fresh it is slightly purgative, but by keeping it loses this property. A decoction of this substance, when allowed to ferment, forms an intoxicating drink resembling beer. From the principal roots of this tree there exudes a fine transparent resin of a reddish colour, which is collected in large lumps, and sold under the name of Gum Anime. It resembles amber, is very hard, and sometimes contains leaves, insects, or other objects imbedded in it, which remain in a perfect state of preservation. It burns steadily, emitting a very fragrant smell. Dissolved in rectified spirits of wine, it makes one of the finest kinds of varnish. In countries where this tree grows the resin is used medicinally, and has also been employed in that way in Europe. The timber of the old trees is very hard and tough, and

is in great request for wheelwork, particularly for cogs. The wood is very heavy, and takes a fine polish.

HYMENOMYCETES, the first sub-order of the *Fungi*, a natural order of plants. They are characterized by their reproductive organs, called the Hymenium, being naked. This sub-order is divided by Fries into four tribes; by Berkeley into six tribes. Those of the latter are, *Pileati*, *Clavati*, *Mitrati*, *Cupulati*, *Tremellini*, and *Sclerotiacei*.

The tribe *Pileati* contains the genus *Agaricus*, many of the species of which are eatable, and are mentioned in the article AGARICUS.

In the same genus are included the various species of *Amanita*, which are among the largest and most remarkable forms of the fungi. *A. Cæsarea* is remarkable for its beauty, as well as for the traditional belief that it was in a dish of these mushrooms, which were regarded by the Romans as one of the greatest luxuries of the table, that Agrippina administered poison to her husband, Claudius Cæsar, in order to hasten her son Nero's accession to the imperial power. *A. muscaria* possesses an intoxicating or narcotic property. It is used by the inhabitants of the north-eastern parts of Asia in the same manner as wine, brandy, arrack, spruce, &c., by other nations. One large or two small fungi is a common dose to produce a pleasing intoxication, which lasts for a considerable time.

Upwards of 700 species of the genus *Agaricus* have been described; of these, 333 are natives of the British Islands.

In the tribe *Pileati* are also included eight species of the genus *Cantharellus*, which inhabit Great Britain. The *C. aurantiacus* is said to be a poisonous plant. It is common in fir-woods and pastures. It has a beautiful orange colour and a strong smell. *C. cibarius*, the common Chanterelle, is common in the summer and autumn. The pileus is of a pale yellow colour, and the whole plant has an agreeable smell, like that of apricots. On the continent of Europe this fungus is eaten, but is not often used in Great Britain. It is dangerous when eaten raw, and should always be cooked. Berkeley describes five species of this genus as natives of Great Britain. Of *Schizophyllum* but one species has been found in Great Britain, the *S. commune*. The genus *Dædalea* has been so named from the remarkable sinuosities and sculpture-like pores of its hymenium. *D. quercina* is found commonly on oak-trees, or stumps and roots of that wood. It is an astringent, and has been applied to wounds to arrest hæmorrhage. There are several other species of this genus which are indigenous in Great Britain. *D. suaveolens* is a northern plant. It yields an agreeable perfume. Upwards of forty species of the genus *Polyporus* are found in Great Britain, and many more European species have been described. Many of the species are used in the arts and in medicine. *P. destructor* is one of the fungi found on decaying timber when it is attacked with what is called dry-rot. The genus *Fistulina* has one representative in Great Britain, *F. hepatica*, the Pipe-stool. It grows upon the trunks of old oaks and other trees. It is eaten in France. The genera *Sistotrema*, *Irpex*, *Radulum*, and *Phlebia* are small. *Thelephora* is an extensive genus, and forty-two

species are indigenous in Great Britain. They are common on decaying branches of trees, &c.

The tribe *Clavati*, in their branched and club-shaped forms, resemble the corals, and were actually placed by the older naturalists in the same class. Some of the species of the *Clavati* are edible. All the *Clavaria* are esteemed as food.

In the tribe *Mitrati* the genus *Morchella* yields the esculent fungus Morel. Three species are found in Great Britain. There are also three British species of *Helvella*, as that genus is at present defined. The species of *Helvella* are edible. *H. crispa* is considered the best species for eating, and none of the species are poisonous.

The tribe *Cupulati* contains eleven British genera. Some of these plants are very remarkable, from the regular cup-like form and the deep colours they present. Of the genus *Peziza*, the species *P. coccinea* is perhaps the most elegant plant belonging to the fungi. The outer surface of the cup which it forms is white and downy, whilst the inside is of the richest carmine. It frequently grows on sticks covered with moss, the green colour of which forms a beautiful contrast with the white and crimson of the *Peziza*.

The fifth and sixth tribes of the Hymenomycetes are the *Tremellini* and *Sclerotiacei*. The *Tremellini* embrace six British genera. The British genera included under *Sclerotiacei* are amongst the lowest forms of the hymenomycetous fungi, and include species which are found attacking the various cerealia, producing the disease called *Ergot*.

HYMENOPHYL/LEE (Gr. *hymen*, 'a membrane,' and *phyllon*, 'a leaf'), a family of ferns of the natural order *Gleicheniaceæ*. The various species of the genus *Hymenophyllum* may be classed among the most elegant of the ferns, and flourish most when grown in small pots, in a mixture of peat and loam.

HYMENOPTERA, one of the orders into which insects are divided. Hymenopterous insects possess four membranous wings, of which the anterior pair are the larger; they have all the usual parts of the mouth well developed, that is to say, they possess labrum, labium, mandibles, maxillæ, and two pairs of palpi; besides the ordinary compound eyes, they are furnished with three ocelli, or simple eyes, which are usually situated on the vertex of the head. Their tarsi are five-jointed. The females are provided with an ovipositor, consisting chiefly of three elongated slender processes, of which two serve as a sheath to the third. This ovipositor, in many species, is so organized that it can not only perform its ordinary function, but serve as a weapon of defence, and is the part which in bees and wasps is called the sting: in these insects it is barbed at the apex. The antennæ are generally filiform or setaceous. The mesothorax and metathorax are well developed; the prothorax is narrow.

Insects of the order Hymenoptera undergo what is termed complete metamorphosis, i.e., the larva is unlike the perfect insect, and the pupa does not possess the power of locomotion. The larvæ of some of these insects very much resemble those of the order Lepidoptera (Butterflies and Moths), but differ in the number of their legs, &c.: these feed upon plants. The larvæ, however, generally speak-

ing, are destitute of legs, and do not possess a distinct head, and these are for the most part fed by the parent insect, or, as in the case of Bees and Wasps, by the neuters. In the pupæ, all the parts of the perfect insect are visible, since they are inclosed only in a delicate semi-transparent membrane.

In the imago, or perfect state, most hymenopterous insects live upon flowers, or at least often frequent them, some for the purpose of gathering honey, and others find them a convenient resort wherein they may prey upon the less powerful species of their own class. Illustrative forms are given on Plate 'Hymenoptera,' which see.

HYMENOPTERA, FOSSORIAL. This group, to which Latreille applies the name *Fossores*, is divided into eight families:—1, *Scoliada*; 2, *Sapygida*; 3, *Pompilida*; 4, *Sphecida*; 5, *Bembicida*; 6, *Larrida*; 7, *Nyssonida*; and 8, *Crabronida*.

HYMETTUS. [ATTICA.]

HYMN (*hymnos*), a song of praise and adoration, in honour of a Deity, and by the Hebrews, as well as the Greeks, accompanied on some musical instrument. The 'Te Deum' and 'Benedictus' are, in our liturgy, both called hymns. The hymn is a song of joy, not of lamentation. The term is now applied to any short religious poem sung in places of public worship, not being a version of a psalm, or taken directly from any of the canonical books of Scripture. Dr. Busby, in his 'Musical Dictionary,' says that 'the Hymns, or divine odes, of the ancient Greeks generally consisted of three couplets—the *strophe*, the *antistrophe*, and the *epode*. But Menander, the rhetorician, enumerates no less than eight different species of hymns. The Hymn appears to be among the most ancient of all poetical compositions; and was originally thought to be dictated by the gods themselves, or at least by men truly inspired. St. Hilary is said to have first composed hymns for the service of the church, in which he was followed by St. Ambrose and Prudentius; the latter of whom is the supposed author of those contained in the Romish breviary.' Among the ancients, however, this style of poetico-musical composition was not confined to mere religious ceremonies, but often used as a song of supplication previous to an engagement, and called the 'Hymn of Battle.' Thus Xenophon, in his account of the first battle fought by the Greeks against the Persian monarch Artaxerxes, tells us that the two armies were not more than four or five hundred paces apart when the Greeks, to the great surprise of Cyrus, began to sing the 'Hymn of Battle,' according to the custom of their countrymen.

HYODON (Gr. 'swine-toothed'), in Ichthyology, a genus of fishes of the family *Salmonida*, belonging to the *Chupina*, or herrings.

HYOSCYAMUS, a genus of plants belonging to the natural order *Solanaceæ*. One of the species of this genus, *Hyoscyamus niger* (Henbane), is an indigenous herbaceous annual or biennial plant, of which the leaves and seeds are officinal. The leaves should be collected when the plant is flowering, dried quickly, and preserved in well-closed vessels, in a cool dry place. The virtue of the leaves is dependent on the presence of *Hyoscyamia*, which, however, is more easily obtained from the seeds. When bruised they evolve an odour of henbane.

Taste oily, bitter; by expression they yield a fat oil, and also furnish a very powerful extract, as well as hyoscyamia. This alkaloid crystallizes in stellated acicular crystals, with a silky lustre; but it more generally occurs in a colourless transparent soft viscid mass. When properly dried it is devoid of odour; but when moist, and particularly when in an impure and coloured condition, the odour is highly disagreeable, stupifying, and tobacco-like. Its action, even in a small quantity, is extremely narcotic and fatal, like nicotine. It kills more slowly than conia, and scarcely causes convulsions. Applied externally to the eye, even in a very minute quantity, it causes great and enduring dilatation of the pupil.

Hyoscyamus, when taken by a person in health, produces disorder of the nervous system, inducing symptoms greatly resembling hysteria, if the dose be moderate; but if large, it causes all the phenomena of narcotic poisoning. Administered in medicinal doses to persons with disturbance of the nervous system, it lessens the irritability, quiets the circulation, and, when morbid wakefulness exists, disposes to sleep. It possesses a superiority over opium in many instances, as it does not constipate the bowels, but rather acts as a mild laxative.

In case of accidental poisoning, the stomach-pump should be used, or an emetic of sulphate of zinc be given. If the brain should appear much oppressed, venesection may also be resorted to.

HYPATIA, the famous daughter of Theon, the mathematician, was born at Alexandria, probably about the year 370. She was instructed by her father in the sciences of mathematics and astronomy, to which he was himself devoted. She succeeded her father in the chair of philosophy at Alexandria, and became the head of the Neo-platonic school there. Beautiful as she was gifted, Hypatia soon attracted to her lectures a numerous auditory. The citizens of Alexandria were proud of her, and the magistrates used frequently to consult her on important cases. St. Cyril, the bishop, came frequently into collision with the authority of Orestes, the prefect of the city, whose increasing hostility to the bishop and his clergy was by them slanderously attributed to the influence of Hypatia. At the commencement of the year 415, the monks seized her in the street, dragged her to a spot opposite to the chief church of the city, stripped her naked, and stoned her to death, after which her flesh was scraped from her bones with oyster shells, and her limbs carried to Cinaron, and there burned to ashes. Cyril has not been held guiltless of her blood, but to what extent he was implicated in the atrocious deed of his partisans cannot be accurately determined. The name of Hypatia has been made familiar to English readers in one of the best of Professor Kingsley's historical romances. For original authorities, consult the *Lexicon* of Suidas, and Fabricius, *Bibliotheca*, tom. viii.

HYPERBOLA. In connection with this article see ELLIPSE and PARABOLA. The hyperbola is one of the curves known by the name of Conic Sections. It is in the application of mathematics the least useful of the three; indeed so very rarely does the necessity of using it occur, that it may be a question whether the study of it should form a part of a course of practical mathematics. But there are, in

pure analysis, so many analogies which are illustrated by distinctions existing between the properties of the ellipse and hyperbola, that the student who aspires to more than elementary knowledge cannot dispense with the comparison of the two curves.

HYPERBOLE (*hyperbole*) means literally 'an over-casting'; in its common sense, a going beyond the truth in describing an object, not by the introduction of qualities which do not belong to it, but by the exaggeration of those which do. For example, it may be hyperbolic to say that the complexion of a fair woman is whiter than snow; but to say so of a brown woman is either irony or simple falsehood. It is often employed by orators with great effect, and Demosthenes frequently resorted to it.

HYPERICA'CEÆ, a natural order of polypetalous exogenous plants. The species inhabit various parts of the world, both within and without the tropics; they are especially common in the southern states of the North American Union. Many are objects of ornament, but they are little cultivated, because they have frequently a disagreeable hircine odour. They are generally astringent, and in some cases, as in the genus *Vismia*, yield a substance so much resembling gamboge as to have acquired in commerce the name of American Gamboge.

HYPERICUM, a genus of plants belonging to the natural order *Hypericineæ*. St. John's Wort is the common name of all the species. *H. maculatum* is the *H. quadrangulum* of Fries, and is found in moist places by ditches and rivers. *H. perforatum* is found in large quantities in Britain and throughout Europe; also in the north of Asia and Africa. The flowers are of a bright yellow colour, dotted and streaked with purple. When rubbed they emit a powerful lemon-like scent, and stain the fingers with dark purple. *H. laxiusculum* is a native of Brazil, in the provinces of St. Paul and Minas Geraes, where a decoction of the leaves is used as a remedy against the bites of serpents. *H. crispum* is a native in the regions of the Mediterranean. At the present day it grows near the sea in Attica. Most of the species of *Hypericum* are showy, and deserve cultivation.

HYPERION, a Titan, the son of Uranus and Ge, and father of Selene, Eos, and Helios.

HYPERO'DON (Gr. *hyper*, 'above,' and *odontes*, 'teeth'), a genus of *Cetacea*, or whales, of which there is only one species known. It is sometimes caught in the British Channel, and is usually from twenty to thirty feet in length.

HYPERSTHENE (Labrador hornblende) occurs crystalline and massive. Primary form a rhombic prism; colour varying from reddish to greenish-black, with a greenish-gray streak: opaque; specific gravity 3.389. It consists mainly of silica, oxide of iron, and magnesia.

HYPERSTHENE ROCK is a sort of trap, of which there are three varieties, viz., Hypersthene with compact felspar; Hypersthene with common felspar; Hypersthene with glassy felspar. In largeness of grain it varies from large-grained granite to ordinary greenstone, or is even as fine as basalt. The felspar is of various colours.

HYPERTRPHY (from *hyper*, 'above,' and *trophe* 'nutrition,') a term in medicine signifying the enlargement of a part of the body from excess-

sive nutrition. The hypertrophied organ contains no new solid or fluid substance, but one or more of its proper component tissues is in greater quantity than in the healthy state. The opposite condition of a part, namely, diminished bulk from defective nutrition, is termed **ATROPHY**.

When hypertrophy attains such a degree as to interfere with the action of the organ in which it is seated, it constitutes an important and highly dangerous disease. Such is frequently hypertrophy of the heart.

The treatment consists in the removal of the exciting cause, if this can be effected. The part should be kept at rest as much as possible, all irritation prevented, and the supply of blood diminished.

HYPO'CAUST (Gr. *hypo*, and *kaustos*, 'burnt under'), among the ancient Romans a sort of subterranean stove for heating the baths, remains of which are frequently found in Italy and different parts of England even at the present day.

HYPO'CHARIS, a genus of plants belonging to the natural order *Compositæ*. There are two British species of this genus, *H. glabra*, and *H. radicata*. They are found on waste places which are dry and gravelly.

HYPOCHONDRIASIS is a state of extreme sensibility of the nervous system, which leads patients to believe themselves worse than they really are, to detail their sufferings with exaggeration, to individualize all the painful sensations which they experience, and to consider them the symptoms of so many different diseases. Allied to this extreme sensibility there is a mental excitation, which causes the patient to pay the most minute attention to what passes within himself. He recounts all the details of his animal and organic life; relates the manner in which his digestion is effected; and describes his sensations, his passions, and the succession of his ideas.

The sufferings of hypochondriacs have been called imaginary; but such a term is not correct, if it means that they are not really felt. Of all patients, those whose diseases are the result of an excited imagination probably suffer the most. In many cases, however, these persons are affected with a real disease, and the term hypochondriasis is applicable to them only in consequence of their having their attention constantly fixed on their complaint, and of their experiencing a degree of fear and sadness which their condition does not warrant.

Hypochondriasis is frequently witnessed in young men of studious habits, and is the result of intellectual application too much prolonged. Another very fertile source of hypochondriasis is luxury, and the want of occupation and exercise. Hypochondriasis occasionally results from other causes, such as misfortunes, the excesses to which young men are sometimes addicted, and the prolonged and injudicious use of medicines.

The treatment of hypochondriasis must of course vary in some degree with its cause; but in all cases a remedy must be sought for in the banishment of their groundless fears, in a change in their mode of life, and in scenes that withdraw them from the continual contemplation of themselves.

HYPODERMIC METHOD is the name given by Dr. Charles Hunter (1865) to an expedient for the cure of acute disease, by the introduction of

various *anæsthetics* under the skin at the part affected. The plan is substantially that introduced in 1845 by Dr. Alexander Wood under the name of *Acupuncture*. As a practising physician in London, Dr. Hunter has recently carried the treatment into phases not perhaps anticipated by Dr. Wood. The mode of introducing the remedial agents has also been considerably improved. By this system, even such dreadfully acute diseases as mania, puerperal convulsions, and *delirium tremens* are said to be immediately combated and overcome, while in less active diseases, as insomnia (want of sleep), neuralgia, and other nervous and cognate affections, the most soothing anodynes can be instantaneously administered. The operation is easy, and without pain to the patient. [ACUPUNCTURE.]

HYPOGÆA (Gr. *hypo*, and *gaia*, 'under the ground'), among the Greeks and Romans, a kind of subterranean vaults for the interment of the dead, which came into use when the custom of burning the bodies had been discontinued. Sometimes these hypogæa had many apartments, with niches for the urns, &c.

HYPOGENE, a term in geology implying 'nether-formed,' proposed by Lyell as a substitute for the word *primary*, but not yet generally admitted by geologists.

HYPONITROUS ACID. This liquid at common temperatures is green, but at 0° it is colourless; it is very volatile, so that when exposed to the air it is rapidly converted into an orange vapour, the density of which is stated to be 1.72, air being 1. It consists of O3 N1. Hyponitrites may be formed by moderately heating certain nitrates, the acid of which losing two equivalents of oxygen, hyponitrous acid remains, and in combination with the base.

HYPOSEPETES (Gr. *hypo*, 'under,' and Lat. *sepes*, 'a hedge'), a genus of birds, of the family *Merulide*, and belonging to the short-footed thrushes. They are distinguished from the other genera by their forked tails.

HYOSULPHURIC ACID, in Chemistry, an acid intermediate between sulphuric and sulphurous acids, usually containing two atoms of sulphur, and five of oxygen; its equivalent being 72.

HYPOTHEC (from the Greek *hypothēke*, 'a security,' literally the subjection of a thing to the power of another person) is a term derived from the Roman law, still in use in the law of Scotland, and in that of France under the name of *hypothèque*. In the law of England it is not a received technical expression, but it is occasionally used in the same sense in which it is used in the Roman law. Hypotheca, in its proper acceptation, is that security which a man has for an obligation, when the thing which is his security is not placed in his possession, in contradistinction to pignus, which applied to what is now termed a pledge. Thus a landlord has a hypothec over the crops and furniture of his tenant; a law agent or attorney over the title-deeds of his client, in respect of his account or bill of costs; and seamen over a vessel, in respect of their wages. The second illustration we have given is always called a hypothec in Scotland, but it is clearly a lien. Further information on the Scotch law of hypothec will be found in Bell's 'Commentaries,' vol. i., and the difference between it and that of England is noticed

in Paterson's 'Comparison of the English and Scotch Law,' section 594.

HYPOTHEUSE, or HYPOTENUSE (*hypoteinousa*, 'subtending'), is a term which has always been applied since the time of Euclid to the side of a right-angled triangle which subtends, or is opposite to, the right angle.

The property of the hypotenuse of a right-angled triangle is one of the most important elementary propositions in the whole of mathematics. The property in question, in a limited form, is this: that the square on the hypotenuse is equal to the sum of the squares on the sides. The introduction of the square, however, in preference to any other figure, arises from the fact of the property of the hypotenuse with respect to the square being demonstrated before that with respect to any other figure. The general proposition is this:—If three similar figures (that is, figures of the same shape, but differing only in size) be described upon the three sides of a right-angled triangle, the content of that which is described upon the hypotenuse will be equal to the sum of the contents of the figures described upon the sides.

HYPOTHESIS (*hypothesis*, 'supposition'), literally, the act of placing one thing under another, that the latter may stand upon and be supported by the former; metaphorically, the assignment of any cause or reason why an observed event or phenomenon should have happened, or must result from a certain pre-existing condition of things. Assumed causes, or hypotheses, often have to be employed to explain natural phenomena, and ascertain real causes. Thus, when Newton became convinced of the existence of a principle of gravitation, though he had no positive proof of it, he assumed such to be the case, and in working on that hypothesis at last proved its correctness and established it as a fact. Great differences of opinion exist as to what constitutes a legitimate scientific hypothesis. Mr J. S. Mill, M. Comte, and others, consider that a sound hypothesis can only be established when the cause assigned to any phenomena is a real cause, or capable of being ascertained to be a real cause by experiment and calculation, as in the case of the law of gravitation. Dr Whewell and others, on the contrary, are of opinion that in such a case as the undulatory theory of light—which not only explains many complicated phenomena relating to that subject, but has actually led to the discovery of new facts by the inference of the truth of the hypothesis, although, as yet, the ethereal substances whose undulations are supposed to constitute light in its passage from the sun to the earth are not known to have a real existence—a sound hypothesis has been established, at least until such time as some discordant facts arise, when it must, of course, be modified or abandoned.

HYPOXIDACEÆ (Gr. *hypo*, 'under,' and *oxy*, 'sharp-pointed'), an order of herbaceous endogenous plants, with hexapetalous flowers and tuberous roots. They chiefly inhabit the warmer latitudes of India, Australia, and America.

HYRAX, the generic name for a form of quadrupeds of small size, but of great interest, in consequence of the peculiarity of their organization, which has led Cuvier and other zoologists to assign them a place among the Pachydermata, though their external appearance, when cursorily examined, would

seem to point out their relationship to the Rodentia, among which they have been erroneously classed.

Incisors, $\frac{2}{4}$; canines, 0; molars, $\frac{7-7}{7-7} = 34$.

Cuvier observes that there is no quadruped which proves more completely than the Hyrax the necessity of having recourse to anatomy for the determination of the true relations of animals. To that great zoologist we are indebted for the fact that the quadruped under consideration is a true Pachyderm, and, notwithstanding the smallness of its proportions, must be regarded as intermediate between the Rhinoceros and the Tapir. The resemblances which the Hyrax bears to the former of these may be traced, according to Cuvier, so far as the osseous structure is concerned, in the general form of the trunk. The Hyrax has 21 ribs on each side, a number superior to that possessed by any other quadruped, the Unau excepted, which has 23; and those which, after the Hyrax, have the most, belong precisely to the order of Pachydermata in which Cuvier would arrange it. Thus, the Elephant and the Tapir have each 20; the Rhinoceros has 19; the Solipeda have 18. The greater part of the Rodentia, on the contrary, have only 12 or 13; and the Beaver, which has the most, only 15.

The upper incisors of Hyrax are not formed, like those of the Rodentia, in the shape of a quadrangular prism, or in that of a cylinder curved and terminated by a truncation or a corner-edge. They are triangular, and terminate in a point, recalling to the observer the canines of the Hippopotamus. The lower incisors are laid forward, like those of the Hog; they are flat and dentilated in youth, but soon become worn by attrition against the upper incisors. The molars represent those of the Rhinoceros, both in number and form, so that, were it not for the size, they might be mistaken for each other.

The fore feet are divided each into four toes tipped with hoof-like nails; the hind feet into three, of which the innermost is furnished with a long claw-like nail. The toes are all buried in the skin as far as the little hoofs, precisely as in the rhinoceros.

Several species belong to the present genus; of these we may notice the Syrian Hyrax (*Hyrax Syriacus*), the Daman or Coney of Scripture; the Cape Hyrax (*Hyrax Capensis*); and the Tree Hyrax (*Hyrax arboreus*), which inhabits the hollows of decayed trees in the forests of South Africa.

Hyrax (*Hyrax Capensis*).

With respect to the Syrian Hyrax, Bruce states that, 'in place of holes, the animal seems to delight in less close or more airy places, in the mouths of

caves or clefts in the rock, or where one projecting, and being open before, affords a long retreat under it, without fear that this can ever be removed by the strength or operations of man.' He describes it as gregarious, and says that frequently several dozens of them sit upon the great stones at the mouth of caves warming themselves in the sun, and coming out to enjoy the freshness of a summer evening. 'They do not,' he continues, 'stand upright upon their feet, but seem to steal along as in fear, their belly being nearly close to the ground, advancing a few steps at a time and then pausing. They have something very mild, feeble-like, and timid in their deportment; are gentle, and easily tamed, though when roughly handled at first they bite very severely.' The same author says that these quadrupeds are found plentifully on Mount Libanus, and that he has also seen them among the rocks at the Pharan Promontorium, or Cape Mahomet, which divides the Ælaniticus from the Heroopoliticus Sinus, or Gulf of Suez. They seemed to him to be the same in all places; but if there was any difference, those of the Mountain of the Sun were superior in size and fatness. He kept one some time, and gives an interesting account of its habits in confinement.

HYRCANIA, a province of the ancient Persian empire, lay at the S.E. corner of the Caspian Sea. Hyrcania was a plain sloping from the mountains towards the Caspian Sea, and was very fertile, producing grapes, figs, and corn in abundance, though the land was not much cultivated. Previous to the Persian conquest Hyrcania appears to have been subject to the Chorasmii. After the dissolution of the Persian empire it became subject to the Macedonians. It appears afterwards to have become independent. Strabo informs us that there were several towns in Hyrcania, of which the most important were Talabroce, Samariane, Carta, and Zadracarta, which Arrian mentions as the capital ('Anabasis,' iii. 28).

HYRCANUS, JOHN, one of the Asmonæan rulers of Judæa. He succeeded his father Simon in the high priesthood, B.C. 135. During the first year of his reign (B.C. 134) Jerusalem was besieged by Antiochus Sidetes, and after a long siege Hyrcanus was obliged to submit; but he eventually established his independence. The latter part of his reign was troubled by disputes between the Pharisees and Sadducees. Hyrcanus originally belonged to the Pharisees, but quitted their party, and became in consequence very unpopular with the common people. He died B.C. 106, and was succeeded by his son Aristobulus, who was the first of the Asmonæan princes who assumed the royal title.

HYRCANUS II. was the eldest son of Alexander Jannæus, king and high priest of the Jews. At the death of Alexander the regal authority was assumed by his widow, Alexandra, a princess of much wisdom and virtue, and the pontificate was conferred on Hyrcanus. When his mother died (B.C. 69) he was declared king, but was soon after deprived of power by his brother Aristobulus, who was of a daring and ambitious disposition. Hyrcanus, who was a man of easy and peaceful temper, would probably have remained content with the private position to which he had been reduced, but he was persuaded by Antipater to seek the aid of Aretas, king of Arabia

Petræa, to whose court he went in the year 65 B.C. In compliance with the entreaties of Hyrcanus, Aretas marched against Jerusalem, defeated Aristobulus, who, with his partisans, took refuge in the temple, and delivered the city into the hands of Hyrcanus. Both Aretas and Hyrcanus, however, were compelled to withdraw from Jerusalem, by order of Emilius Scaurus, Pompey's lieutenant, who had been gained over by bribes and promises to espouse the cause of Aristobulus. Shortly after, the matters in dispute were submitted to Pompey by the brothers, who appeared in person before him; but the evident desire of the Roman to show favour to Hyrcanus roused the fiery temper of Aristobulus, and prevented an amicable arrangement. Aristobulus attempted for a while to resist, and the city of Jerusalem was subjected again to the privations of a siege, at the close of which Hyrcanus was restored to the office of high priest, with the title of prince. He lived several years under the protection of the Romans; but in the year 40 B.C. Syria was invaded by Pacorus, the son of the king of Parthia, and Antigonus, the son of Aristobulus, having through the influence of Pacorus gained possession of the person of Hyrcanus, cut off his ears, in order to incapacitate him for the priesthood, and sent him as a prisoner to Seleucia on the Tigris. Several years afterwards he was induced by Herod to go to Jerusalem, where, under pretence of being concerned in treasonable designs, he was put to death in his eightieth year.

HYSON, a species of green tea imported from China.

HYSSOP (*Hyssopus officinalis*), the name of a species of plant of the natural order *Labiata*. Though common in our gardens, it is not a native, but has been introduced from Siberia, or from some of the mountainous parts of Central Asia. Hyssop was wont to be a favourite with the herbalist as a tonic, and, differently prepared, as an expectorant. This plant is not the hyssop of Scripture. The shrub referred to by the biblical writers belongs to a different natural order, namely, the *Capparidaceæ*, or Caper family. 'The chief points,' says Dr. Duns ('Biblical Natural Science,' vol. ii., 272), 'to be noticed in order to identification are—1. That the hyssop spoken of as scientifically described by Solomon was relatively small. We are not entitled to assume that the cedar was the largest of trees, and the hyssop the smallest of plants, but only that, compared with the cedar, the hyssop was very small. 2. That the plant supplied stalks which, when put together, formed a bunch that could be used in sprinkling blood. 3. That some of the stalks grow to the size and strength of short rods. 4. Subordinate to these, that a plant

having such characteristics was associated, in the minds of the people, with matters of cleanliness and the public health. Between twenty and thirty different species of plants have been proposed, but no one of them comes so near the above requirements as the caper plant (*Capparis spinosa*), the *lasaf* of Lepsius and Stanley, the *aszef* of Burckhardt, and the *lussuf* of Bonar.'

HYSTASPES. [DARIUS I.]

HYSTERIA (From *hystera*, 'the womb') is, in general language, understood to signify those paroxysms to which females are subject, and which are attended with convulsions, a sense of choking, and involuntary laughing or crying. But the term is used in medicine as a general expression to include a vast number of other symptoms known as 'nervous disorders,' all dependent on a peculiarly susceptible state of the nervous system, and not confined to women, nor dependent on diseased states of the womb.

What is called the hysteric fit generally commences with the sensation of a ball in some part of the abdomen or in the left side, which rises with a twisting vermicular feeling to the throat, where it induces a sense of suffocation. A temporary state of loss of sense and voluntary power succeeds, in which the patient either lies motionless, or is agitated with violent struggles of the limbs. In the absence of convulsions there is often immoderate laughter, crying, or singing, and the paroxysm is frequently terminated suddenly by a burst of tears. More usually the patient lies quietly for some time after the convulsions cease, and when recovered complains of headache.

During a fit of hysteria, care should be taken to prevent the patient receiving injury from the head or hands striking against the floor or hard bodies, and to guard against the propensity to bite, by placing a folded cloth between the teeth. If the fit be slight, it may frequently be arrested by dashing cold water over the face, or by filling the mouth with something which has an unpleasant taste, as salt; or a stimulating scent may be held to the nostrils. If the paroxysm be more prolonged and violent, it will be proper, should the face be flushed and head hot, to apply wet cloths to the forehead, and to loosen all the dress about the neck and chest. When there is less fulness about the head, small doses of stimulants, such as sal volatile in water, will be useful.

The general nervous symptoms will frequently resist every mode of treatment. Giving tone to the system and relieving the mind are frequently the most important objects to be had in view.

HYSTRIX. [PORCUPINE.]

HYTHE. [CINQUE PORTS; KENT.]

I is a vowel which represents two very different sounds in different languages. In England it denotes a rapid pronunciation of the diphthong *ai*. In French, Italian, and many other tongues, its sound is that of the English *e*. In the series of the vowels established by the experiments of Mr. Willis, *i*, as denoting the latter sound, lies at one of the two extremes. It is pronounced with the lips retracted so as to shorten the vocal tube, whereas the same organs are protruded to produce the sound represented at the other extremity by *u*. As to the various forms of this letter see the Plates of the ALPHABET.

The letter is interchangeable as follows:—

1. With the diphthongs *ai*, *oi*, *ei*, as in the Latin language, where *alais*, *requairo*, *pueroi*, *puerois*, *nulloius*, *deico*, &c., were corrupted into *alis*, *requiro*, *pueri*, *pueris*, *nullius*, *dico*. In the same language, when one *i* was followed by another *i*, it was not uncommon to denote them by a single long *i*, as *tibicen*, *Chius*, *alius* (gen.), for *tibicen*, *Chius*, *alius*. In such cases it was common to give greater length to the letter, thus, *chiivs*.

2. The short *i* was interchangeable with nearly all the short vowels, more particularly in the penult syllables of polysyllabic words, which are very indistinctly pronounced. Thus the Greek *mēchānē* is in Latin *māchina*. In the same manner the Nomad races of North Africa are called by the Greeks *Nomades*, by the Romans *Numidæ*. *Bonitas* must have been originally *bonotas*, and would have been written in Greek with a termination *-ons*. Lastly, in a large number of words a short *u* degenerated into an *i*: as *maximus*, *decimus*, *recipero*, *scribimus* (compare *simus*), into *maximus*, *decimus*, *recipero*, *scribimus*.

3. A short *i* before *n* or *m* is not unfrequently in French changed into *ai* or *a*. *Vincere* is in French *vaincre*, &c. [A.]

4. In the same language the vowel *i* is changed into *oi* very commonly, as *sitis*, *soif*; *mi*, *moi*; *fides*, *foi*; *Ligeris*, *Loire*, &c., and this though the *i* in Latin be short.

5. *I* is often inserted in French or Spanish words before the vowel *e*. [E.]

6. The vowel *i* is often inserted after the vowels *a*, *o*, and *u*, in the French language, particularly when a contraction has taken place, as *aimer*, *connoître*, *réduire*, from *amare*, *cognoscere*, *reducere*. [A.]

7. When the vowel *i* in the Latin language has a vowel after it, and is preceded by one of the consonants *p*, *b*; *t*, *d*; *c*, *g*; the derived languages have often a sibilant in the place of the former consonant. Thus *sapiam* is in French *sache*; *rabies*, *rage*; *ratio*, *raison*; *medius*, in Italian, *mezzo* (compare the

Greek *μεσος*). The double sound of *c* and *g* in our own language may have originated in this way.

A similar change occurs in other cases, as *simia*, French, *singe*; *vindemia*, *vendange*; *lineus*, *linge*.

IAMBICS, a species of verse composed of a succession of iambi (˘ ˉ), or equivalent feet, was used both by Greek and Latin poets. The iambic is the most common metre in the Greek tragic poets.

The following feet may be admitted in the iambic metre in the Greek tragic poets, which is usually called the tragic trimeter acatalectic, because it consists of three entire metres, or six feet.

1.	2.	3.	4.	5.	6.
˘ ˘ ˘	˘ ˘ ˘	˘ ˘ ˘	˘ ˘ ˘	˘ ˘	˘ ˘
˘ ˘	˘ ˘	˘ ˘	˘ ˘	˘ ˘	˘ ˘
˘ ˘	˘ ˘	˘ ˘	˘ ˘	˘ ˘	˘ ˘
˘ ˘	˘ ˘	˘ ˘	˘ ˘	˘ ˘	˘ ˘

The anapæst in proper names is admissible in every place except the last, with this restriction, that the anapæst must be contained in one word. The comic trimeter admits the same feet as the tragic, and also a dactyl in the fifth place, and an anapæst in common words in every place but the last. Much of the beauty of the iambic trimeter depends upon the cæsure [CÆSURA], which usually occurs in the middle of the third or the middle of the fourth foot.

For an account of the other iambic metres employed by the Greek and Latin poets, see Hermann, 'Elementa Doctrinæ Metricæ.' In English poetry, where, however, the rhythm is determined by the accented syllables, the iambic metre is very common, as, for example:—

'On Lin'den, whe'n the su'n was lo'w,
All bloo'dless la'y th' untro'dden sno'w,
And dar'k as win'ter wa's the flo'w,' &c.

IAMBlichus, a Neo-platonist of the fourth century, was born at Chalcis in Cœlosyria. His reputation among his contemporaries cast into the shade the fame of his teacher Porphyry, whom he was far from equaling either in learning or in powers of mind. The literary career of Iamblichus extends from the reign of Constantine the Great to that of Julian the Apostate, whose favour he obtained, not only on account of his general adherence to and defence of the old national religion, but particularly for his 'Life of Pythagoras,' in which he ascribed to the Greek philosopher miraculous powers and acts, rivalling the signs and wonders on which the Christians not only founded the divine authority of their creed, but to which they still laid claim. Iamblichus made the perfection of man's moral nature to consist in a state of contemplative innocence. He also asserted the existence of several classes of spiritual essences, or dæmons, and attempted to determine the mode and occasions of their manifestation and opera-

tions, and the means by which man may subject them to himself, and employ their agency in the execution of his own designs.

IBERIA was the name given by the Greek writers to Spain. The Iberi are said to have occupied also Southern Gaul as far east as the Rhone. (Strabo, Casaubon, 166.) They were a distinct race from the Celtæ, who at a remote period crossed the Pyrenees, and occupied the central parts of the Peninsula, and from whose admixture with the Iberi the Celtiberi sprang. [CELTIBERI.] William Humboldt asserts that the Basque language is the remains of the old language of the Iberian race which at one time spread over Spain, Southern Gaul, part of Italy, and the islands of Corsica, Sicily, and Sardinia; and he attempts to prove this by the affinity between the proper names in those countries. Strabo observes that the Romans used the names Iberia and Hispania indifferently to denote the whole peninsula.

Iberia was also the name given by the Greeks and Romans to a country south of the Caucasus, having Albania to the east, Colchis to the west, and Armenia to the south, and corresponding to the central or principal part of modern Georgia.

IBERIS is a genus of cruciferous or brassicaceous plants, class 15, *Tetradynamia*, order 1, *Siliquosa*, consisting of annual, perennial, and slightly shrubby species, chiefly inhabiting Europe, and particularly the northern shores of the Mediterranean Sea. Two are found in the north of Europe, one of which, *I. amara*, is British. The plants have a very graceful appearance, and are cultivated in gardens as objects of ornament, under the name of Candytuft, in allusion to their having been first procured from Candia.

IBEX. [GOAT.]

IBIS. [ABOU-HANNES; TANTALIDÆ.]

IBRAHIM PACHA, viceroy designate of Egypt, was born in Roumelia in 1789. He was the son, or adopted son, of Mehemet Ali, and was intrusted by him with the command of a force to preserve tranquillity in Upper Egypt when only sixteen years of age. In 1816 he gave great proofs of gallantry and generalship in subduing the Wahabes, an Arabian sect of military fanatics, who aimed at purifying Mohammedanism, and denied the claims of the sultan to be considered the chief of Islam. For several years afterwards he afforded great assistance to his father in organizing an Egyptian army, after the European fashion, and in 1825 he invaded the Morea with the view of quelling the Greek insurrection. He captured several strongholds, but the intervention of the allied powers cut short his successes, and after the battle of Navarino he was obliged to evacuate the country. During the next four years he still further improved the Egyptian army, by creating a regular cavalry force, and in 1831 he was the instrument used to carry out Mehemet Ali's long-cherished plan of the conquest of Syria. In this enterprise he was entirely successful. Having taken Acre by storm after a siege of six months, he soon made himself master of the whole country. He was appointed governor of the Syrian pachaliks, and discharged the duties of his post for several years with rigour and ability. In 1838 hostilities were resumed between Mehemet Ali and the sultan, and Ibrahim was again successful in the field. He totally routed the Turks in the great battle of Nezib, June 25,

1839; the Turkish fleet had deserted to Mehemet Ali, and he was also supported by France. It was then that the late Lord Palmerston, with great ability, negotiated a treaty to which England, Russia, Austria, and Prussia were parties, but from which France was excluded, to enforce the submission of Mehemet Ali. When that event took place Ibrahim evacuated Syria, and was designated successor to Mehemet Ali, as hereditary governor of Egypt. He devoted the following years to agriculture and travel, and in 1848 went to Constantinople and formally received the Egyptian viceroyalty—for Mehemet Ali had become so old and childish as to be quite unfit to govern; but he did not enjoy the honour many weeks, dying at Cairo, November 9, 1848. He was a brave and skilful general, and a sagacious and stern administrator.

IBRAILA or IBRAHIL (Turkish), also called *Brailov* or *Brailoff*, is the principal port of Wallachia, 103 miles N.E. of Bucharest, on the left bank of the Danube, above Galatz. The place is fortified, and an island shelters its harbour. It contains extensive warehouses, and most of the exported produce of Wallachia, especially corn, is shipped here. The population is estimated at 20,000. The town has suffered much in the various wars between Russia and Turkey—having been thrice captured by the former power.

ICE (German, 'eis'), is water or other liquid frozen into a solid form. Water, in ordinary cases, freezes at 32° Fahrenheit, or 0° on the Centigrade and Reaumur's thermometer. The formation of ice most generally takes place on the surface first, and if the cold be sufficiently intense, it progresses downwards till the whole body of water is converted into a solid mass. Sometimes, however, ice forms at the bottom of rivers, and is called ground-ice. It is one of the universal laws of nature, that as all bodies are expanded by heat, so they are contracted by cold; and although water, when congealed by excessive cold, appears to increase in bulk and become specifically lighter, the cause is readily explained on the principles of crystallization—the word crystal originally signifying ice. Thus water in freezing crystallizes in filaments, which uniformly cross each other at angles of 60° and 120°; and by this means a piece of ice, on minute examination, will be found full of air-bubbles, or small interstices, which of course contribute to the bulk, and decrease the specific gravity. It is this angle of crystallization which causes the ice to occupy a greater volume than if the filaments were parallel. To prove that ice contains a large portion of air, we have only to drop some small pieces of ice into a glass filled with hot water; and we shall perceive that as the ice melts, the air contained therein becomes disengaged, and air-bubbles will be seen to rise to the surface of the water, and then burst. That ice is lighter than water, is known from its swimming on its surface; and also from the fact that the bulk which water occupies, when turned into ice, is as nine to eight. Thus this apparent deviation from the laws of nature does not in the least alter the general proposition, that all bodies are contracted by cold and expanded by heat. But as to the general density of ice, it is harder and much more compact in the northern latitudes than in the more temperate ones. The ice of Spitzbergen and the Greenland seas is so hard that it is difficult to break with a hammer.

It is related by M. de Bomare, that during the severe winter of 1740 there was constructed at St. Petersburg, according to the rules of architectural art, a palace of ice, fifty-two feet long, sixteen feet wide, and twenty feet high. The blocks of ice were quarried from the river Neva; and when built up, the different parts were coloured by sprinkling them over with water of different tints. To increase the effect, six cannons, made of ice, with wheels, &c., of the same material, were placed before the palace; and a hempen ball was fired by one of these cannons through a board two inches thick, at a distance of nearly sixty yards, without bursting the ice cannon. From the excessive cold which universally prevails at the poles, the water is converted into solid masses of ice, similar to the hardest rocks; and it may be formed by the chisel of the statuary, like stone or marble. This great solidity of ice at the poles is caused by the very low temperature of the atmosphere during the absence of the sun's rays; and there can be no doubt that the eternal masses of ice at the north pole are the principal source of the coldness of our winters, and that this low temperature is conveyed to our more temperate latitudes by the vast strata of cold air blowing from the north. The ice at each pole of the earth forms an immense cupola, the thickness of which, beyond the 60th degree of latitude, is several hundred feet. Captain Cook could never approach nearer the south pole, where there is no land, than the 70th degree of latitude, or about 1500 miles, although he had coasted round it for a whole summer; but later navigators have penetrated nearer the pole, though only to meet with an eternal barrier of snow and ice. In the northern part of the Russian territory the temperature of the atmosphere is sometimes sufficiently low to freeze mercury, or 71° below the freezing point of water. In the northern latitude the thermometer frequently falls to zero, or 32° below freezing point.

There are many curious phenomena connected with the formation and solution of ice. Thus water congeals in a glass which is set in salted snow, on account of the intense cold communicated to it. If only the lower part of the glass stands in snow, the congelation will commence at the bottom instead of the surface, and proceed upwards. During this process the glass will not readily spring or crack; but if it be entirely covered with salted snow, with the view of promoting congelation all over, the glass is liable to break, because the regular discharge of air is thus prevented. It is by the assistance of snow that various liquids are cooled and frozen. In India, where it scarcely ever freezes naturally, they have a very ingenious method of obtaining ice. The natives dig pits in the ground about two or three feet deep, which are lined with Indian corn, or dried sugar-canes. They then place over the excavation shallow dishes made of very porous earthenware filled with soft water. The dishes are deposited in the evening, and in consequence of the evaporation from the outside of the dishes, a considerable portion of the water is found frozen next morning. Before sunrise, the natives collect the ice, and deposit it in an underground cellar, lined with straw, where, in consequence of its own accumulated cold, it freezes into a solid mass. As to the solution of ice, it melts sooner in water than when exposed to air of a similar tempera-

ture; and sooner in water a little warm than near the fire, where there may be more heat. It melts quicker on some substances than on others, for which a philosophical reason cannot always be assigned. For instance, it melts sooner on a silver plate than on the palm of the hand; and also on a plate of copper than on any other metal. When placed in a vacuum, it sooner melts than when exposed to the atmosphere. In the former it will only occupy four minutes, while it takes twenty minutes to dissolve it in the atmosphere. [FREEZING.] *Regelation* is a remarkable property of ice. If two pieces of melting ice be placed together in a warm room, the stratum of water between them soon freezes and cements them together. A similar effect occurs beneath the surface of warm water.

ICE-HOUSE, a building constructed for the purpose of keeping ice through the summer, by excluding, as perfectly as possible, the influence of changes in the temperature or humidity of the external atmosphere. Such structures are not only useful for preserving ice which is to be applied to the cooling of liquors, or to the preparation of articles of confectionary, but also as affording the most effectual means known for keeping meat, fish, game, vegetables, and fruit sweet and fresh in hot weather.

One of the simplest modes of preserving ice consists in enveloping the ice in a great quantity of straw, above the surface of the ground, in such a position that moisture, which is even more injurious than heat, may drain off freely.

An underground ice-house may be simply a large cellar, with hollow or double walls, floor, roof, and doors, and furnished with a trapped drain to allow the escape of such water as may be produced by a partial thaw, without admitting any air. Mr. Loudon ('Encyclopædia of Cottage, &c., Architecture') gives a ground-plan and section of a complete ice-house of approved construction, of the inverted conical shape, with an arched roof, which it is proposed to cover with two or three feet of earth, or more in hot climates, over which he suggests the propriety of training ivy, for the sake of excluding solar heat. In this design a small pump is shown communicating with a well in the drain of the ice-house, for the purpose of raising the thaw-water for drinking or other use. Dr. Ure, in his 'Dictionary of Arts,' &c., article 'Ice-house,' gives a section of a similar structure, but with solid walls and a conical roof of timber, which may be simply thatched, or covered with brickwork and thatched, and which should have a gutter round it to collect and conduct to a distance all rain that falls upon it, that the circumjacent ground may be kept dry. Many other forms of ice-house have been proposed by different writers. The importation of American ice from Wenham Lake has lessened the necessity for collecting ice in England.

ICE PLANT (*Mesembryanthemum crystallinum*), a garden plant which derives its name from the numerous crystalline spots, like specks of ice, that cover its leaves.

ICE-SPAR, a mineral of a light-gray colour, found near Naples. It is sometimes crystallized in thin and long six-sided tables. Its specific gravity is 4.32; and its component parts are, silica, 63.56; alumina, 24.06; potash, 10.03; lime, 0.94; peroxide of iron, 0.92; water, 0.37.

ICE TRADE AND MANUFACTURE. The trade of collecting ice in this country is comparatively small, being confined chiefly to the neighbourhood of large towns. When the winter is favourable, the ice is collected daily from the rivers, brooks, ponds, and canals, and carefully stored in ice-houses. In the newly built and best-constructed of these houses, the outer walls are of massive brick-work; within these are walls of strong timber, and between the two casings is a compact stratum of saw-dust, a substance remarkably efficacious in checking the transmission of heat. The inclosed area is divided into four compartments, and the only door, extending from floor to roof, is narrow, and closed by a sliding-shutter, over which, on the outside of the building, is fixed a crane. When the laden carts come into the courtyard, the ice is quickly put into baskets, and emptied into one or other of the compartments, where it is strewn about equally, layer after layer, until the whole place is full. Most of the older ice-houses in this country are built underground, on the theory that the atmosphere is colder there than above, but it is now known that the exclusion of damp is a great desideratum, and that this can be better insured above ground than below. The rays of the sun do more good than harm, if the building be well constructed, because they tend to dry the air in and around the building. The French, in 1859, built an extensive range of ice-houses in the Bois de Boulogne. During the hard frost of December in that year, 250 carts were employed for ten days in conveying ice to these store-houses.

A remarkable foreign trade in ice has sprung up during the present century. About forty years ago a London fishmonger made a voyage to Norway, purchased a large quantity, brought it home, and sold it at a good profit. Since then we have regularly obtained annual supplies from Norway and Sweden. But North America is the great ice-producing country. The credit of originating the export trade to tropical countries is due to Mr. Tudor, a Boston merchant, who established an ice-trade with the West Indies in the year 1805. After much perseverance he landed a cargo of Massachusetts ice at Calcutta in 1833. He sent 180 tons, of which 80 melted on the voyage. The 100 tons were eagerly bought by the natives, and a trade thereupon commenced which has gradually extended itself to Bombay, Madras, Hong Kong, China, and Batavia. The enterprise was so successful that several ice-companies were formed in the New England states for the shipment of ice to Great Britain. It is chiefly collected in the neighbourhood of Boston, Philadelphia, Baltimore, Washington, and New York, and the lakes which supply it are very valuable property. One of the best sources is Rockland Lake, in Orange County, which yields more than a hundred thousand tons every winter. Wenham Lake, eighteen miles from Boston, is very deep, and the ice forms upon it beautifully clear. An acre yields a thousand tons on an average. When the ice is of the requisite thickness—from ten to twenty inches—it is cleared from snow, and an ice-plough, drawn by horses, is made to cut parallel grooves a few inches in depth in it, and these are again crossed by other grooves at right angles, so that the whole of the surface is deeply

marked out into small squares, measuring a little more than three feet. A saw, worked by hand, cuts out one row of blocks, and then the rest are easily severed by crowbars, and floated away to the ice store-houses, which are always very large buildings, built near the edge of the lake, pond, or stream. Two of these houses at Rockland Lake will hold 40,000 tons each, and one at Athens, on the Hudson, will hold 60,000 tons. In the interior towns of America the ice is sold at 10s. to 16s. per ton; at Boston it is sold wholesale for shipment at about 8s., and the freightage makes it worth 18s. per ton at the English ports.

The importation of ice into the United Kingdom in 1864 amounted to 24,802 tons; value, 22,823*l*.

Many experiments have been made to produce ice by artificial means, but it is only recently that they have become practically useful. Two ice-making machines were exhibited in the International Exhibition of 1862; one of which, known as Siebe's Ether Ice-machine, is capable of producing ten tons of ice per day. It is worked by steam-power, and its action consists in evaporating ether, which rises into vapour at a very low temperature, and again condensing the vapour to liquid, so as to be used afresh. By this machine 52° of cold have been obtained, and it is now successfully used under the equator, in Peru, and in India and the Cape of Good Hope by the government, for the use of the troops and hospitals. The other machine exhibited was that of Carré and Co., of Paris, in which ammonia is used instead of ether. A strong iron vessel filled with a solution of ammonia is so placed that heat can be applied to it; and a smaller iron vessel, containing ammoniacal gas, so that it can be immersed in water. When a tube connects the two vessels curious alternations take place in the ammonia, first liquid, then gaseous, then liquid again, and so on; and each process of vaporizing freezes some of the water in which one of the vessels is immersed. From its low price, and extreme simplicity, this machine is likely to come into extensive use. [REFRIGERATION.]

ICEBERGS (German, *berg*, 'a mountain') are immense masses of ice rising to a great height above the level of the sea, presenting a singular variety in form and appearance. They are masses broken off from glaciers, or from barrier lines of ice-cliff, and seem to owe their origin to the circumstance of glaciers being in a continual state of progress. The glaciers of Greenland, which are situated on the margin of the sea, protrude their exterior parts over the ocean, and in the summer when the ice becomes brittle, the force of cohesion is overcome by the weight of the prodigious masses that overhang the water, and they are detached from the glacier with a dreadful crash. Thus an iceberg is formed. It is chiefly by the north polar current, which passes through the narrow sea that separates Greenland and Iceland, and descends upon the shores of Labrador, and thence to the south-east of the great Atlantic, that the ice-formed mountains of the northern regions are borne to the south, where they are seen floating in towering masses, until dissolved by the warmer temperature of the atmosphere and water. The mountains of ice, by which the ocean is thus traversed, appear in a great variety of shapes; sometimes as *Bergs*, or mountainous masses; at others as vast sheets of ice,

called *Ice-fields*, or smaller aggregations, known as *Ice-floes*. These icebergs have the appearance of chalk or marble cliffs floating on the deep, and have been seen with an elevation of above 200 feet, and a circumference of two or three miles. We may best judge of their magnitude, when it is estimated that the portion which appears above the surface of the water is not more than one-seventh of the entire mass. Lieutenant Parry, during the first Arctic expedition under Captain Ross, measured an iceberg which was grounded in Baffin's Bay, at about twenty miles from the land, and in sixty-one fathoms of water. It was found to be 4169 yards long, 3869 broad, and 51 high. The weight of the whole was calculated to be 1,292,397,673 tons. They are so numerous that Dr. Scoresby counted 500 drifting along in lat. 69° and 70° N. The great distinction of icebergs from ice-fields, independently of their shape, is, that the former are fresh-water formations, which have their origin upon the land, and are identical with the glaciers of the Alps and other mountain ranges, but having their birthplaces in the frozen regions of the North Pole. These floating masses of ice are very dangerous to navigation. (See Scoresby's *Arctic Regions*, and Noble's work, *A Painter in Search of Icebergs*.)

ICELAND, a large island in the North Atlantic, belonging to Denmark, extends from $63^{\circ} 24'$ to $66^{\circ} 33'$ N. lat., and from $13^{\circ} 30'$ to $24^{\circ} 30'$ W. long. Its area is about 40,000 square miles. The population, which was formerly 100,000, has been reduced by epidemic disease till, at the last census, the number of inhabitants was only 64,603. The coasts are deeply indented with fiords, which are the estuaries of the rivers that flow from the interior. The island is crossed from east to west by rugged mountains, which run nearer to the south than to the north coast, the longer rivers flowing towards the north. From these ridges numerous offsets branch out, to terminate in high and steep promontories. Between these offsets, in the vicinity of the fiords, are fine valleys, in which the inhabitants have erected their dwellings; and many of the low mountains are covered with a coarse grass, which affords summer pasture to their cattle. The best inhabited spots are on or near the banks of the fiords, where factories are built for the purpose of trade and shipping. But the majority of the inhabitants live in detached cottages or farms, a certain number of which constitute a parish, having a church and an incumbent of the episcopal Lutheran communion. The interior of the island is a dreary desert. It consists partly of snow mountains, called Yökuls, many of which are also volcanoes, and partly of vast tracts covered with lava, scoriæ, and volcanic sand. There are also several lakes, the largest of which, called Myvatn, is about 40 miles in circumference. The most extensive mass of icy mountains is that called Klofa Jökul, in the south-east part of the island.

There are numerous boiling springs, such as the Geysers, which throw up, at periodical intervals, columns of boiling water to the height of 200 feet; the Reykiuim and the sulphur springs of Krisuvik are near the south-west coast; those of Reykiadal in the west district; and those of Reykiahverf and Krabla in the north. There are also bogs of boiling mud, craters of volcanoes now quiescent, and columns

of dense smoke and steam issuing from many spots. The whole island appears to be of volcanic formation, and there are still numerous volcanoes in full activity; among which are Hecla (5210 feet high), Öräfa Jökul (6426 feet), and Snaefells (5965 feet).

Owing to the insurmountable obstacles presented by conglomerations of ice, and by lava fields once red-hot but suddenly cooled, and thus rent, torn, and twisted in every conceivable manner, a portion of the country towards the south-east coast has hitherto defied all investigation, and will probably for ever remain untrodden.

There are thirty known volcanoes in Iceland, eight of which have been active within a century. The most destructive eruptions on record were those of 1294, 1341, 1636, 1693, 1783, and the eruption of Mount Hecla, 2nd September, 1845, to 6th April, 1846, on which occasion the ashes reached the Orkney Islands. The climate is very variable—storms of extreme violence being frequent; in summer it is moist, and in winter the sky is dark and gloomy, but lighted up by brilliant displays of the Aurora Borealis. The south-west coasts, washed by a prolongation of the Gulf Stream, are much milder than the north, and generally free from ice. The temperature is more elevated than in any other country in the same latitude.

Forests formerly abounded, but the island is now destitute of trees, except a few stunted service-trees and birches. The want of fuel is severely felt, although the Gulf Stream and the Polar currents occasionally float drift-wood to the northern shores, and a fine white turf is used. Sulphur is exceedingly abundant. Iron ore is also found. Garden vegetables are cultivated, but no grain of any kind can be raised. The most important domestic animal is the sheep, which, with the horse, ox, pig, and dog, was introduced from Norway during the last century. It is estimated that there are about 700,000 sheep, 25,000 head of cattle, and 32,000 horses on the island. Reindeer, introduced in 1770, now roam in large herds, but are not domesticated; and the polar bear is sometimes cast on the shores from the northern ice-fields. Birds are numerous; and several kinds of fish are abundant on all the coasts. The wool of Iceland is much sought by English manufacturers, and the commerce consists of the exchange of that article, butter, skins, fish, and oil, for European manufactures.

The only means of transport is by pack-horses, and in winter on sledges. The Icelanders are attached to their country, and hospitable to strangers. There is only one school, the college at Reikiavik, with a president, eight professors, and eighty to a hundred students; but domestic education is general, and the people are intelligent, being universally educated to the extent of reading and writing. Reikiavik is the only town, but there are upwards of twenty trading villages, mostly on the coasts. From thirty to forty vessels sail annually from Denmark to Iceland. Formerly the trade was a government monopoly, but it was thrown open by a decree of the Althing in 1853.

The inhabitants are the genuine descendants of the old Scandinavians or Norsemen; they are tall, but not generally corpulent, with a florid complexion, flaxen hair, and an open frank countenance. The

women are shorter and more inclined to corpulence than the men. Scurvy and elephantiasis are common, owing to the sameness and poor description of the food, and the crowded and ill-ventilated dwellings, which are generally of the very humblest description, built of turf or pieces of lava, the crevices stuffed with moss and the roof formed of turf. The knitting of stockings and gloves is almost the only industrial occupation.

The Icelandic language is the standard of the northern or Scandinavian dialect of the Gothic language. Since the language has been no longer spoken in Scandinavia (Norway, Sweden, Denmark), it has been styled exclusively Icelandic. The first colonists of Iceland were Norwegians, who fled in the ninth century from the dominion of Harold Harfager, tyrant of Norway. They established a republican government, appointed magistrates, and had their annual Althing, or national assembly, which was held at Thingvall, in the south part of the island. Icelandic literature began to be cultivated immediately after the introduction of writing, in 1057. Iceland fell under the yoke of Norway in 1264, and when that country became subject to Denmark in 1380, it shared its fate. It was not, however, transferred with it to Sweden in 1814, but continued under Denmark. The Icelanders are generally good sailors, and it is now indisputably proved that they not only discovered Greenland, but also America, which they called Vineland, early in the tenth century. Christianity was not established in the island till 1000. The Protestant form of worship became general about 1550. In the seventeenth century the island suffered much from the ravages of the Algerine pirates, who carried away many of the inhabitants to slavery, and its population has on several occasions been decimated by famine and disease.

Within the last century literature has been much cultivated by the Icelanders; and the language and literature of Iceland have begun to attract attention among the scholars of Denmark, Germany, and England. Three newspapers are published at Reikiavik, and Icelandic books are also printed.

Iceland is divided for administrative purposes into three fiordnungs, or districts. These districts are divided into syssels, or sheriffdoms, a sysselman being a magistrate and receiver of the king's taxes residing in each of them. The governor-general is called *stiftamtman*, appointed by the king of Denmark for five years, and resides at Reikiavik. He has under him two *amtmanns*, or deputy-governors—one for the western, and the other for the northern and eastern districts. The affairs of the island are regulated by the Althing, a council composed of twenty members—one for the town of Reikiavik, and one for each of the nineteen syssels.

Reikiavik (reek-town), the capital, contains about 1200 resident inhabitants, and is built on the south side of an inlet of the Faxefjord, on the south-west coast of the island. It consists of two streets, and contains the chief buildings of the island. The houses, with a few exceptions, are simply small wooden dwellings, one story high, and coated with tar, with which white painted sash windows contrast strongly. The town has an observatory and library, is the seat of the Icelandic Society, and a bishop's see. To the south-west of Reikiavik is the peninsula

of Alftaness, adorned with a church and a number of pretty cottages. Gardé, in the same neighbourhood, is the residence of the archdeacon of Iceland; and at Hafnarfiord there is a dry dock.

In the northern district there is a kind of town or village, called Eyafjordur, and a factory, called Husavik, on the Skialfiandafjord, from which sulphur from the neighbouring mines is shipped. Other factories are scattered about the coast, especially in the west.

The best works of reference on Iceland are Sir George Mackenzie's *Travels*, a cheap edition of which was published in 1851; *Tracings of Iceland and the Farøe Islands*, by R. Chambers, 1856; *Iceland: its Volcanoes, Geysers, and Glaciers*, by C. S. Forbes, 1860; *Iceland and its Sagas*, by Baring-Gould; Dr. Henderson's *Iceland*; Lord Dufferin, *Letters from Northern Latitudes*; Symington, *Pen and Pencil Sketches of Iceland and the Farøe Isles, &c.*

ICELAND-MOSS. [CETRARIA.]

ICELAND SPAR, [CALCAREOUS SPAR.]

ICH DIEN (literally, 'I serve'), the motto of the Prince of Wales, which was originally adopted by Edward the Black Prince, after the battle of Crecy, in proof of his obedience to his father, Edward III., and has been continued down to the present time. (See an exhaustive paper on this subject in the *Archæologia*, vol. 31, by Sir Harris Nicolas.)

ICHNEUMON, the name applied by Lacépède, Geoffroy, and others, to a genus of digitigrade carnivorous quadrupeds, allied to the Gennets (*Genetta*, Cuvier) and Paradoxures (*Paradoxurus*, F. Cuvier). It is the *Mangusta* of Oliver and others, *Herpestes* of Illiger, *Mangouste* of the French.

Feet short, with five demipalmated toes armed with slightly retractile claws; tongue furnished with horny papillæ; ears small; anal pouch voluminous, simple; body elongated; tail long, strong at the base; hairs of the fur annulated. Teeth, forty, consisting of—

Incisors, $\frac{6-6}{6-6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{6-6}{6-6}$.

Locality, India and Africa.

Examples, *Herpestes Pharaonis*; *H. griseus*;

Ichneumon Pharaonis.

H. badius; *H. vitticollis*; *H. fasciatus*; *H. gambianus*, &c.

The Egyptian Ichneumon (*H. Pharaonis*) was celebrated by the ancients for its destructiveness

among snakes and other reptiles; and many exaggerated accounts relative to its darting into the crocodile's mouth and tearing the monster's entrails were received as truth. It was one of the sacred animals of the Egyptians, and was occasionally kept tame. It is a bold and familiar animal, preying upon snakes, crocodile's eggs, rats and mice, poultry and other birds, much resembling, in fact, a polecat in its manners. In size it exceeds a common cat. The general colour is freckled gray; the long tail is terminated by a black tuft. Locality, Northern Africa.

ICHNEUMON, a genus of insects belonging to the order *Hymenoptera*, section *Terebrantia*, and family *Pupivora*, in the arrangement of Latreille. The genus, as defined by Linnæus, included such pupivorous hymenoptera as are furnished with veined wings (the anterior pair presenting in their disc several complete or closed cells), filiform or setaceous vibratile antennæ composed of a great number of articulations, and an ovipositor of various lengths and complicated structure. The Linnæan genus now constitutes a group including a great many well-marked genera, and an immense assemblage of species. All these are remarkable for the habits of their larvae, which are parasitic in the bodies of other insects. These bodies the perfect Ichneumons perforate by means of their ovipositors, and there lay their eggs. This destructive habit gave rise to the name by which they are known; a comparison being drawn between them and the Egyptian ichneumon, the quadruped celebrated as the destroyer of serpents and crocodiles.

ICHNITES (Gr. *ichnos*, 'a foot-step'), in geology, those traces of foot-prints peculiar to the new red sandstone formation, which appear to have been impressed generally by reptiles and birds. The subject has been classed under two general divisions, viz., *Ichnolites*, or foot-prints on stone, and *Ornithichnites*, or stony bird-tracks. Of the former, some interesting discoveries were made in 1828 by Dr. Duncan, on the new red sandstone, in the quarry of Corn Cockle Muir, in Dumfriesshire. The tracks were discovered in many successive layers of stone, to the depth of forty feet. In 1834 some remarkable footsteps were also discovered at Hesseburg, in Saxony, the hind foot of one of the largest animals being eight inches in length. [*CHEIROTHERIUM*] Of the *Ornithichnites*, some very distinct traces were discovered, in 1836, in the red sandstone of the Connecticut Valley, and in other parts of Massachusetts, several specimens of which are now in the British Museum. These footmarks are referred to that class of birds called Waders, and the impressions were very similar to those made on the muddy banks of the river by the living aquatic birds common to the localities where these traces were found. Thus, by these faint traces, we are enabled to gain some notions, however indistinct, of the great history of Nature and of the first dawnings of animal existence in the history of the earth's crust.

ICHNOCARPUS, a genus of plants belonging to the natural order *Apocynaceæ*. *I. frutescens* is a native of Ceylon and Nepal. The flowers are small and purple; the leaves deep green above and pale beneath. *I. Afzelii* is a native of Sierra Leone,

and about the river Bascha, in woods and among bushes.

ICHOLOGY (Gr. *ichnos*, a 'footprint'; *logos*, 'a discourse'), literally, the science of fossil footprints. The word has almost wholly superseded two other words which were much in use early in this century, namely, *ornithichnites*, or bird footprints, and *saur-oidichnites*, or saurian footprints. Ichology is now studied as a subordinate branch of palæontology, to which the late Dr. Hitchcock has given the name *Lith-ichnozoa*, or animals made known by their tracks in stone. Having arranged the whole animal kingdom in ten groups, Dr. Hitchcock gives sixty genera and 120 species of animals which are known only from their footprints, and which are found in the State of Massachusetts alone. This fact will show how wide the field is which is here opened up to the student of natural science. Such progress has been made in the science of comparative anatomy, that, having ascertained the form of any one part of the bony skeleton, the form of all the rest can be determined. Thus, if an animal has left the print of its toes, or of the whole foot, on any, even of the oldest, rocks, from these tracks the figure of the whole animal may be known with some degree of certainty. Science is specially indebted to the late Dr. Hitchcock for the application of the principle of correlation implied here, in determining the kind of animal to which the footprints belonged.

ICHTHYOCOLLA (Gr. *ichthys*, 'a fish,' and *kolle*, 'glue'), a preparation from the fish known by the name of Huso; a kind of isinglass.

ICHTHYOLITES (Gr. *ichthys*, 'a fish,' and *lithos*, 'a stone'), in geology, a name given to those numerous fossils of the vertebrated order, some of which exhibit the most perfect animal structure, while others appear to be but a little removed from the humbler crustaceans. Agassiz divides these ichthyolitic remains into four orders of fishes, each characterized by the form and structure of their scales; thus a single scale often becomes a clue to the order and habit of the animal to which it belonged; and it is remarkable that the scales are precisely those of the finny tribes which are most abundant in a fossil state. The leading classification of scales is into enamelled and unenamelled. The former are divided into the *Placoidians* (broad-plated), and *Ganoidians* (shining); while those not enamelled are subdivided into *Ctenoidians* (comb-like), and *Cycloidians* (discus-shaped); but those only of the Placoidian and Ganoidian races are found in the ancient strata anterior to the chalk formation. The Ctenoidian and Cycloidian orders, to which the existing species of fish principally belong, make their appearance in the earth's crust after all the preceding fossil genera had become extinct.

Agassiz distinguished the different kinds of fossil fishes by another feature, dividing them into three classes—the *Round* tail, as in the wrasse;—

the *Crescent* tail, as in the trout;—

and the *Unequal* tail, as in the shark.

It is remarkable that nearly all the fossil fishes found in the ancient strata, beneath the magnesian limestone, are distinguished by these unequal tails; while in the superior or oolite systems, this form is seldom discovered.

Cuvier, in his great work on 'Fossil Organization,' had effected much towards the classification of fishes; but it was reserved for his distinguished successor, Agassiz, to complete the arrangement. He has raised the number of species to about 2000. His discoveries in the old red sandstone formation have been of the most extraordinary character; and their strange conformations, as he observes, would puzzle the naturalist to assign them even their class. 'Boat-like animals,' says he, 'furnished with oars and a rudder; fish plated over like the tortoise, above and below, with a strong armour of bone, and furnished with but one solitary rudder like a fin, covered with scales; creatures bristling over with thorns; others glistening in an enamelled coat, as if beautifully jappanned; the tail, in every instance among the less equivocal shapes, formed not equally, as in existing fish, on each side of the central vertebral bone, but chiefly on the lower side, the bone sending out its diminished vertebrae to the extreme termination of the fin. All the forms testify of a remote antiquity, of a period whose fashions have passed away. The figures on a Chinese vase or an Egyptian obelisk are scarcely more unlike what now exists in nature than the fossils of the old red sandstone.'

ICHTHYOLOGY (from *ichthys* 'a fish,' and *logos* 'a discourse'), a department of zoology embracing the structure and natural history of fishes. [FISH; FISHES, FOSSIL.] To the views and labours of Agassiz allusion has already been made under the foregoing articles. The geographical distribution of fishes some years ago attracted much attention; and several valuable local monographs were published, which on this point added greatly to our knowledge. Among these may be enumerated Bennett's 'Fishes of Ceylon,' with exquisitely coloured plates, and Yarrell's 'British Fishes,' with admirable woodcuts. Nor are other labourers wanting. In the north of Europe, besides the writings of Nilsson and Eckstrom, the fishes of Denmark have been illustrated by Henrik Kroyer. Those of Belgium have

been carefully examined by M. de Selys Longchamps. In that naturalist's 'Faune Belge,' fifty-three fresh-water fishes and forty-one species inhabiting the sea are enumerated. Of the former, forty-three live only in fresh water; six in fresh water, but go to the mouths of rivers in winter; and four live in the sea, but migrate to the rivers in spring or summer. Of the sea fishes thirty pass up the Schelde as far as Antwerp. The fresh-water fishes of central Europe have engaged the attention of Agassiz. Freyer has published an account of those inhabiting Carniola, amounting to thirty-two species. Italian ichthyology has been admirably illustrated by Charles Bonaparte, the prince of Musignano. In Asia the fishes of the Caspian have been described by Eichwald in his 'Fauna Caspio-Caucasica,' published in 1841. Those inhabiting the rivers of Syria have been enumerated by Heckel from the collections of Kotschy. Fifty-seven species inhabit the rivers Orontes and Euphrates, of which no fewer than forty-five are *Cyprinidae*. Indian ichthyology has received valuable contributions from McClelland, whose papers have been chiefly published in the *Calcutta Journal*. In Siebold's 'Fauna Japonica' are accounts and figures of Japanese fishes by Temminck and Schlegel. The most valuable contribution ever made to our knowledge of the ichthyology of Eastern Asia was communicated to the British Association at Cambridge in 1845, in the form of a report on the 'Ichthyology of China,' by Dr. Richardson. From his researches it would appear that the fishes of that region are not only very numerous as regards species, but also very valuable on account of the extensive fisheries there carried on. His remarks on their distribution are highly interesting. It would appear that chains of islands or coasts having an east and west extension determine the extent of the range of species and groups of species. For example, to take the intertropical zone of the ocean, we find a great number of fishes common to the Red Sea, the coasts of Madagascar, the Mauritius, the Indian Ocean, the south of China, the Philippines, the Malay Archipelago, the northern coast of Australia, and the whole extent of Polynesia, including the Sandwich Islands. As regards the generic forms of the fresh-water fishes, China agrees with the peninsula of India. Were the vast zone in question, embracing more than two-thirds of the circumference of the globe, to be suddenly elevated, we should find the remains of fishes similar everywhere throughout, the species which have a local distribution being few and unimportant. This result of Dr. Richardson's researches is of the highest importance when brought to bear on geological considerations. Dr. Richardson has also been engaged in the special investigation of the ichthyology of Australia, and his many valuable memoirs on that subject may be consulted in the 'Transactions of the Zoological Society,' and in the 'Annals of Natural History.' In Dieffenbach's 'Travels in New Zealand,' the same indefatigable and philosophic zoologist has published, in conjunction with Mr. Gray, a list of the fishes of New Zealand. Ninety-two species are there enumerated. In Smith's 'Illustrations of the Zoology of South Africa,' figures and descriptions are given of the fishes of the Cape of Good Hope. The researches of Dr. Peters on the eastern coast of Africa made

us well acquainted with the ichthyology of that interesting region. With those of the northern part of Western Africa we have had information in the valuable memoirs of Lowe on the fishes of Madeira. The labours of Jenyns on the fishes collected during the late Admiral Fitzroy's voyages have contributed materially to our knowledge of the ichthyology of the southern extremity of South America, whilst that of Guiana has been illustrated by Sir Robert Schomburgk, in the 'Naturalist's Library.' De Kay's 'Zoology of New York,' and later publications, have made us acquainted in detail with the fishes of the United States. They amount, so far as known, to 440 species, distributed through 156 genera and 32 families. In the state of New York there are 126 *Acanthopterygii*, 115 *Malacopterygii*, 3 *Lophobranchii*, 18 *Plectognathi*, 3 species of sturgeon, and 27 cartilaginous fishes.

ICHTHYOPHIS (Gr. *ichthys*, 'a fish,' and *ophis*, 'a serpent'), a genus of fishes of the Eel kind, of the family *Murinidae*.

ICHTHYOSAURUS (from *ichthys*, *sauros*, literally, 'Fish-lizard'), the generic name given by Mr. König to the extinct fossil animal noticed by the

late Sir Everard Home, under the appellation of *Proteosaurus*, and by Wagler under the name of *Gryphus*.

We are indebted to the late Sir H. T. De la Beche and the Rev. W. D. Conybeare principally for pointing out and illustrating the structure of this extraordinary creature; and that at a time when the materials were far more scanty than they are at the present day. Dr. Jäger, Mr. Hawkins, Dr. Buckland, Sir Philip de Malpas Grey Egerton, and Professor Owen, have all contributed to throw light on the organization of a being that has long ceased to exist; and the anatomy and animal economy of this tyrant of the seas of former ages is now nearly as well known as that of the porpoise, which revels in the ocean that washes the shores of our existing continents and islands.

'If,' writes Dr. Buckland, 'we examine these creatures with a view to their capabilities of locomotion, and the means of offence and defence which their extraordinary structure afforded to them, we shall find combinations of form and mechanical contrivances which are now dispersed through various classes and orders of existing animals, but are no

Ichthyosaurus communis.

longer united in the same genus. Thus, in the same individuals the snout of a porpoise is combined with the teeth of a crocodile, the head of a lizard with the vertebræ of a fish, and the sternum of an *Ornithorhynchus* with the paddles of a whale. The general outline of an *Ichthyosaurus* must have most nearly resembled the modern porpoise and grampus. It had four broad feet or paddles, and terminated behind in a long and powerful tail. Some of the largest of these reptiles must have exceeded thirty feet in length.' These aquatic reptiles fed upon fishes, as is proved by the mass of fish scales (chiefly referable to the *Pholidophorus limbatus*) intermingled with coprolite throughout the entire region of the ribs, and in the more matured coprolites themselves. They also devoured other animals and even the weaker of their own species. Their prey was transmitted into a stomach which must have been nearly coextensive with the cavity of the body, and the contents were thence made to pass through an intestinal canal which appears to have resembled, as Dr. Buckland observes, the spiral intestines of some of the swiftest and most voracious of our modern fishes.

Armed with enormous jaws and teeth, and furnished with huge glaring eyes, protected by bony sclerotic plates, and constructed either for subaquatic or aerial vision, the *Ichthyosauri* were admirably adapted for their oceanic home, and their life of oceanic warfare. They could give chase to their prey along the surface, pursue it into the depths,

and reascend with the utmost rapidity. In fact, their whole structure befitted them for an aquatic abode, and betokened their carnivorous appetite. Several species have been discriminated, and it is probable that a rigorous examination may bring others to light. We may enumerate as examples *Ichthyosaurus communis*; *Ich. tenuirostris*; *Ich. intermedius*.

Ichthyosauri abound throughout the lias and oolitic formations. The chief repository has been hitherto considered to be in the lias at Lyme Regis; but, as Dr. Buckland states, they abound along the whole extent of this formation throughout England, from the coasts of Dorset, through Somerset and Leicestershire, to the coast of Yorkshire. The lias of Germany and France contains them. 'The range of the genus *Ichthyosaurus*,' says Dr. Buckland, 'seems to have begun with the Muschelkalk, and to have extended through the whole of the oolitic period into the cretaceous formation. The most recent stratum in which any remains of this genus have yet been found is the chalk marl at Dover, where they have been discovered by Dr. Mantell: I have found them in the gault near Benson, Oxon.' (See Dr. Mantell's *Medals of Creation, and Wonders of Geology*; Professor Owen, *Paleontology*; Lyell, *Principles of Geology*, &c., &c.)

ICICA, a genus of plants belonging to the natural order *Burseraceæ*. *I. heterophylla* is a tree 50 feet in height, growing in Guiana, on the banks of the river Couron. When an incision is made in the bark of

this tree, a yellow balsamic aromatic fluid exudes, which retains its fluidity a long time after exposure to the air. A resin is found also in the seeds, and the natives of Guiana carry the nuts about with them on account of the scent they give out. The Caribs also use the exudation for mixing with oil with which they anoint their bodies. *I. heptaphylla* is a small tree, a native of the woods of Guiana, possessing the same properties as the former species. There are many species of *Iceia*, all of which yield a resinous sweet-scented gum.

ICOLMKILL. [IONA.]

ICONOCLASTS (Gr. *eikon*, 'image,' and *klaō*, 'I break') signify those who object to the use of images, statues, pictures, or other representations of sacred objects in the church. At many various times in ecclesiastical history have movements been directed to the putting down of image-worship. In the sixth and seventh centuries the bishops of the Eastern Church condemned the popular practices regarding images, and the use of them by Christians was alleged to be an obstacle to the conversion of the Jews, and one of the causes of the progress of Mohammedanism. In the year 726 the Emperor Leo III., of Constantinople, commanded the removal of all images, except that of Jesus Christ, from the churches. Again, in 730, he prohibited all acts of reverence to them under pain of death, and ordered all such images, wherever found, to be destroyed. Notwithstanding the opposition of the Popes Gregory II. and III., Leo and his successor Constantine Copronymus persevered in their iconoclastic propensities. The subject created great agitation in France and Germany in the time of Charlemagne.

The usage of the Greek Church at the present day allows pictures, but rejects statues or graven images. At the Reformation the reforming party generally repudiated all use of images in worship as idolatrous, but Luther permitted the simple use of them for purposes of instruction. Hence, in the Lutheran churches of the present day, pictures, crucifixes, &c., are the usual ornaments. The Roman Catholic Church has ever retained such symbols in its services. As a rule the Protestant churches may be considered very iconoclastic, though the High party in the English Church have of late years endeavoured to reconcile the use of crucifixes, images of saints, and other sacred representations, with the provisions of the Rubric. (Schlosser, *History of the Iconoclast Emperors*; Gibbon; Stanley, *Lectures on the Eastern Church*.)

ICOSAHEDRON (Gr. *eikosaedros*), a solid figure bounded by twenty planes. It has twenty equal faces, each of which is an equilateral triangle; thirty edges, and twelve solid angles, each formed by the meeting of five plane angles.

ICOSA'NDRIA, the twelfth class in the sexual system of botany invented by Linnæus. The name was applied by Linnæus to plants having an indefinite number of stamens inserted into the calyx, such as the melon, pomegranate, plum, &c.

ICTERIA (Gr. *ikteros*, 'the jaundice'), a genus of birds of the family *Merulida*, and belonging to the short-footed thrushes.

ICTIDES, a name given by M. Valenciennes to the Benturonga, a genus of plantigrade carnivorous quadrupeds, which had been formerly referred by

F. Cuvier to the genus *Paradoxurus*. It is the genus *Arctictis* of Temminck.

General Character.—Head rather short, muzzle pointed; ears, which are small, tufted with long hairs; tail long, hairy, prehensile; five toes on each foot. Dental formula:—

$$\text{Incisors, } \frac{6}{6}; \text{ Canines, } \frac{1-1}{1-1}; \text{ Molars, } \frac{5-5}{5-5} = 36.$$

Geographical Distribution, India, Malacca.

Between the Viverrine family and that which is composed of the racoons and bears there had existed a considerable gap, which is now in a great measure filled up by the newly-discovered forms, the Benturong and the Panda. The external appearance of the *Ictides* corresponds in the same degree with both that of the civets and racoons, having the plantigrade motion of the latter and the slender snout of the former. It is indeed completely plantigrade, and has on each foot five toes armed with strong compressed claws, apparently adapted for climbing. 'Its tail, the thickness of which at its commencement is almost monstrous, is prehensile beneath, without being terminated by a naked skin, like that of the Ateles, but resembling entirely the tail of the Sajous. The eye, like that of the domestic cat, has the pupil vertically elongated; the habits of the *Ictides* are consequently nocturnal. The ears are small and rounded; and the nostrils are surrounded by a muzzle, which is divided into two portions by a deep sulcus. The hairs are long and thick, and a peculiar character is given to the physiognomy by the moustaches, which are very voluminous on the lips, the eyes, and the cheeks, and by the pencil of long and numerous hairs which terminates the ears. The cry is intermediate between those of a cat and a dog.'

Three species are recorded: we select *Ictides albifrons*.—Fur gray, hairs long, silky, black at the base, and white in their extreme third, shorter on the head and limbs; sides of the snout, forehead, pencils of the ears (which are edged with white) black; upper part of snout and forehead white; iris yellow; belly gray, with shorter hairs than those on the upper parts of the body. Size, that of a very large domestic cat. In another specimen the sides of the snout, and the tail, its extremity excepted, were gray. Locality, Bootan, Nepaul. Sir Thomas Stamford Raffles describes the gait of this Benturong as low and crouching, the body being long and heavy, and the legs short. The tail, thick at its insertion, gradually tapers to the extremity, where it curls upwards. In climbing trees the animal is assisted by this tail, which is strong.

IDA. [CANDIA; TROY.]

IDEA (*ἰδέα*, from the root *id*, 'to see'), in its widest and now generally received acceptation, is used to indicate every representation of outward objects through the senses, and whatever is the immediate object of thought. Like many other terms of mental philosophy, it is derived from the most eminent of the senses, that of vision. In the Platonic philosophy, the word *idea* signified primarily, the archetypes of all created things as they subsist in the divine intellect; and, secondarily, the conceptions of the human understanding, by means of which the essence of a thing is conceived. Plato's

own definition is very extensive: 'an idea may be attributed to whatever, as a plurality, may be indicated by the same name.'

For the term *idea* the schoolmen employed the word *species*, by which, Cicero tells us, the Greek word *idea* was usually rendered in Latin ('Top.' 7), though he himself proposed the term *form*, which has been adopted by Kant and his followers to designate that constant element in the perception of outward objects which is independent of matter, and which the mind presents to itself in accordance with its own laws. These species the schoolmen divided into sensible and intelligible, of which we shall here extract Hobbes' succinct account. 'The philosophyschools teach that for the cause of vision the thing seen sendeth forth on every side a visible species, (in English) a visible show, apparition, or aspect, or a being seen, the receiving of which into the eyes is seeing. . . . Nay, for the cause of understanding also, the thing understood sendeth forth an intelligible species, that is, an intelligible being seen, which coming into the understanding makes it understood.' ('Of Man,' part i., c. 1.)

According to Locke, 'Ideas are whatever is the object of the understanding, whatever a man thinks, or whatever it is the mind can be employed about thinking.' In this large sense the word is generally employed by English and French writers, and also by the Germans before the time of Kant, who ascribes to *idea* a higher but limited signification. By *idea* Kant eminently designated every conception formed by the reason (as distinct from the understanding), and raised above all sensuous perception. These ideas he subdivides into, 1st, empirical, which have an element drawn from experience, for instance, organization, a state, a church; and, 2nd, pure, which are totally free from all that is sensible or empirical, such as liberty, immortality, holiness, felicity, deity. Another division of the Kantian ideas is into theoretical and practical, according to a similar division of the reason itself. Thus the idea of truth is a theoretical idea, that of morality a practical idea. The best work on the various theories, and the author's opinion respecting them, is the 'Lectures on Metaphysics,' by the late Sir W. Hamilton, published under the editorial supervision of the Rev. H. L. Mansel and J. Veitch, in 1859, which the reader may compare with the strictures of John Stuart Mill and others.

IDE'ALISM, the theory that denies the existence of material bodies, and makes everything to consist in ideas.

IDENTITY signifies sameness. In this sense it is employed in the phrase personal identity, where it signifies the invariable sameness of the thinking subject, or the *I*. In a secondary sense it denotes a merely relative identity, which may also be called logical or abstract. Thus, in logic, whatever things are subjects of the same attribute or collection of attributes are considered the same; e.g., dog and lion are the same relatively to the common notion quadruped under which they are both contained. Again, in physics, a tree may be asserted to be the same in relation to all the rights of property, notwithstanding the physical change it undergoes from the constant segregation of old and aggregation of new particles. Lastly, it is only in this logical use of the term that

we can be said in memory to be conscious of the identity of the reproduced and the original idea; for if they were absolutely identical, it would be impossible to distinguish between the first appearance and the recurrence of an idea.

According to Butler it is impossible to define the idea of personal identity, but it is easily ascertained; for a comparison of one's self in any two moments of our existence suggests immediately the idea, and at the same time the identity of ourselves.

IDES. [KALENDAR.]

IDIOPATHIC (Gr. *idios*, and *pathos*), a disease which is independent of any other disease, and consequently opposed to those diseases which are symptomatic.

IDIOSYNCRASY, literally means a peculiar temper or disposition, and is the name given to any constitutional peculiarity, whether physical or mental. Uncommon partialities or dislikes, unlooked for effects produced on persons by ordinary causes, and unusual conditions of body or mind, are usually termed *idiosyncrasies*.

IDIOT and **IDIOTCY**. An idiot is one who never had any understanding from his infancy; and *idiocy* is the non-development of the mental faculties, or the state of an idiot. There are, however, many degrees of deprivation—some being as helpless as infants, others able to engage in some simple work, while a few have been known to maintain themselves by their own industry. It is a great mistake to place the idiot and the insane in the same category, though this is often done.

M. Séguin defines a typical idiot as one who knows nothing, can do nothing, and cannot even desire to do anything, which condition must certainly be regarded as the maximum; and it has been observed that it would be hardly possible to find such a being as this, little above a sensitive plant, fashioned externally as man, but shorn of all other human attributes. Yet such instances as these do occasionally occur. Idiots have been divided into three classes by Dr. Howe, no mean authority, who observes:—'Idiots of the lowest class are mere organisms, masses of flesh and bone in human shape, in which the brain and nervous system have no command over the system of voluntary muscles; and who, consequently, are without power of locomotion, without speech, without any manifestation of intellectual or affective faculties. Fools are a higher class of idiots, in whom the brain and nervous system are so far developed as to give partial command of the voluntary muscles, who have consequently considerable power of locomotion and animal action, partial development of the affective and intellectual faculties, but only the faintest glimmer of reason, and very imperfect speech. Simpletons are the highest class of idiots, in whom the harmony between the nervous and muscular system is nearly perfect; who consequently have normal powers of locomotion and animal action, considerable activity of the perceptive and affective faculties, and reason enough for their simple individual guidance, but not enough for their social relations.' Generally speaking, these descriptions will be found to meet the various degrees of *idiocy*. Still there is nothing more difficult to define, nothing of which it is less possible to find a standard. The word *idios* points

to a human being isolated from his fellows, and no better term, in the midst of the many used to designate his condition, has been found than that of *idiots*. The words folly, imbecility, fatuity, stupidity, and others employed by various writers, are but different expressions of the same thing.

Diminutive stature is usually regarded as, in most cases, a symbol of idiocy, but no dimensions of the head, except in the extremest diminutiveness, or other measurements often relied upon, can be regarded as true criteria of imbecility. It is very curious, however, that the result of the examination of more than two hundred cases showed that in an immense number the sides of the face were unequal, in many the palates were inordinately arched, and in some the two sides were unsymmetrical, in others the palate was excessively flattened, while in some it was prominently keeled, and in a few the palate bones did not meet. Their dentition also was found to be peculiar, and the tongue in an abnormal condition—the size being sometimes larger than common, and occasionally inordinate. That therefore so many are mute, or semi-mute, or indistinct in utterance, is no wonder. These corporeal defects are attended by uncleanly habits, gluttony, peculiar unhealthy looks, an awkward and irregular gait, an involuntary flow of saliva, and automatic motions of the head, limbs, tongue, and lips; while the ear heeds not the instruction it receives, and the eye sees the light, but makes no definite distinction of form, colour, or size. Yet nothing further can be safely stated as a generalization than that, as a rule, the perceptive powers are defective, the fancy frivolous, and the whole bearing more or less eccentric. Some are vociferous, grinning, and facetious; others mutter, mope, and sulk, and are very vicious. Again, many are mild, affectionate, and tractable, while others are violent, depraved, filthy, and repulsive. As previously stated, the classification of idiots is indeed no easy task, and it is well said by Dr. Howe—‘The highest of the lower class of idiots can hardly be distinguished from the fool, the least stupid of fools can hardly be distinguished from the simpleton, and the highest among simpletons stand very near the level of hundreds who pass in society for feeble-minded persons, but still for responsible free agents.’

Causes of Idiocy.—Even at the present day the causes of idiocy are but very imperfectly understood. It is generally considered that it is sometimes the consequence of moral impressions, accident, or disease on the part of the mother, as in the case of the deaf and dumb; or it may commence during infancy from bad nursing, want of nutrition, or constitutional disease. But we are far from knowing certainly how it has happened that human beings have been born, in whom the harmony of nature has been so disturbed by the excesses or defects of physical constitution. It is due from society to the thousands of its members who are so blighted and bowed down, to make accurate investigation into all their peculiarities, with a view to beneficial operations.

Statistics of Idiots.—It has been asserted that the British isles contain 50,000 idiots or imbeciles, but we have no certain means of verifying these figures, on account of the census reports making no distinction between the idiots and the insane. That there are many thousands, however, is placed beyond a

doubt by the annual reports of the Poor Law Board, which state that in the different unions and parishes of Great Britain there are generally about 35,000 insane paupers, of whom nearly 20,000 are idiots.

Institutions for Idiots.—It is only during the present century that any efforts, on a large scale, have been made for the amelioration of the condition of idiots, and at the present day the number of asylums established is by no means equal to the national requirements of society. Desultory efforts were first made in Paris, Berlin, Switzerland, &c.; but little permanent good was effected till the year 1846, when an asylum was set up by the authorities of Massachusetts, which example was quickly followed in Pennsylvania, New Jersey, and New York. Great Britain also at this time became alive to the necessity of special provision for the idiot. The first practical endeavour for this object was made at Bath, where four pupils were placed under the care of a matron, and with such success, that the institution was afterwards removed to an airy, elevated situation, and now contains about two dozen pupils, the number of which it is still desired to augment. In 1847 the interest of a lady living in London was greatly excited on this subject by reading two articles which appeared in *Chambers' Journal*. She saw the well-known philanthropist, Dr. Andrew Reed, on the matter, and he, with others, induced the then lord mayor, Sir George Carrol, to preside at a meeting to institute an idiot asylum; the result of which was the hire of Park House, Highgate, with several acres of land surrounding it. Here, in six months, the change was so great, that Dr. Connolly declared he could scarcely believe the pupils to be the same who had been originally received, and whose first gathering together was so shocking a scene, that in some spectators it induced disgust, and in others despair. The success of the Highgate asylum having awakened the benevolent interest of the queen, and received her majesty's patronage, the establishment was soon visited by her lamented consort. The building speedily became too small for the numerous applicants, and it was necessary to form a branch institution till one large national asylum could be erected. For this purpose Essex Hall, Colchester, a commodious and handsome building, the property of Sir Morton Peto, was obtained upon advantageous terms, and a few of the pupils were removed thither. At length, in 1853, his royal highness Prince Albert laid the foundation of the National Asylum at Earlswood, near Redhill, Surrey; and such was the interest taken in the work, that about 10,000*l.* were placed before him as offerings on the foundation stone. The asylum was opened in 1855 by the prince in person; and the inmates of Essex Hall were then transferred to the new building. The latter place has, however, been continued as a separate institution for the eastern counties, and is still in effective operation.

The Earlswood asylum was incorporated by royal charter in 1862. From the report of the board of management issued in 1865, it appears that the number of children then in the asylum was 404 (some of whom are elected for life, others for periods of five years), and, but for want of space, many more would be admitted. The Commissioners of Lunacy, in their annual report, amongst other approving remarks,

say:—'We have inspected every part of this institution, have examined personally all the inmates, and have had satisfaction in observing the progress generally made. The system of combining bodily exercise and drill with the instruction given in the schools, seems to be worked successfully. The children sing together with good effect, and accompany with their voices the morning and evening prayers, a portion of every Thursday afternoon being given to practising them in sacred music.' Of the personal habits of the children generally, the report appears to be very favourable, nearly all being found to be amenable to improvement. The committee's report further states that the number of inmates in the asylum is greater than that for which it was constructed, and the board feel it is desirable that the building should be very considerably enlarged. They wish to double its capacity, so as to receive 800 inmates—a number that competent authorities allow can be managed most efficiently and economically. The asylum is open to idiotic and imbecile persons from all parts of the United Kingdom, either by payment or election, excepting (in the latter case) those who are more than sixteen years of age at the time of their being brought before the board for approval as candidates, and paupers who are provided for by the law of the land.

The 25 & 26 Vict. c. 43—'an Act to provide for the education and maintenance of pauper children in certain schools and institutions'—enables the guardians of a union to contract with the managers of any institution, supported wholly or in part by voluntary contributions, for the education of idiotic persons, and to pay for their maintenance and education a sum not exceeding the cost of their relief in the workhouse.

The success of Earlswood Asylum has directed the attention of philanthropists to the special claims of the idiot, and has tended to the initiation of several institutions in various parts of the country; and every assistance in the way of encouragement and suggestion has been given to their originators by the kind and obliging medical superintendent, Dr. Down. In Scotland the benevolent work was commenced at Aldovan, near Dundee, by Sir John Ogilvy. Dr. Brodie began similar operations in Gayfield Square, Edinburgh, and now superintends the new Scotch asylum at Larbert, near Falkirk, which is intended for the reception of 200 pupils, and is zealously aided both in the capital and at Glasgow.

Education and Occupations of Idiots.—The possibility of teaching an idiot to read, write, and cast accounts depends much on taking advantage of personal peculiarities, and a perseverance which knows of no limit to its repetitions of the same thing till the conquest is achieved. The first step is to eradicate bad habits, and as soon as possible to engage the pupils in some occupation, rewarding their efforts with praise and encouragement. These employments are of the simplest kind, as the unravelling cocoa-fibre for mats, splitting rods for baskets, and preparing horse-hair for mattresses. Besides these gentle inducements to daily work, the improvement of the bodily condition is a matter of hourly and daily care. It would be wearisome to enumerate the school methods in the various institutions. All that can be said is, that they are furnished with the most

ingenious appliances, and something new is being continually added. Varied and clever use of the black board is productive of great effects. The master draws on it some animal, and sees if the pupil can tell what it is, and distinguish one part from another. Boys who have commenced learning in this way have become great proficient in drawing, and one youth at Earlswood especially so; his drawings having attracted the attention of the most celebrated of modern artists of animal forms, Sir Edwin Landseer: yet it was six months before he could be taught to distinguish with certainty a dog's head from his tail—a fact which was mentioned to the late Prince Consort, when he inquired if the youth whose drawings he was admiring could ever have been an idiot. Some subjects are taught to a large number collectively. The multiplication tables are sung, accompanied by various movements of the arms and legs. Reading, writing, arithmetic, drawing, and, in the lower classes, letters and figures, counting, imitation, speaking, weighing, telling the time, colours, and other simple things, are taught to less numbers together. As the pupils advance, of course the teaching advances also; to writing from dictation, to reading in classes, to object-lessons, and to instruction in writing, arithmetic, and drawing.

Nothing is more remarkable than the cheerful aspect of the schools, workshops, and other portions of the establishment at Earlswood, where these various employments are carried on. The learners enter into their work with surprising pleasure; and it is a curious fact that they frequently perform examples in the rules of arithmetic quickly and accurately, without knowing their names properly or their meaning.

In the girls' school, efforts have been successfully made to introduce domestic work as a part of the lessons. Bedmaking, scrubbing, and the processes of household economy are systematically taught, and afford agreeable diversion from the more strictly scholastic labour.

The amusements in summer and winter are carried out with much spirit. The monthly winter concerts are sources of great pleasure. The love of music is almost universal among the inmates, and the efforts of the staff in this direction have been amply rewarded by the delight which they have been able to inspire.

Nearly all the inmates who are considered competent to undertake it are encouraged to follow some industrial occupation—such as shoemaking, tailoring, carpentering, mat-weaving, and farming—and the interest which they manifest, and skill which they exhibit in it, is often surprising.

Nothing is more striking in many idiots than their susceptibility of religious impressions and instruction. It is most certain that many who were once profane and vulgar have been thus brought into the sunlight of religious purity and decency, taught the fear of God, and the necessity of keeping his commandments, with a sense of moral obligation seemingly beyond the scope of their limited capacities.

We have derived much of the preceding information from an admirable article on 'Idiot Asylums' in the *Edinburgh Review* for July, 1865. Other works of reference on the subject are:—'*Traitement Moral, Hygiène et Education des Idiots et des autres*

Enfants Arriérés,' &c., par Édouard Séguin; Paris, 1846: 'Remarks, Theoretical and Practical, on the Education of Idiots and Children of Weak Intellect,' by W. R. Scott, Ph.D.; London, 1847: 'Teaching the Idiot,' by the Rev. Edwin Sidney, A.M.; London, 1854: 'The Causes of Idiocy,' Edinburgh, 1858: 'The Idiot and his Helpers,' by W. Millard, Essex Hall, Colchester, 1864: 'The Training of Idiotic and Feeble-minded Children,' by Cheyne Brady, Esq., M.R.I.H.; Dublin, 1864.

IDOCRASE, *Vesuvian*, *Pyramidal Garnet*, &c. This mineral occurs crystallized and massive; the crystals are either attached or imbedded. Primary form a square prism. Colour various shades of brown, black, gray, blue, green, and yellow. Lustre vitreous-resinous. Translucent and transparent. Specific gravity 3.08 to 3.4.

The massive varieties are amorphous; the structure is fibrous, granular, or compact. The component ingredients of this mineral are silica, alumina, lime, oxides of iron and manganese.

IDOL, **IDOLATRY** (Gr. *eidolon*, 'an image,' *latreia*, 'worship'). An idol is an image worshipped as a god, and the act of worshipping such an object is called idolatry. From the very earliest times people have fallen from the worship of the true God into idolatry, and adored the creature instead of the Creator. The numerous varieties of idolatry may be reduced to four systems:—1. *Nature-worship*, or the worship of the vegetable and mineral kingdom—chiefly trees, stones, and pillars. 2. *Animal-worship*, for which purpose many animals have been held in sacred reverence by various nations. 3. *Star-worship*, or astrology, which at first addressed itself to the heavenly bodies themselves; then to their symbol, fire; and finally descended to idolatrous representations of the sun, moon, stars, &c., as the worship of Baal, Moloch, Adonis, &c., testify. 4. *Anthropolatry*, or the worship of representations of the human form. With this class of idolatry we are familiar through the mythology of Greece, Rome, Egypt, and India, and from the specimens of idols brought home from heathen lands by our missionaries. Most of the various forms of idolatry will be found under separate articles, as **FETICHISM**, or described under the countries where they have been practised.

IDRIALINE, a substance derived from a mineral, found in the quicksilver mines of Idria, which imparts to sulphuric acid a beautiful blue tint.

IDUMÆA (Ἰδουμαία), usually called Edom in the New Testament, included, in the time of Christ, a considerable portion of the southern part of Palestine, and extended S.W. as far as the Lake Serbónis; but in the Old Testament it was used to designate the mountainous district N. of Arabia, which extended from the S. of the Dead Sea to the Bay of Elana in the Red Sea. The Edomites, who were descendants of Esau, originally dwelt on Mount Seir. They were governed by kings from the earliest times, and appear to have possessed considerable power when the Israelites invaded Canaan. They were defeated by Saul, and were made tributaries of the Jews during the reign of David.

After the division of the Jewish kingdom, the Edomites continued subject to Judah till the reign of Joram, when they again established their independence. They were subdued again during the

reigns of Amaziah and Uzziah; but in the reign of Ahaz the Syrians seized upon Elath, and drove the Jews out of Edom. Edom, in common with the rest of Syria, appears to have been subdued by Nebuchadnezzar; but after the downfall of the Babylonish empire, the Edomites are again mentioned as an independent people. They appear about this period to have been driven from their original settlements by the Nabathæi, who are supposed to have been descended from Nebajoth, the eldest son of Ishmael. The Edomites were constantly at war with the Jews after the return of the latter from Babylon, till they were entirely subdued by John Hyrcanus. From this time the Edomites were regarded as a part of the Jewish nation, and were governed by a prefect appointed by the Asmonæan princes of Judæa. One of these governors, Antipater, a native of Idumæa, was appointed by Julius Cæsar procurator of Judæa, and was succeeded by his son, the celebrated Herod, who put an end to the dynasty of the Asmonæan princes.

The Idumæans marched to the assistance of Jerusalem when it was besieged by Titus, and entered the city; they did not, however, continue till it was taken, but returned to their own country laden with plunder. We have no further mention of the Idumæans in history. Origen, in his 'Commentary upon Job,' informs us that the name of Idumæa did not exist in his day, and that the inhabitants of the country were called Arabs, and spoke the Syriac language.

Ptolemæus is the only author who applies the name of Idumæa to the country west of the Jordan. The whole of Judæa was frequently called Idumæa under the Roman emperors.

IDYLL (Greek, εἰδύλλιον; Lat. *Idyllium* or *Edyllum*) is a poem, in which the appearances of external nature, or manners and sentiments, are described, or both. The bucolic poems of Theocritus are called idylls; and all the bucolic poetry [**BUCOLICS**] may be included under this name, though the ancients did not, any more than ourselves, confine the name to pastoral poetry. The 'Idylls of the King,' by Tennyson, are epic in their style and treatment, and romantic and tragic in their incidents. The Greek Idyll has been styled by Sterling an anecdote drawn from rustic life, and rounded into song.

IGLAU. [**MORAVIA**.]

IGNATIA, a genus of plants, of the natural order *Loganiaceæ*; one of the species of which produces the St. Ignatius beans of India, erroneously said to be a specific for cholera.

IGNATIUS, one of the apostolic fathers. He was one of the earliest successors to St. Paul (if not the next) in the presidency over the Christian church at Antioch. During the persecution of that body by Trajan, Ignatius refused to abandon his opinions, and accordingly was sent to Rome, where he suffered death in a very cruel manner, being thrown to the lions in a public spectacle. What little remained of the feeble old man was gathered by a few friends, removed to Antioch, and preserved as sacred relics. The martyrdom of Ignatius (which took place about 107), is celebrated in the Roman Catholic Church on February 1st, and in the Greek Church on December 20th. During the last twenty years the writings of Ignatius have been made the subject of much controversy, and it is now generally admitted

that the ordinary Greek text has been seriously tampered with, and many passages interpolated relating to episcopal authority and the Deity of Christ.

The writings of St. Ignatius which have been handed down to us, are seven short epistles addressed to the Romans, the Philadelphians, the Smyræans, the Magnensians, the Traillians, the Ephesians, and to Polycarp. An English translation may be found in Archbishop Wake's 'Genuine Epistles of the Apostolic Fathers,' London, 8vo., 1693.

IGNATIUS, Patriarch of Constantinople, was born in 799, and was the son of the Emperor Michael Curopalata, who, on the revolt of Leo the Armenian, surrendered to him the throne, and embraced the monastic life. His sons followed the example of their father, and the youngest, Nicetas, then aged fourteen, changed his name into that of Ignatius. The new emperor separated the several members of the family of Michael, and caused his two sons Eustratius and Nicetas to be made eunuchs.

Ignatius was admitted into the order of priesthood by Basil, bishop of Paros, in the Hellespont. Under the regency of the Empress Theodora, Ignatius was elected Patriarch of Constantinople. In consequence of his refusal to join the young Emperor Michael in an attempt to overturn the rule of his mother, he was deprived of his see. But he was eventually restored by the authority of a council presided over by the legate of Pope Adrian II., and from that time was allowed to rule the Greek Church without opposition. He died on the 23rd of October, 878, on which day the Greek and Roman Churches still celebrate his memory.

IGNATIUS LOYOLA. [JESUITS.]

IGNEOUS ROCKS, the materials poured forth by active volcanoes, either in a molten state, or as ashes, lapilli, and scoriæ, such as lava and basalt. They belong to all geological periods, but the most recent are necessarily the most distinct. They must not be confounded with metamorphic or plutonic rocks, and are, strictly speaking, only those which before eruption existed in a molten form. [GEOLOGY.]

IGNIS FATUUS, a meteor resembling a flame, which floats in the atmosphere at a few feet above the surface of the ground. It is generally observed by night, either stationary or in motion, over marshes or burial grounds; and sometimes, after becoming invisible, it reappears. Occasionally such meteors have been observed to follow or advance towards a spectator; but in general they appear to recede on being approached, and it has happened that, from their resemblance to the flame of a distant lamp, they have led the unwary traveller into dangerous swamps. Hence they have been named 'Jack with a lantern,' 'Will o' the wisp;' ignorant people ascribing their appearance to evil spirits.

A plausible hypothesis which has been proposed in order to account for this phenomenon is that a phosphuretted or a carburetted hydrogen gas, produced by the decomposition of animal or vegetable substances, rises from the ground or from stagnant water, and takes fire by electricity or spontaneously, at a spot where the atmosphere is particularly free from moisture. Spontaneous ignition is well known to take place occasionally in a number of vegetable and

animal substances while undergoing decomposition, in consequence of the inflammable matter coming in contact with common air or with oxygen gas.

IGNITION, INCANDESCENCE. These terms refer to that property of bodies, by which they give out light when raised to certain high temperatures, the quantity of light increasing with the temperature within certain limits. At first it is of a dingy red, or worm-red as it is sometimes called, then bright red, then an orange or yellow tint, and lastly white heat, when the light is painful to the eye. Sir Humphrey Davy's experiments placed the degree of incipient luminosity in the dark at about 810°; but a dull red visible in daylight is probably equal to 1000°; a full red heat 1200°; an orange heat 1700°; a white heat 3000°; and the high white heat of a good wind furnace (according to Daniell) about 3300°. These remarks apply to bodies which can be raised to these high temperatures without changing their state. Most bodies are destroyed before they attain the temperature necessary for ignition, and if heated in the air they inflame and undergo combustion.

IGNORAMUS (Lat. 'we do not know'), the endorsement formerly written by a grand jury when there was not sufficient foundation for the prosecution. It corresponds to the words 'not a true bill,' which are now used. The ordinary use of the word ignoramus now is to signify a foolish fellow, a vain ignorant pedant.

IGNORANTIA JURIS, or *Ignorance of the Law*, does not legally excuse a man from the consequences of offences against it. If it were not so, and crimes or social delinquencies were allowed to go unpunished because the offender was ignorant of the law, it would be placing a premium upon ignorance, and such a plea would lead to endless inquiries as to the state of a man's mind. It is, however, sometimes taken into account when passing judgment, and a more lenient punishment awarded.

IGUALDAS. [CATALUÑA.]

IGUANA, a restricted genus of Saurian reptiles, belonging to the section *Pleurodonta* of the family *Iguanidae*.

The *Pleurodonta*, with the exception of one genus, are all confined to America, and are characterized by the teeth being implanted, not along the ridge of the jaw, but in a furrow along the side of the jaw, to which latter they adhere by one side of the bony substance of the root without being implanted in the jaw itself, like a nail in a board.

The genus *Iguana*, as at present restricted, contains, according to M. Bibron, only three species, natives of Brazil, Cayenne, the Antilles, the Bahamas, Mexico, &c. They attain to considerable dimensions, and have a fierce and strange aspect. Their flesh is esteemed a delicacy.

The Iguanas (or Guanans) are characterized by a cutaneous expansion like a pendent dewlap, or flaccid pouch, under the lower jaw and throat, which is capable of being inflated; and there are cuticular folds on the lateral regions of the neck and throat. The head is stout at the base, moderately long, and of a somewhat pyramidal shape, covered with plates forming a sort of tessellated pavement. The scales of the body are small, almost lozenge-shaped, slightly keeled, and but little imbricated. A serrated dorsal

crest, consisting of elevated, compressed, and pointed scales, runs along the ridge of the back, and also of the tail to its tip. The tail is of great length, very flexible, and laterally compressed. The orifice of the ear is covered by a large tympanic membrane, and generally there are several large scales about the angle of the lower jaw. The limbs are long; the toes unequal, rough, with elevated points on the under surface, and armed with acute claws. A range of tuberculous pores runs along the inside of each thigh. The colour of the Iguana is yellowish green below, and above of a green more or less deep, becoming sometimes bluish, and sometimes a slate-colour.

The Iguanas, of which three species are known, are arboreal in their habits, and feed principally on vegetable aliment; indeed, in the stomachs of the numerous specimens examined by M. Bibron, nothing but leaves and flowers were found. Captain Belcher found in the island of Isabella swarms of Iguanas which appeared to be omnivorous, feeding voraciously on eggs, on the intestines of fowls, and on insects.

These animals haunt the borders of water, into which they often plunge and swim with great velocity, lashing their tail from side to side. During the pairing season the male is very savage, watches over his mate, and defends her with fury. The female deposits her eggs along the margin of rivers, in savannahs, or on the sea-shore, burying them in the sand. Both the eggs and the flesh of these animals are in great request, inasmuch that in some of the islands where the Iguana was very common, as, for example, Jamaica, it is now very rare. They are taken by nooses, in traps, or nets, and sometimes are hunted by dogs. They are very tenacious of life, and as they struggle violently, snapping at every person, are generally dispatched as soon as captured.

The Common Iguana (*Iguana tuberculata*, the *Iguana delicatissima* of Daudin) is a native of Brazil, Cayenne, the Antilles, and the Bahamas. It attains to a considerable size, sometimes measuring six feet in length, including the long tail. Formerly this species was an important article of commerce in the Bahamas, and cargoes of living Iguanas, or salted Iguanas, and also of their eggs, were imported into the Carolinas. The practice was to sew up the mouths of the living animals in order to prevent them from biting. They were as eagerly sought after by the epicures of the Carolinas and other places as the turtle is by the epicures of our island.

IGUANIDÆ, an extensive family of Saurian reptiles, divided by MM. Duméril and Bibron into two subfamilies, viz., *Pleurodonta* (Pleurodontes) and *Acrodonia* (Acrodonates). In the *Pleurodonta* the teeth are not implanted in the ridge of the jaw, but are affixed in a furrow along the side of the jaw, adhering to the latter by one side of their bony root. The *Pleurodonta*, with the exception of one genus (*Brachylophus*, an Indian group), are all peculiar to the New World and the adjacent islands. The genus IGUANA may be regarded as a typical form.

The *Acrodonia* are distinguished by the teeth being seated on the ridge of the jaws, to which they are soldered, and of which they appear to be a continuation. This subfamily is distributed through Asia, Southern Europe, Africa, and Australia.

The genera comprehended under the family group *Iguanidæ* are very numerous; those of the *Pleuro-*

donta constitute five tribes, viz., *Anolians*, *Polychrians*, *Iguanians*, *Tropidolepidians*, and *Ophurians*. Those of the *Acrodonia* constitute four tribes, viz., *Galeotians*, *Agamians*, *Phrynocephalians*, and *Stelionians*.

IGUANODON, the name of an extinct gigantic reptile, whose remains were discovered by Dr. Mantell in Tilgate Forest, Sussex. In its characters this fossil Saurian closely approaches to the genus *Iguana*, and there can be no doubt that it was herbivorous; indeed Cuvier, at first sight, took the teeth for those of a rhinoceros. The teeth exhibit two kinds of provision to maintain sharp edges along the cutting surface, from their first protrusion until they were worn down to the very stump. The first of these is a sharp and serrated edge, extending on each side downwards, from the point to the broadest portion of the body of the tooth. The second provision is one of compensation for the gradual destruction of this serrated edge, by substituting a plate of thin enamel, to maintain a cutting power in the anterior portion of the tooth, until its entire substance was consumed in service. Whilst the crown of the tooth was thus gradually diminishing above, a simultaneous absorption of the root went on below, caused by the pressure of a new tooth rising to replace the old one, until, by this continual consumption at both extremities, the middle portion of the older tooth was reduced to a hollow stump, which fell from the jaw to make room for a more efficient successor.

The size of this giant of the Weald in former ages was enormous. In Dr. Mantell's collection there is a portion of a femur twenty-two inches in girth in the smallest part. The thigh-bone, then, of the Iguanodon exceeded in bulk that of the largest elephant, and its length is on good grounds calculated to have been from four to five feet. Dr. Mantell carefully compared the bones of the Iguanodon with those of the Iguana, and, by taking an average from eight separate parts of the respective skeletons, he gives the following as the dimensions of the Iguanodon:—

	Feet.
Length from snout to end of tail, ...	70
Length of tail, ...	52½
Circumference of body, ...	14½

Geological Distribution.—The Wealden freshwater formation of the south of England, intermediate between the marine oolitic deposits of the Portland stone and those of the green-sand formation in the cretaceous series; Tilgate Forest; Isle of Wight; Purbeck; Rag-quarries, near Maidstone.

I.H.S., the initial letters of *Iesus Hominum Salvator*, 'Jesus, the Saviour of Mankind.'

IKENILD STREET, one of the four great roads formed by the Romans in England. It commenced at Tynemouth, in Northumberland, and passing southward through Derby, Lichfield, &c., terminated at Southampton.

ILCHESTER. [SOMERSETSHIRE.]

ILDEFONSO, S. [CASTILLA-LA-VIEJA.]

ILE-DE-FRANCE, one of the old provinces of France, was bounded N. by Picardie, W. by Maine and Normandie, S. by Orléanais, and E. by Champagne. It now forms the departments of Seine-et-Oise, Seine-et-Marne, Aisne, Oise, and parts of Eure-et-Loire, Loiret, and Yonne. Paris was its

capital. This province formed part of the monarchy under the first kings of France, and was governed by the dukes or counts of Paris, who were numbered among the great vassals of the crown. It was united to the crown in the year 987 under the reign of Hugues Capet.

ILEUS, or ILIAC PASSION, is the name given to a severe form of intestinal disease, characterized by violent griping pain around the umbilicus, spasm and retraction of the muscles of the abdomen, obstinate costiveness, and vomiting. These symptoms are, however, common to several very different conditions of the bowels, as colic, hernia, intussusception, &c. The *iliac region* is the side of the abdomen between the ribs and hips.

ILEX is a name given to two very different plants. As that of a species, it indicates the Evergreen Oak of the south of Europe, or *Quercus Ilex*. As that of a genus, it belongs to the common Holly, *Ilex aquifolium*. This latter is common in the middle of Europe, and the southern side of the range of the Caucasus, where it is only a bush, and it probably extends far to the eastward. It is chiefly valued as an ornamental tree, but its fine-grained, heavy, compact timber is used for a great number of useful purposes, especially by the turner and mathematical instrument maker. The berries are poisonous, producing purgative and violent emetic effects.

Besides the common Holly and its numerous varieties, the genus *Ilex* comprehends a large number of species, the most remarkable of which are the *I. Balearica*, or broad-leaved species of Minorca, a very handsome kind, which is hardy in the middle and south of England; the *I. vomitoria*, or Cassena Tree of the North Americans, whose leaves possess strongly marked emetic qualities; and the *I. Paraguayensis*, or Maté plant, of whose leaves a very large consumption takes place in South America under the name of Paraguay Tea. The leaves are dried, and afterwards used like the common tea.

ILFRACOMBE. [DEVONSHIRE.]

ILIAD. [HOMER.]

ILISSUS. [ATTICA.]

ILIUM. [TROY.]

ILK. A term used in Scotland to denote each, every; as, *ilk* one of you, every one of you; and also to signify the same; as, for example, Macintosh of that *ilk* means a gentleman whose surname and the title of his estate are the same; that is, Macintosh of Macintosh.

ILKESTON. [DERBYSHIRE.]

ILLE-ET-VILAINE, a department in France, formed out of a portion of the old province of Bretagne, is bounded N. by the English Channel and the department of La Manche, E. by the department of Mayenne, S. by that of Loire-Inférieure, and W. by those of Morbihan and Côtes-du-Nord. It lies between 47° 37' and 48° 31' N. lat., 1° and 2° 13' W. long., measuring 74 miles from N. to S., and 55 from E. to W. The area is 2597 square miles. The population in 1863 was 584,930.

Surface.—The department is divided by the Armoric hills [CÔTES-DU-NORD; BRETAGNE] into two slopes, one inclining to the English Channel, the other to the Bay of Biscay. It presents a great variety of hill and dale, heaths, moors, forests, ponds, and marshes, which are rendered productive

by drainage, or on the coast by banking out the sea. The soil, except in the marsh land, is shallow and light; the most fertile soils are in the neighbourhood of St.-Malo, Montfort, and Rennes, and in the marshes north of Dol. The coast, which extends between the embouchures of the Couesnon and the Rance, measures about 40 miles; it is washed by the fine Bay of Cancale; but access to it is much impeded by a great number of isolated rocks and islets. St.-Malo in the north and Redon in the south of the department, are the most important ports.

The department takes its name from the Ille and the Vilaine, the two principal rivers. The *Ille* rises near Combours, N. of the Armoric range, through a gap in which it runs S. and joins the Vilaine on the right bank at Rennes after a course of about 20 miles. Its waters supply the *Ille-et-Rance* Canal, which runs a considerable way along the Ille, and then, turning N.W., joins the Rance a little above Dinan. [CÔTES-DU-NORD.] The *Vilaine* rises a little W. of Ernée, in the department of Mayenne, and runs generally W. past Vitré as far as Rennes, 5 miles above which it becomes navigable. Having received the Ille at Rennes, its course is S.S.W. past Redon, whence to its mouth in the Bay of Biscay, below Roche-Bernard, it is a tidal river and navigable for vessels of 250 tons. Its whole length is 116 miles, 78 of which are navigable. On the right it receives the Canlache, the Chèvre, the Ille before mentioned, the Meu, and the Oust [MORBIHAN]; on the left its feeders are the Seiche, the Sennon, the Cher (which enters it on the borders of Loire-Inférieure), and the Don and the Isac, which flow from Loire-Inférieure, and are both navigable. The *Couesnon* rises E. of Fougères, and runs first W., then N. past Antrain, and enters the Bay of Cancale, below Pontorson, in the department of Manche. It is navigable at high water for barges from Antrain. The Rance is described under CÔTES-DU-NORD. The department contains 1,652,446 acres, and is traversed by eleven imperial, twelve departmental, and four military roads; the railroad from Paris to Brest passes Vitré and Rennes.

Products.—The farms are small, the largest not exceeding 75 acres, and many not more than 5. The soil is made to produce all kinds of breadstuffs, in quantity sufficient for the wants of the population. In the rich soils, wheat of excellent quality is raised; tobacco is grown near St.-Malo; rye, barley, oats, buckwheat, and mixed grain are produced in the middling and poorer soils. The cultivation of flax and hemp for the manufactures of the department is very extensive; the flax and hemp in the dressed state, as also the seeds, are important objects of commerce. The apple and the pear are very extensively cultivated for making cider and perry, the chief drinks of the population; the cider is strong enough to keep for two years, and is considered the best made in France. The grass land along the river bottoms is rich; and as the outlet on the heaths and moors is large, great numbers of cattle are reared, and excellent butter and cheese are made. The honey and wax of the department are also celebrated. There is little meadow land; of artificial grasses only clover is grown. Horses, in general of small breed, sheep, goats, poultry, and pigs of the large white breed are numerous. Game, including

wild boars, hares, rabbits, partridges, quails, woodcocks, &c., is abundant. The fisheries on the coast, which are actively plied, yield excellent oysters, soles, lobsters, turbot, skate, crabs, &c. The forests of the department contain fine timber: the prevailing kinds are oak and beech; next come chestnut, poplar, and birch. The cultivated land also presents the appearance of a forest, such is the number of apple trees planted in the fields, and of timber trees in the hedges that separate each field; but as these latter are regularly stripped of their branches to supply firewood, they are of little value as timber.

Several iron mines are worked; roofing and clay slate, white quartz for the glass factories, limestone, and granite are quarried; lead and copper ore is found. Mineral springs are numerous.

The most important manufactures are linen, sailcloth of the best quality, Russia duck, canvas, and shoe and morocco leather; felt and straw hats, sewing thread, thread stockings, ship cordage and ropes, fishing nets, hooks and lines, pottery, cotton and woollen yarn, are also made. There are, besides, several glass-making, tanning, and bleaching establishments, brandy distilleries, paper-mills, iron-forges and smelting furnaces, and flour-mills; in the towns on the coast shipbuilding is carried on to some extent. Salt is made in some of the marshes on the coast. The commerce is composed of the various articles named, and of groats, chestnuts, salt pork, hides, oak staves, firewood, &c. About 300 fairs are held in the year.

Climate.—The climate is damp, but temperate; much rain falls in winter; the prevailing winds are the west, north-west, and south-west; hurricanes are less frequent and less destructive than in some of the more western departments.

The condition of the peasantry is similar, but rather superior, to that of the peasantry of FINISTÈRE. The department contains many Druidical and Celtic remains, consisting of monoliths (menhirs), altar-tables (dolmen, kistvaen), cromlechs, and cairns.

Divisions and Chief Towns.—The department is divided into six arrondissements, which with their subdivisions and population are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1863.
Rennes, . .	10	78	144,804
Fougères, .	6	57	84,911
Montfort, .	5	46	60,305
St.-Malo, .	9	62	130,302
Vitré, . .	6	61	81,605
Redon, . .	7	46	83,003
Total, . .	43	350	584,930

Of the arrondissement of Rennes, and of the whole department, the capital is RENNES. *Hédé*, a small place of about 1000 inhabitants, on the road from Rennes to Dinan, is remarkable for the remains of its ancient castle, which was taken by Henry II. in 1168. *Janzé*, S.S.E. from Rennes, has 4471 inhabitants, who manufacture sailcloth, and deal largely in excellent poultry. *Liffré*, N.E. of Rennes, has a population of 2885. *Mordelles*, S.W. of

VOL. VII.

Rennes, on the left bank of the Meu, has mineral springs, and 2560 inhabitants.

In the arrondissement of Fougères the chief town is *Fougères*, which stands on a hill, at the intersection of five high roads, in the north-east of the department. It is one of the best built towns of the department, has wide, straight streets, a tribunal of first instance, a college, and 9470 inhabitants, who manufacture sailcloth, canvas, tape, flannel, lace, hats, bricks, leather, paper, and glass. There is a good commerce in these articles, and in corn, groats, butter, honey, cattle, &c. The castle of Fougères is a picturesque object, but a feeble defence, as it is commanded by the higher part of the town. In the forest of Fougères, within half a mile of the town, there are many Druidical remains. *Antrain*, N.W. of Fougères, on the left bank of the Couesnon, which here becomes navigable, has a population of 2262, and some manufactures of linen, coarse woollens, serge, and leather. *St.-Aubin-du-Cormier* stands on a steep hill, S.W. of Fougères, and has 2098 inhabitants. It owes its origin to a strong castle built by Pierre de Dreux, duke of Bretagne, in 1223, and is famous for the victory gained here by the Count de la Tremouille, the commander-in-chief for Charles VIII., over François II., duke of Bretagne, the prince of Orange, and the duke of Orleans, afterwards Louis XII. *Louvigné-du-Désert*, 9 miles N. from Fougères, had formerly a large establishment belonging to the Templars, whose church is now become the parish church. It has a population of 3675, and several tanyards.

In the arrondissement of Montfort the chief town, *Montfort-sur-Meu*, situated 10 miles W. from Rennes, on a hill above the confluence of the Meu and the Chailloux, has a tribunal of first instance, a college, and 2168 inhabitants. It is closed in by ramparts, flanked with towers, and encircled by a wide ditch. The town was formerly of much larger size. In the environs, which are very pretty, are the oak forests of Bresilien and Montfort, in the former of which are several Druidical remains; among others the tomb of the enchanter Merlin, so celebrated in Breton fables. *St.-Méen*, 10 miles W. from Montfort, has an ecclesiastical school, and 2304 inhabitants. *Montauban*, formerly the chief town of a county belonging to the dukes of Rohan, is 7 miles N.N.W. from Montfort, and has a population of 3082. *Plelan-le-Grand*, 12 miles S. by W. from Montfort, has 4138 inhabitants, who manufacture great quantities of sewing thread.

In the arrondissement of St.-Malo the chief town, *St.-Malo*, is built on the rocky isle of Aron, which communicates with the mainland by a causeway named Le Sillon, and defended from the violence of the waves by strong outworks. The town covers the whole island; it is surrounded by strong ramparts, which are flanked with towers and bastions, and form a fine promenade. The streets are narrow, but formed by high and in general well-built houses. There are four gate entrances, near one of which, called La Grande Porte, is a large reservoir, whence water is supplied to the fountains in the streets. The most remarkable building is the strong castle built by Anne, duchess of Bretagne, which forms part of the fortifications. The former cathedral is a very capacious church, built in the

Gothic style, and ornamented with several good marble statues. St.-Malo has tribunals of first instance and of commerce, a chamber of commerce and manufactures, a naval school of the first class, and 9330 inhabitants. The harbour lies S. of the town; it is capacious and safe, but the entrance to it is rendered intricate by a great number of islets and rocks which stud this part of the coast, and many of which are fortified. It is a tide harbour, protected by a strong pier, and lined with a broad quay, which runs just under the walls of the town; it is dry at low water, but large ships can enter, as the tide rises very high here, 49 feet at spring. A wet dock has been formed by throwing a strong granite wall across the head of the bay between the town and the suburb of *St.-Servan*; it contains an area of above 270 acres, and is entered by wide flood-gates, through which steamers and war frigates can pass. The roadstead of St.-Malo lies W. of the town, at the embouchure of the Rance: it is protected by seven forts, one of which, called *Conchée*, was constructed by Vauban. The manufactures of St.-Malo are hosiery, fishing-nets, ship pulleys and cordage, soap, fishing-hooks, &c. Shipbuilding is carried on, and there is a large tobacco factory. The imports consist of colonial produce, spices, flax, hemp, &c.; there is also a considerable trade in corn, fruit, wine, brandy, salt, linen, cider, butter, honey, fish, salt provisions, &c. The town has long been celebrated for its brave and skilful seamen. Vessels are fitted out for the foreign and coasting trade, and for the whale, cod, and mackerel fisheries. St.-Malo is much frequented as a bathing town. It was the birth-place of Jacques Cartier, the discoverer of Canada, and also of the illustrious Chateaubriand. The railroad from St.-Malo to Rennes was opened in 1864. *Boussac*, near Dol, is a small place, with 3029 inhabitants. *Cancale*, a small seaport on the western side of the Bay of Cancale, with 6352 inhabitants, is eight miles E. from St.-Malo. The principal part of the town stands on a height, above the bay of which it commands a fine view, and is well built. The other part, called *La-Houle*, is built on the shore, and is inhabited chiefly by fishermen, who take vast quantities of oysters and other fish in the bay for the supply of Paris and the towns in the interior. *Combours*, twenty miles S.S.E. from St.-Malo, is situated on a small lake, and has 5033 inhabitants. There is an old chateau, flanked with towers, in good preservation in the town. *Dol*, remarkable for its ancient cathedral, which is one of the handsomest churches in Bretagne, is fifteen miles S.E. from St.-Malo, and has 4191 inhabitants. It is surrounded by old walls and wide ditches, the remains of its ancient fortifications. The interior is irregularly built; the houses are constructed of dark granite with projecting gables; arcades seven or eight feet wide, supported on granite pillars, run along the streets. The town has a good corn market; there is also some trade in cider, hemp, flax, tobacco, cattle, &c. The neighbourhood of Dol is fertile; all the land between it and the sea northwards is drained marsh, protected from the sea by dykes. *Plaine-Fougères*, twenty-five miles from St.-Malo, has a population of 3201. *St.-Servan*, a well-built town and much frequented watering-place situated on the south side of the harbour of St.-Malo, of

which town it may be considered a suburb, has 12,709 inhabitants. The most remarkable structure is the isolated tower called *Solidor*, which is 60 feet high, and approached by a drawbridge. This tower is now used as a prison. Beer, ship cordage and biscuits, wine, brandy, &c., are the chief articles of trade; shipbuilding is carried on. It has an active trade with the East and West Indies. *Tinténiac*, on the Ille-et-Rance Canal, has 2149 inhabitants, who trade in corn, butter, poultry, &c.

In the arrondissement of Vitré, the chief town, *Vitré*, situated on the Cantache, 22 miles E. from Rennes, has a tribunal of first instance, an ecclesiastical school, and 8904 inhabitants. The town is large, but irregularly built; and its feudal fortifications, consisting of a castle, high ramparts flanked with machicolated towers, and surrounded by a deep ditch, give it a gloomy appearance. The church of Notre-Dame is the most remarkable structure in the town. Vitré has manufactures of thread stockings, serge, flannel, hats, casks, brandy, leather, and sailcloth, and trades in these articles, and in wine, linen, honey, wax, hides, cattle, and cantharides flies, which are found in the neighbourhood. The other towns are *Argentré*, which is a few miles S. of Vitré, and has 2242 inhabitants; *La-Guerche*, a town of 4678 inhabitants, which stands in a rich corn and grazing country, 11 miles S. from Vitré; it gives name to a neighbouring forest, and has manufactures of fine linen, leather, and nut oil, besides a good trade in butter, corn, flax, hemp, chestnuts, cattle, sheep, &c.; and *Rhetiers*, which is a few miles W. of La-Guerche, and has 3127 inhabitants.

Of the arrondissement of Redon the chief town, *Redon*, stands at the foot of a hill on the Vilaine, which here forms a good tide harbour, with a rise of from ten to thirteen feet at high water. The town, which is situated in the most southern angle of the department, at the junction of the two branches of the canal from Nantes to Brest, and at the southern extremity of the river and canal navigation that terminates to northwards in the harbour of St.-Malo, enjoys great advantages for trade, in addition to its connection with the Bay of Biscay by a navigable tide river. It is in general well built; the chief structures are the former abbey buildings, now used as a college, and the abbey church, the semicircular apse of which is considered a masterpiece. Redon has a tribunal of first instance, a college, and 5943 inhabitants, who carry on a considerable trade in colonial produce, wine, brandy, salt, butter, chestnuts, timber, hemp, oak staves, planks, masts, pitch and tar, slates quarried in the neighbourhood, sheet and bar iron, lead, resin, hides, linen, flax, canvas, &c. Vessels of 50 to 400 tons are built. The harbour of Redon, to which the French attach great importance, as in case of a war with England their trading vessels could enter here without exposing themselves in the Channel, was greatly improved in 1847. The other towns are—*Bain*, which stands on the great road from Rennes to Nantes, and has a population (with commune) of 4454, and some woollen manufactures; *Fougeray*, 16 miles N.E. from Redon, which has 5859 inhabitants; it had formerly a strong castle, of which only one high massive tower remains, and from which the English were driven by Du Guesclin in 1356; *Guichen*, which is 25 miles

N.N.E. from Redon, and has cold mineral springs, and 3696 inhabitants; *Maure*, 15 miles N. from Redon, which has a population of 4075, and an ancient castle taken by Henri IV. in 1597; and *Pipriac*, 12 miles N. from Redon, which has 3343 inhabitants.

The department forms the see of the bishop of Rennes, is included in the jurisdiction of the Cour Royale and University Academy of Rennes, and belongs to the sixteenth Military Division, of which Rennes is head quarters.

(*Dictionnaire de la France; Annuaire pour l'An 1866; Guide Classique du Voyageur en France*; Jephson, *Travels in Brittany*; Malte Brun and Lavallée, *Géographie Universelle*.)

ILLECEBRACEÆ, a small natural order of exogenous plants, chiefly consisting of herbaceous weeds, found in the temperate parts of the world. The species are often conspicuous, especially when dried, for their silvery stipules and shining calyxes, and are sometimes beautiful microscopic objects; but they are too small to be interesting in any other way, and are of no known use.

ILLEGITIMACY. [BASTARD.]

ILLICEBRUM, a genus of plants the type of the natural order *Illicebraceæ*. The only species is a small trailing shrub with opposite leaves, having scarios stipules at the base. *I. verticillatum*, Whorled rush-grass, is found in bogs and wet marshy places, chiefly in Cornwall and Devonshire.

ILLICIUM, a genus of plants now generally described as a separate family under the name of WINTERACEÆ. It is known as the Aniseseed-tree.

ILLINOIS, one of the United States of North America, is bounded S.E. by the river Ohio; E. by Lake Michigan and Indiana; N. by the parallel of 42° 30' N. lat.; W. by the Mississippi. It lies between 42° 30' and 37° N. lat., and between 87° 30' and 91° 25' W. long. The greatest length is about 380 miles, and breadth 310 miles. The entire area is 55,409 square miles, or about 35,500,000 acres. The inhabitants in 1860 numbered 1,711,951, of whom 7,628 were free coloured. The population has increased very rapidly, having been only 12,000 in 1810, and includes many Germans and Irish.

The Kaskaskia rises on the east side of the state, and, flowing to the S.W. for about 250 miles, falls into the Mississippi about 80 miles above the junction of the Ohio. The Illinois, the largest river in the state, rises near Lake Michigan, and flows W. and S.S.W. into the Mississippi, which it joins 20 miles above the Missouri. This large river takes the name of Illinois only from the confluence of the Plane River from the N.E., and the Kankakee from the E., both considerable streams, and navigable for boats. Thirty miles below their confluence the Fox River falls into the Illinois from the north: it rises in the Huron territory, and has a course of 200 miles S.S.W., more than half of which is in this state. The other principal tributaries of the Illinois are the Vermilion River from the S.E., the Mackinaw from the N.E., Spoon River from the N.W., and the Sangamon or Sangano from the E. The last is by much the largest of these tributaries. Rock river rises in the Huron territory, and entering the state of Illinois on its north boundary, crosses it in a S.W. course of about 200 miles to the Mississippi.

There is a range of low hills near the Ohio, and the western part of the state has an undulating surface; but with these exceptions, Illinois is one great plain, having a general slope to the south-west. Its soil consists of exceedingly fertile prairie and timbered land. The minerals are iron, copper, and lead, in the north-western angle of the state. Lead mines are worked, and are very rich. Coal is found in every part of Illinois. Limestones and sandstones are the usual rocks. The climate is much the same as that of Missouri, except that it is more humid, and in the swampy districts less healthy. The agricultural products of the state are maize, wheat, hemp, flour, tobacco, and fruits. Swine are reared in great numbers from the abundant mast of the forests. There are few manufactures in the state, except those of salt from salt-springs, and lead from the ore.

Illinois is divided into ninety-nine counties. The following are the principal towns, with the population of each in 1860:—

Springfield, near the centre of the state, is the seat of government. It has a state and courthouse, and will hereafter be famous in history as the burial-place of President Lincoln. *Alton* is 82 miles W. by S. from Springfield. Population, 7338. This town has one of the best landings on the river Mississippi. [CHICAGO.] *Galena*, 230 miles N. by W. from Springfield, is the chief town of the great lead districts of the Upper Mississippi, which is navigable here for the largest steamers. The town contains about 14,000 inhabitants, and sends out about 50,000,000 lbs. of lead annually. *Nauvoo* is 124 miles N.W. from Springfield, on the east bank of the Mississippi. A Mormon city, containing at one time 18,000 inhabitants, was founded here by the famous "Joe Smith" in 1840. He was killed by a mob in 1844, and their great temple was burned to the ground in 1848. The Mormons have since been expelled, and have settled at Utah; their place is now occupied by a colony of French socialists. *Quincy*, 104 miles S. from Springfield, is situated on a bluff, on the east bank of the Mississippi. Population in 1863, 13,632. It is visited by numerous steamers, and exports large quantities of pork.

In 1860 there were 2868 miles of railway in operation in the state, all the cities and towns being connected by lines.

Illinois sends nine members to Congress. It includes churches of all denominations, 4 colleges, 42 academies, and 10,238 primary schools; 14 incorporated, 9 theological seminaries, and 2 medical colleges. Nearly all the settlements have taken place since 1800. The constitution of the state was formed in 1847, and consists of 75 representatives elected for a period of two years, and 25 senators for four years. The governor and lieutenant-governor are, like the presidents of the United States, elected every four years.

This state is within the limits of the cession which Virginia made to the United States in 1787; but the first settlements made in it were by the Canadian French before 1763. It was governed, with Indiana, as a territory of the United States from 1800 to 1809. In 1809 they were made separate territorial governments, and in 1818 Illinois was admitted into the Union.

ILLUMINATI, the name of a secret order of society existing in Germany and some other parts of the Continent. Their professed object was to disseminate the purest principles of wisdom and virtue; but their real intention, it has been said, is the subversion of all existing governments and religions, in order to establish a perfect system of freedom and independence among mankind.

ILLYRIA, formerly a kingdom and province of the Austrian empire, now divided into the districts Carinthia, Carniola, and the Littoral, and lying between $44^{\circ} 43'$ and $47^{\circ} 5' N.$ lat., and $12^{\circ} 40'$ and $15^{\circ} 55' E.$ long. It was founded by a decree of Napoleon in 1809, and remained as a kingdom till the present arrangement into three provinces was adopted in 1849. The area of the country is about 11,000 square miles, and the population 1,300,000.

Face of the Country.—Illyria is on the whole a mountainous country, but the coasts are partly low and sandy, and partly marshy, especially towards the west. On the west the Bay of Trieste, and on the east that of Quarnero, run deep into the land, and form the peninsula of Istria, the extreme point of which is Capo-Promontore. In Villach and Clagenfurt the soil is good, and the valleys are in general fertile; but a great portion of the surface is rocky, and so high that the temperature is unfavourable to vegetation. Neustadt, Adelsberg, and Laybach consist of rock, marshes, and sandy flats, and are unfruitful. The coast has a dry limestone soil, and in many parts suffers from a scarcity of water, but the vegetation is very luxuriant. Three great chains of mountains, the Noric Alps in the north, the Julian and Carnic Alps in the centre and south, traverse the kingdom from west to east. All the mountains belonging to the chain of the Julian Alps are composed of primitive limestone, and are remarkable for the number of stalactitic caves they contain. [ADELSBERG.] The principal rivers are—the DRAVE, which is navigable, and flows for 120 miles through Villach and Clagenfurt; the SAVE, which becomes navigable at Laybach; the Isonzo, which rises in Mount Terglou (9300 feet high), the point of junction of the Carnic and the Julian Alps, and flowing S. enters the Gulf of Trieste, having received the Torre on the right, the Idria and the Wippach on the left bank; a few miles before reaching the gulf it divides into two branches, called the Isonzato and the Sdobba, which afterwards unite, inclosing between them the island of Morosina; the course of the Isonzo is important as having once formed the eastern limit of Italy towards Austria; and the *Quieto*, which enters the Adriatic through the harbour of Città-Nuova. Of the numerous lakes, the largest are—the Lake of Clagenfurt, 11 or 12 miles long, but narrow; the Ossiach Lake, 7 miles long; and the Mühlstaller Lake, $8\frac{1}{2}$ miles long, and from 2 to $3\frac{1}{2}$ miles wide; this is the deepest and most beautiful lake in Carinthia, and the surrounding scenery is highly picturesque.

The most remarkable lake in Carniola is that of Zirknitz, about 3 miles long and 2 wide, of which many wonderful stories are told, all originating in the fact that it is sometimes quite full, and at others dried up, or considerably reduced in size, and this without any regularity or regard to the season of

the year; sometimes it does not dry up for years together. This peculiar phenomenon is apparently dependent upon subterranean cavities. Carinthia is much more abundant in mineral waters than Carniola, but there are none that enjoy any remarkable celebrity.

Climate.—The climate of course varies in different parts. The lofty mountains, covered with snow, which either never melts or only in the height of summer, cause the air to be rather sharp and raw in Villach and Clagenfurt: the vine does not thrive here. Though there are some persons afflicted with goitre, the climate is on the whole healthy. It is much milder in Laybach, Adelsberg, and Neustadt, where the vine, chestnut, and maize flourish. Trieste has a hot climate; the vegetation is luxuriant, but there is a deficiency of water. In the western parts on the coast the air is rendered unhealthy by the exhalations from the lagunes.

Products.—Illyria abounds in mineral wealth. Besides quicksilver, it has copper of the finest quality, and yields excellent iron, lead, silver, cinnabar, alum, coals, marble, rock-crystal, porphyry, jasper, garnets, &c.

The vegetable products contain many rare Alpine plants, medicinal herbs, and roots; also wheat, rye, barley, oats, maize, buck-wheat, potatoes, pulse, some flax, hemp, and hops, garden vegetables, and fruit. The forests have been much thinned for the use of the iron-works, but there is still an abundance of pine, oak, and other timber. The horned cattle and the horses are in general small. The largest flocks of sheep are in the islands, especially in Veglia, which has likewise many horses. Swine and poultry abound everywhere. Of wild animals there are stags, deer, wild boars, chamois, foxes, &c. Bears and wolves are rare. The game consists of pheasants, bustards, partridges, snipes, and waterfowl. The tunny, mackerel, and anchovy fisheries on the Adriatic are very important. The most important manufactures are those of various articles in iron and steel. The commerce consists chiefly of the transit trade between Vienna and Trieste.

Chief Towns.—Laybach, the capital of Carniola, is situated in an extensive valley at the mouth of the navigable river Laybach, a feeder of the Save, which divides the city into two parts, connected by five bridges. Laybach has 21,000 inhabitants. It is a bishop's see, and has a fine cathedral, twelve other churches, a lyceum, a gymnasium, and many other excellent public institutions. The castle is situated on a commanding eminence. At a short distance to the north of the town there is a stone bridge of 11 arches, 540 paces in length, over the Save. It is on the line of railway from Vienna to Trieste. There are manufactures of porcelain, refined sugar, and linen fabrics; and an active transit trade exists between Germany and Trieste. Laybach was, on two occasions, for some months the residence of Sir Humphrey Davy, and the seat of the congress of 1820-21, which was for a time fatal to Italian liberty. Neustadt is beautifully situated on the river Gurr, a feeder of the Save; it is a very pretty, regularly built town, with three churches, a gymnasium, a Franciscan convent, and 1750 inhabitants. Adelsberg, only important from the remarkable grotto in its vicinity, is noticed under

ADELSBERG. *Idria*, famous for its quicksilver mines, is situated at the bottom of a narrow valley surrounded by high mountains, on the banks of the little river *Idria*, and has 4450 inhabitants, who subsist partly by lace-making and straw-plating; but the greater part are employed in the mines and in the quicksilver works and cinnabar factories in the neighbourhood. The entrance to the mine is nearly in the middle of the town, by a large iron gate, which opens to a horizontal passage leading to a flight of 757 steps cut in the limestone rock. The mine is worked in the service of the government, and is one of the most productive in the world. It employs upwards of 600 workmen; and from 3200 to 3500 cwt. of quicksilver are produced annually. The inhabitants of the town indicate by their pale countenances the pernicious atmosphere they inhale, impregnated by the vapours of the various preparations of mercury manufactured in the place. The whole district is said to be so affected that cattle cannot be reared, and neither fruit nor grain will ripen. Formerly criminals were deported to the mine as workmen, but now free labourers are employed, tempted by high wages. *Clagenfurt*, the chief town of Carinthia, is noticed under **CLAGENFURT**. *Villach*, another town of Carinthia, is situated on the Drave, in a beautiful country, which has been called the Inner Austrian Switzerland. The town, which was formerly much larger than it now is, has 2487 inhabitants. Villach is a place of some importance in a commercial point of view, as it stands at the junction of three great roads leading to Vienna, Venice, and Innspruck. Villach was the scene of one of the first great defeats sustained by the Turks, in 1492, in their attempt to reach the heart of Christendom. A few miles W. of Villach are the important lead mines of *Bleiberg*, so named from the little town of **BLEIBERG**, which has a population of 2255.

Trieste, the principal seaport of Austria, is described in the article **TRIESTE**. *Capo d'Istria*, a seaport on an island a few miles to the southward, but connected with the main shore by a causeway, was formerly a dependency of the Venetian republic. It has 5000 inhabitants, and produces large quantities of salt by the evaporation of the sea-water.

Ancient *Illyria* comprehended all the provinces on the east coast of the Adriatic, with the adjacent islands as far as Epirus, and was inhabited by a people called by the general name of the *Illyric* nations. *Illyria* also extended into the interior as far as the *Ister* (Danube) and the Alps which lie between Italy and Germany. Macedonia formed the eastern boundary.

IL OBEID. [KORDOFAN.]

ILSLEY, EAST. [BERKSHIRE.]

IMAGINATION denotes in its widest sense that faculty of the mind by which it produces at will thoughts, or ideas, as materials for every other mode of the mental activity. It is often employed in a narrow acceptance as synonymous with fancy, which properly is only a particular species of imagination combined with judgment. Still narrower is the faculty of imagination according to the definition of Dr. Reid, who confines it to a lively conception of the objects of sight, and makes imagination differ from conception only as a part from the whole. And

similarly Addison teaches, that 'the pleasures of imagination are such as arise from visible objects, since it is the sense of sight that furnishes the imagination with its ideas.' In its widest signification, however, imagination is coextensive with invention, furnishing the writer with whatever is most happy and appropriate in language, or vivid and forcible in thought. In the same manner it is the imagination that suggests to the scientific inquirer those bold conjectures of analogy or difference which lay open the secrets of nature, and multiply its usefulness to man. Indeed, to adopt the language of Dugald Stewart, 'all the objects of human knowledge supply materials for her forming hand; diversifying infinitely the work she produces, while the mode of her operation remains essentially uniform.'

It is in this illimitable activity that imagination differs from conception, which also is a reproductive faculty, but apparently a mere passive potentiality to bring forth certain given and particular ideas; while the former, when once awakened by the presentation of a single thought, produces out of its storehouse of ideas all the manifold variations of similar and dissimilar.

A disordered imagination exhibits itself under various forms or characters; as the fantastic, the fanatic, and the enthusiast.

On the particular character of the imagination depends much of the happiness or misery of the individual. Acting upon human hopes and fears, it assumes the name of sensibility, and by the bright or sombre images with which it fills the distant prospect of life, it affords a double relish to every enjoyment, or gives a keener edge to sorrow and misfortune.

IMAGO. A name given by Linnæus to the third state of insects, when they appear in their proper shape and colours, and undergo no further transformation.

IMAN, the title or designation of a Mohammedan priest, or one who has the care and superintendence of a mosque. It is sometimes applied, *par excellence*, to the founders of the four chief sects of the Mohammedan religion.

IMBECILITY. [INSANITY AND IDIOTCY.]

IMBROGLIO (Ital.), a term applied to the little burlesque theatrical pieces, the plot of which is perplexed or complicated. In literature it is also applied to the plot of a drama, or romance, which is involved in confusion.

IMBROS, an island of the Grecian Archipelago, belonging to Turkey. It is of an oval form, and its circumference about 40 miles. The surface is hilly and well wooded. The valleys produce corn, wine, oil, and cotton. The population consists of about 4000 Greeks, who inhabit four villages, the principal of which has a castle.

IMIRETIA. *[GEORGIA.]

IMMATERIALISM. [MATERIALISM.]

IMMORTALITY. [MATERIALISM.]

IMMORTALS, among the ancient Persians, a body of 10,000 soldiers, who constituted the personal guard of the sovereign, and were always of the same number. The same term was applied to the body-guard of the Roman emperors.

IMOLA. [RAVENNA.]

IMPACT (*in* and *pango*), the shock of two bodies, one or both of which are in motion: impact and

collision are the technical terms used in mechanics for the meeting of bodies in motion.

It is usual to treat the first principles of this subject by supposing the bodies in question to be spherical; because, if spheres of equal magnitudes be made to strike one another on a plane in the direction of a line joining their centres of gravity, and there be no friction on the plane, a motion of translation simply, without any rotatory motion, will take place. The conclusions deduced from the impact of such spheres, of equal or different weights, will hold good for bodies of any other form, provided there be no rotation, and the line joining their centres of gravity pass through the point of contact.

The consequence of friction taking place between the balls and plane is that the former acquire a rolling motion on the latter; and to this circumstance is owing many of the phenomena observed in games of billiards.

Let us now suppose the ball A to be impelled directly towards an immovable obstacle, such as an upright ledge at the end of the table. On striking this ledge the ball will, generally speaking, recoil more or less. Some substances will hardly give any recoil, while others will send the ball back with nearly the same velocity as that of its approach. At the moment of impact, the ball and obstacle compress one another, and the pressure continues until the reaction has destroyed all the velocity of the ball. If, then, there were no effort in the parts of the obstacle, nor in those of the ball, to recover their former position, the ball would remain at rest, close to the obstacle. If the recoil were complete, that is, if the parts of both bodies endeavoured to recover their position with a force equal to that which disturbed them, the recoil would rapidly but gradually [IMPULSE] create in the ball a velocity equal to that with which it approached. In the first case the bodies are said to be wholly inelastic, and in the second the elasticity is said to be perfect. But if only a fraction, e , of the velocity of approach be restored, then e is said to be the measure of the elasticity of the bodies. Perfect elasticity is usually represented by unity.

Now suppose the ball A (which is so small that its size may be neglected) to approach obliquely

towards the obstacles X Y, say in the direction C D. Let C D be the velocity or length moved over in one second. Then [COMPOSITION; VELOCITY] the velocity C D is equivalent to the two velocities C K and K D. The first is destroyed and then partially restored by the impact; the second remains unaltered, except by the friction at the moment of impact, which we do not consider. If, then, we take D L equal to K D, and draw L M perpendicular to X Y, and in length such a fraction of K C as e is of 1, the ball will move, after impact, with the velocities D L and L M, that is, with the velocity D M in the direction

D M. If the system were perfectly inelastic, the ball would proceed along D L; if perfectly elastic, M L would be equal to C K, and D M and C D equally inclined to X Y. If the size of the ball be taken into account, X Y must be supposed to be a line parallel to the obstacle, and distant from it by the radius of the ball. On the same principle may the motions resulting from the oblique impact of two elastic balls be determined.

It is proved in all treatises of elementary mechanics that, if two balls designated A and B (which letters represent their weights) move in the same direction with the velocities a and b , A being the hindmost and a the greater velocity; also if e , a proper fraction, represent the elasticity of each ball, we have, after the impact, the velocity of

$$A = \frac{Aa + Bb - eB(a - b)}{A + B} = u,$$

and the velocity of

$$B = \frac{Aa + Bb + eA(a - b)}{A + B} = v.$$

Subtracting the former from a , and b from the latter, we obtain the velocity lost by

$$A = (1 + e)(a - b) \frac{B}{A + B} = \alpha,$$

and the velocity gained by

$$B = (1 + e)(a - b) \frac{A}{A + B} = \beta;$$

hence the momentum lost by A and gained by

$$B = (1 + e)(a - b) \frac{AB}{A + B}.$$

Again, by subtraction, $v - u = e(a - b)$.

Lastly, from the above values of u and v we obtain

$$\begin{aligned} Au^2 + Bv^2 &= Aa^2 + Bb^2 - (1 - e^2)(a - b)^2 \frac{AB}{A + B} \\ &= Aa^2 + Bb^2 - \frac{1 - e}{1 + e} \{Aa^2 + Bb^2\}. \end{aligned}$$

The preceding formulæ will remain true when the bodies are moving in contrary directions, if, the direction of A's motion being called positive, b , or the velocity of B, be made negative. The signs of the formulæ will show in which direction the motion after impact takes place. Making $e = 0$ in the above formulæ, we have the corresponding formulæ for inelastic bodies; and, making $e = 1$, we get the formulæ for bodies whose elasticities are supposed to be perfect, the necessary attention being paid to the signs in all cases. Thus, when the momenta Aa and Bb are equal to one another, two inelastic bodies moving in opposite directions rest after impact; and, when $b = 0$, or B is at rest before impact, the

common velocity after impact becomes $\frac{Aa}{A + B}$.

If two perfectly elastic balls be equal in magnitude, the velocity of each after the impact is that which the other had before the impact, both in magnitude and direction.

In all cases perfectly elastic balls recede from

each other after impact with the same velocity with which they approached before impact; since, if $e = 1$, $v - u = a - b$. But in every other case the rate of recess after impact is the same proportion of the rate of approach before impact, which e is of 1.

The *vis viva* of a couple of perfectly elastic balls is the same before and after impact; in every other case it is less after impact than before.

In every case of impact, when the balls approach one another with uniform velocities, the centre of gravity of the balls moves uniformly, and in a straight line. After the impact, though the directions and velocity of the balls may have changed, yet their centre of gravity still continues to describe the same line, and with the same velocity as before. This proposition also is proved in all works on elementary mechanics.

IMPALE, in Heraldry, means the arranging of two coats of arms side by side in one shield. This is usually done by husband and wife, and by bishops, deans, heads of colleges, and knights-at-arms, who impale their own arms with the insignia of office.

IMPATIENS, a genus of plants so called from the sudden and elastic force with which they burst their capsules. One of the species is well known as a highly ornamental annual by the name of Balsam, whence the natural family to which it belongs has been called BALSAMINÆ. The genus is especially an East Indian one, though single species extend into Europe, Siberia, and North America.

IMPEACHMENT. [PARLIAMENT.]

IMPENETRABILITY, a name given to the property of matter, the existence of which is suggested when we see that any attempt to place one solid body in the part of space occupied by another is either resisted by, or its success preceded by the removal of, the latter; or, in other words, that no two bodies can at the same time occupy the same space.

In some cases the impenetrability of matter can only be taken in conjunction with the hypothesis of its porosity. Otherwise it might be successfully disputed. For instance, salt may be dissolved in water without increasing the bulk of the fluid; the (impenetrable?) matter is then penetrated, or else the matter of the fluid has interstices. But if any attempt be made to press the fluid into a smaller space, the impenetrability of the water will appear by its resistance to the pressing substance. Are we not then making a purely gratuitous introduction of words to supply explanations of phenomena? The answer to this difficulty and others of a similar kind which occur in attempting to define simple mechanical terms, is that the beginner must not receive them as explanations or as doctrines, but simply as statements of observed phenomena, or as terms which imply that explanation is wanted, and serve, till further elucidation, to enable us to recast the phenomena themselves and the universality of their existence. The notion of impenetrability is founded on the supposition that, when one body approaches another which is at rest, it must be in contact with it before the latter will move; but many circumstances render it highly probable that actual contact never takes place, and that when the bodies are within a certain small distance from one another repulsive forces begin

to be exerted between them: the resistance alluded to is apparently therefore dependent on repulsive forces of whose cause and modes of action nothing is known.

IMPERATOR. [EMPEROR.]

IMPERATORIA, a genus of plants belonging to the natural order *Umbelliferae*. *I. ostruthium* is a native of Europe and Newfoundland in damp meadows and woods. This species is the Masterwort of old English herbalists, and the root has been much celebrated as an antidote against poisons, a diuretic, and sudorific.

IMPERIAL CHAMBER. [AULIC COUNCIL.]

IMPERMEABILITY, the property which certain bodies possess of resisting the passage of other bodies through their substance; thus the pores of glass are so minute that no pressure has been able to force any fluid through them, whereas gold is permeable by water. Oil skin, or waterproof cloth, is impermeable to the passage of water, in consequence of the repulsion existing between the particles of oil and water.

IMPETIGO is a disease of the skin, which has been defined to be 'an eruption of yellow itching pustules, appearing in clusters and terminating in a yellow, thin, scaly crust.' It is commonly known in this country as the humid or running Tetter, and occurs on all parts of the body, though most frequently on the extremities.

IMPLEMENTS, AGRICULTURAL. The principal of these are noticed in separate articles. The term comprises all the implements used by the farmer in the cultivation of the land and the processes of in-gathering the produce. Those implements which first suggested themselves to supply man's wants, were doubtless the spade, fork, and hoe; when animals were reduced to the service of man ploughs and harrows appeared in their rude forms. The scythe and sickle have existed from remote antiquity; but grubbers, cultivators, drilling machines, thrashing, winnowing, and crushing instruments, are comparatively of modern date. Wonderful improvements have of late years been made in the application of machinery to agriculture, and steam-power now performs a large share of the labourer's work. For a full description of all the modern improvements, see the article AGRICULTURAL IMPLEMENTS, and Plates 1-10, Vol. I.

IMPORTATION AND EXPORTATION. The regulations which govern the bringing of merchandise into, and sending it from, the United Kingdom, are embodied in the Customs Consolidation Act, 16 & 17 Vict., c. 107, which came into operation August 20, 1853. This enactment would seem to have met nearly all the requirements of the mercantile community; for since it became law but slight amendments have been found necessary, and these are recorded in 18 & 19 Vict., c. 96; 22 & 23 Vict., c. 37; 23 Vict., c. 22; and 25 Vict., c. 22.

By the forty-second section of the Consolidated Act the precise time at which an importation of goods shall be deemed to have had effect, is held to be the time at which the ship had actually come within the limits of the port at which such ship shall in due course be reported and the goods be discharged; and if a question arise upon her arrival in respect of any charge or allowance upon such ship, exclusive of cargo, the time of arrival shall be that

when the report of such ship has been or ought to have been made. No goods are deemed to be imported from any particular place unless they be imported direct from such place, and shall have been there laden on board the importing ship, either as the first shipment of such goods, or after the same shall have been actually landed at such place.

IMPORTS AND EXPORTS are the various kinds of merchandise brought into and sent from a country. Until the latter part of the seventeenth century no opportunities existed for the collection of an authentic account of commercial statistics. Scattered notices of the nature and amount of our trade, at various periods, may be found interwoven with the narrative of historians, but the authority on which such statements generally rest is usually obscure. As to the money value attached to those imports and exports, we may safely conclude, especially in regard to imports, that it was derived from the assessment which regulated the system of poundage; an assessment which, though conventionally representing the marketable worth of the various descriptions of merchandise subject to a uniform percentage, was arbitrary in effect, and admitted of adjustments by which the assumed prices of particular commodities were either raised or lowered, so as to aggravate or lighten the pressure of the tax. Artifices of this kind were not inconsistent with the spirit of an age imperfectly civilized and ignorant of the true principles of commercial policy. More correct views, however, began to be entertained of the real interests of the country, and of the use to be derived from commercial statistics. One evidence of this change of feeling is afforded by the institution of the Board of Trade in 1670; another is to be found in the establishment of the office of Inspector General of Imports and Exports in 1697, whereby provision was made that an account should be kept of the trade carried on by England with each foreign country, and with each of the British settlements and possessions abroad, showing the goods imported and exported, methodically enumerated and classified; their quantities by weight, tale, or measure; and their equivalent in money, computed at certain official rates of valuation then first assigned.

The weak point of this scheme was the fixed character of the official rates of valuation by which the amounts of the imports and exports were henceforward estimated. Those rates, it is reasonable to presume, corresponded as nearly as possible with the actual prices of the several commodities at the time when they were established. The general results obtained by their use would, therefore, for some years approach pretty closely to the truth; but the difference between the computed 'official' value and the unascertained real value, whose place it supplied, was always growing wider, and as commerce and manufactures enlarged the sphere of their activity, the divergence became rapid. Had it affected all branches of commerce alike, the mischief would have been less serious; for although the amounts of the imports and exports would both have been falsified the proportion between them might have been correctly shown, and the progress or declension of the trade carried on with particular countries might also have been indicated with tolerable exactness: but this was by no means the case. Various causes

were in operation to set the 'official value' and the 'real value' at variance, and those causes affected different articles with a different measure of force and in different directions. The prices of agricultural produce increased with the number of the population and the influx of the precious metals. The prices of manufactured goods declined as the use of machinery was extended and the supply of raw materials from abroad grew more abundant. The spices of the East were cheapened in proportion as the improvement of navigation diminished the cost and risk of their transport to Europe. The timber of the Baltic rose in value as the home supply became scanty and buildings of every kind were multiplied. By these and by similar causes all traces of the original agreement between the official and the real value were nearly effaced, and the habit of regarding the former as identical with the latter at length was very generally abandoned.

But another notion had by degrees gained ground, that the official value, however unsuitably designated, being at least a fair representative of quantity, its fluctuations would furnish a true index of the forward or retrograde movements of our trade, and a just criterion of its comparative extent at different periods, irrespectively of the rise or fall of prices. The notion was, however, fallacious, and it is a matter of surprise that a fallacy so easily detected should have so long maintained its hold of the public mind.

The truth is, that the official value *was not* a fair representation of quantity, except in those cases in which the quantity itself might have been exhibited with equal facility, and in which, therefore, the employment of the substitute was at best superfluous. Being deduced from the quantity by a direct arithmetical process, it represented it faithfully when any article was taken singly, and not less faithfully, of course, when several articles were taken collectively, provided they were all entered under some uniform denomination of weight or measure, and all valued at the same rate; but beyond these limits, its relation to quantity became confused, incapable of being appreciated, and therefore practically null. The official value, however, might in one sense be said to be of indispensable use, even though that use was deceptive. In the absence of any record of the real value of the imports or exports, it furnished the means of collecting into one sum a multitude of articles dissimilar in kind and variously registered, by the hundred-weight, the gallon, the dozen, and the yard, which otherwise it would have been impossible to reduce into a total; thus it filled up blanks, and gave the accounts of the national commerce a semblance of completeness. It supplied an answer, though a delusive one, to questions such as these:—'What is the annual balance of our trade?' 'What proportion do our present importations from France bear to those of a period twenty or fifty years ago?'

The first partial improvement in this state of things took place in 1798, when to assist in defraying the expenses of the war, the 'convoy duty' was imposed on the exports of British produce and manufactures. This being rated *ad valorem*, it was provided, by the Act of Parliament under which it was levied, that the shippers of such merchandise should make a declaration of its actual value, and that a

false declaration should render the party liable to a penalty. Thus was laid the foundation of an authentic record of the real value of one great branch of our commerce. The utility of this enactment was soon perceived, and some years later, after certain goods had been exempted from the export duty, it was deemed expedient to pass a special act (53 Geo. III., c. 98) providing that in all cases the shippers of 'free goods' should be held liable to furnish a declaration of value. In 1842 the last remnant of the *ad valorem* export duty was swept away; but the declaration of value continues to be required on the exportation of all goods the produce or manufacture of the United Kingdom, and it constitutes the only source of information we possess on that point. That the establishment of a record of the real value of British exports would be followed by the institution of some corresponding registry of the real value of imports might have been expected; but many years passed before steps were taken to accomplish that object. In the year 1848, however, a plan, which had originated in the office of the inspector-general of imports and exports, was submitted for the approval of the Treasury by the commissioners of customs; but no decision was obtained upon it until the year 1854, when by Treasury minute dated 6th October, the said commissioners received instructions to carry out the necessary arrangements.

The scheme thus sanctioned was accordingly brought into operation without delay, and after ten years' experience it may be affirmed with confidence, that the end proposed has been fully accomplished.

It may be proper here briefly to explain how the real value of the imports into the United Kingdom is ascertained. 1stly, In the case of certain articles—of those, namely, in regard to which the tariff prescribes that their value (either with or without a

specification of quantity) shall be stated in the entry inwards at the custom house—it rests on the declaration of the importers. If the officer of customs should see sufficient reason to question its correctness, he is entitled to require further evidence on the point, or he may examine the goods. 2ndly, Upon returns of the *average prices* of the articles belonging to each class of imported merchandise which are obtained by the statistical office at the Custom House monthly, either directly from some of the leading merchants or brokers in the city of London, who furnish the information from a desire to assist an undertaking which they believe to be serviceable to the public, or else through the agency of three gentlemen specially qualified for the duty, who have been appointed by the Treasury to collect such prices in London, Liverpool, and Hull respectively.

The returns thus procured from different quarters are carefully examined; their deficiencies supplied, when other means fail, by reference to the most trustworthy of the prices current and market reports printed for general circulation; they are compared with each other, so far as they are susceptible of such comparison; where they differ the cause of difference is investigated; and when this process has been gone through for each successive month, mean averages are struck for each article, which are applicable to the kingdom at large in respect to the importations of the entire year. These resulting averages are not always *single*; in many instances the diversity of species or quality, and the consequent diversity of price, attaching to the similar products of various soils and climes, render it necessary to apply different rates to the importations from different countries. The manner in which the operation is effected is shown in the annexed Table, transcribed from a recent Parliamentary paper:—

TABLE SHOWING THE MANNER IN WHICH THE REAL VALUE OF IMPORTS IS COMPUTED IN THE OFFICE OF THE INSPECTOR GENERAL OF IMPORTS AND EXPORTS, CUSTOM HOUSE, LONDON.

account is of no use as showing their true value; but it possesses some interest as indicating the fluctuations in their quantity. Unfortunately, however, the means do not exist of giving the quantities of the various articles imported and exported at different periods during the last century. The tables published by Sir Charles Whitworth, Mr. Macpherson, and others, specify only the aggregate official values, without specifying the articles or their values of which such imports and exports consisted, the records having been destroyed by the burning down of the Custom House in the year 1814.

In the preceding tables we have, however, given as complete a view of the trade of this country with all parts of the world from 1725 down to 1864, both inclusive, as can be derived from existing means of information.

The preceding statistics record the real value of total imports from, and of total exports to, the various foreign countries and British possessions, from 1854 to 1864 inclusive.

The chief articles of import during the present century have comprised—coffee, tea, sugar, spirits, spices, tobacco, wine, corn, cotton, wool, drugs, silks, tallow, hides and skins, timber and wood. In the last fifteen years—cattle, provisions of all sorts, seeds of various kinds, gutta-percha, and a lengthy list of miscellaneous articles, have been imported to an extent far beyond that contemplated on the remission of the Customs duties thereon.

During the first half of last century, and previously, woollen manufactures formed the principal article of home produce exported from Great Britain; next in importance were hardware and cutlery, leather manufactures, linen, tin, lead, copper and brass manufactures, coal, earthenware, and articles of apparel. Corn also, down to the year 1770, formed a considerable item in the list of exports; since that period, however, the balance of the corn trade has been with few exceptions very decidedly on the side of importation. Cotton was of small moment as an article of export till after 1770; but subsequently the extension and improvement of cotton manufactures has been so enormous that the value of cotton stuffs and cotton yarn amount, at present, to more than one-third of the entire exports of British produce and manufactures. [COTTON MANUFACTURES.]

On taking a review of this important subject, one cannot fail to be struck with the marvellous increase which has taken place in the import and export trade of this country within the last few years, as the preceding tables abundantly testify. It is, however, unnecessary here to reproduce the statistics of the various commodities which have contributed to swell the totals to such enormous magnitudes, inasmuch as the import and export accounts for every staple are set forth under its proper designation. (For much of the preceding matter we are indebted to two Reports of the *Inspector-General of Imports and Exports*—Mr. Messenger—and to *Parliamentary papers for 1865*.)

IMPOST (*Imposta*, Ital.), the horizontal mouldings serving as a sort of cap or cornice to the piers of arches, and by which the archivolt or curved mouldings and fasciæ surrounding the arches themselves are supported. Imposts are contrary to the

genius of the Pointed style, but generally essential in Roman and Græco-Roman architecture.

IMPOUNDING. Occupiers of land have the right to seize and impound all cattle which may stray on their property. They may either detain them on their own premises, or take them to the nearest pound—that is, a public place inclosed for the purpose—till the amount of damage which they have committed is paid for. In either case they must feed and water the cattle (at the owner's expense), and they cannot impound them at all unless they are found actually straying on their land. In Scotland the power is called the pounding of strayed cattle.

IMPREGNATION (in Vegetable Physiology). Plants in their more perfect species are furnished with organs, by the mutual action of which they are multiplied, the matter contained in the one fertilizing that which belongs to the other, and the result being a young plant, or embryo, or vegetable foetus. In what way this occurs is still very obscure, although modern observation has thrown some light upon the subject.

In a perfect plant the anther contains a matter called pollen. The pollen is a congeries of excessively small hollow cases, having to the eye the appearance of fine dust. Each case contains a mucilaginous residuum, which at the proper time is discharged, and falls upon the open orifice of the pistil. This process appears necessary to the formation of the seed, and is called impregnation. [EMBRYO; STAMEN.]

IMPRESSION. [SEAMEN.]

IMPRIMATUR, a license to print a book, &c., which is granted by the licenser in those countries where censorship of the press is exercised in its rigour. The power of granting or withholding it was assumed by an act of the Long Parliament passed in 1647. After the Restoration the same power was assumed by King, Parliament, and Privy Council. This state of things continued till the Revolution.

IMPROPRIATION. [BENEFICE.]

IMPROVVISATORI are extempore versifiers upon any subject. This practice is of frequent occurrence in Italy. The improvvisatore delivers his verse, generally accompanied by a guitar, and with a sort of chanting cadence; and he spins out hundreds, nay, at times thousands of lines, with apparent ease: whole dramas have been thus delivered.

Some improvvisatori have been men of real information and poetical genius, and their compositions are consequently superior to the majority. Gianni, of Genoa, was made improvvisatore to Napoleon's court, and Sgricci, of Florence, became known throughout Europe by giving specimens of his art in the various capitals. Several ladies have distinguished themselves in the same art; they are styled improvvisatrici.

IMPULSE is that cause by which velocity is suddenly communicated to a body, apparently in an instant and without any perceptible gradations of motion.

Though the term impulse may be of convenient application to cases of motion in which velocities are changed very rapidly, it must be remembered that the idea of absolutely instantaneous change of velo-

city is in no degree less absurd than that of a point which is in two different positions at the same instant of time. Impulse, then, must be considered as pressure which, beginning from nothing, increases so rapidly with the time as to produce large effects in a small fraction of a second. [PRESSURE.]

INA, called also INAS, and IN, king of the West Saxons, and one of the kings of the heptarchy, was the son of Cenred, king of Wessex. He succeeded Ceadwalla, but how is not known, in 689, in the lifetime of his father Cenred; for a collection of laws which he published in the fifth year of his reign are stated in the introductory paragraph to have, been enacted with the advice of Cenred and other counsellors. These laws of Ina, to quote the summary of Dr. Lingard, 'regulated the administration of justice, fixed the legal compensation for crimes, checked the prevalence of hereditary feuds, placed the conquered Britons under the protection of the state, and exposed and punished the frauds which might be committed in the transfer of merchandise and the cultivation of land.' In 728 Ina resigned his crown, and retired to Rome, where he died before the end of the year.

INARCHING. [GRAFTING.]

INCA. [PERU.]

INCANDESCENCE. [IGNITION.]

INCANTATION, a term used to denote that mode of magic which was supposed to gain its efficacy from mysterious words uttered by the magi. Incantations were generally accompanied by the mixing of drugs and the performance of other magical rites, and the powers ascribed to them pass the bounds of modern credulity.

In a few remote regions even of our own country, incantations are still in use for curing dislocations and some diseases. In Chambers' 'Popular Rhymes of Scotland,' an account is given of the manner in which sprains are sought to be healed at the present day in the Shetland isles. The operation is thus described: 'When a person has received a sprain, it is customary to apply to an individual practised in casting the "wresting thread." This is a thread spun from black wool, on which are cast nine knots, and tied round a sprained leg or arm. During the time the operator is putting the thread round the affected limb, he says, but in such a tone of voice as not to be heard by the bystanders, nor even by the person operated upon—

Our Lord rade, His foal's foot slade;
Down he lighted, His foal's foot righted.
Bone to bone, Sinew to sinew,
Blood to blood, Flesh to flesh;
Heal, in name of the Father, Son, and Holy Ghost.'

INCENDIARY. [ARSON.]

INCENSE, perfumes exhaled by fire, and formerly used in honour of some god or goddess. Among the Jews the burning of incense was an act of worship, and appears to have been exclusively used for this purpose by them, as it was also by the Egyptians. By the Persians it was offered as a mark of honour to royalty.

In the Roman Catholic Church it has been used from time immemorial, and continues to be so in the service of high mass, in solemn consecrations, and in the burial of the dead. At the Reformation the Protestant clergymen abandoned the use of incense, as

unwarranted by Scripture; but it has recently been revived in one or two of the extreme 'high' churches. Incense, such as used in the present day, is usually made of gum olibanum, styrax, benzoin, and powdered cascarilla bark mixed together, placed in the censer in such a manner that when moved the ingredients fall on a hot plate, which immediately volatilizes them, and diffuses their odour through the building.

INCEST. During the Protectorate, in the year 1650, incest and adultery were made capital offences, but at the Restoration this law was not confirmed. Incest in England is now only punishable by the ecclesiastical courts, according to the rules of the canon law, which also determines what kind of sexual connection is incest. The notion of incest is founded solely upon the degree of consanguinity or affinity between the parties who have had the sexual connection. [MARRIAGE.]

INCHBALD, MRS. ELIZABETH, whose maiden name was Simpson, was the daughter of a farmer residing near Bury St. Edmund's. She was born in 1753. Losing her father in youth, she ran away at the age of sixteen to seek her fortune. After several adventures, she obtained a place in a country theatre, and soon married Mr. Inchbald, a respectable actor, much older than herself. Mr. and Mrs. Inchbald performed for four seasons in Edinburgh, and, after an engagement at York, went to France for a time. In 1779 Mr. Inchbald died at Leeds; and in the winter of 1780–81 Mrs. Inchbald played secondary parts at Covent Garden. She continued on the stage till 1789. She had begun to write dramatic pieces several years before her retirement from the stage; the first of these, a slight afterpiece, was successfully acted and printed in 1784; and from that time till 1805 she wrote plays in rapid succession, producing nineteen in all, one of which, 'Lovers' Vows,' is an adaptation from Kotzebue. They gained for her the means not only of supporting herself, but of making a handsome allowance to an invalid sister, and of saving a considerable sum. Her melodramatic comedy of 'Such Things Are' produced for her more than four hundred pounds: as much was the result of 'Wives as they Were and Maids as they Are;' and for 'Every One has His Fault,' the most strongly characterized of her plays, she received seven hundred pounds. Mrs. Inchbald's literary talents are best exhibited by her two novels, 'A Simple Story,' first published in 1791, and 'Nature and Art,' in 1796. She died on the 1st of August, 1821, at Kensington, leaving nearly 6000*l.* in legacies to her relatives and friends, to the Roman Catholic poor, and to the Covent Garden Theatrical Fund. She had written an account of her own life, for which she refused a thousand pounds; and, in obedience to her will, it was destroyed after her death: but her journal, kept regularly for many years, was preserved, and from it and her letters were written Mrs. Boaden's 'Memoirs of Mrs. Inchbald,' 1833.

INCHCOLM (*Insula Sanctæ Columbæ*), a small island in the Frith of Forth, near Edinburgh, and lying a short distance to the north-west of Granton harbour. It is noticed by Shakspeare as 'Saint Colm's Inch' (*Macbeth*, act. i., scene 2). The isle is not more than a third of a mile broad, and nearly three-quarters of a mile in length. St. Columba,

from whom it takes its name, is said to have long dwelt here. Alexander I. of Scotland was shipwrecked on it in 1223, and in gratitude founded an abbey on the island, traces of which, and of ecclesiastical buildings of a later date, are still to be seen. At the last census it was inhabited by seven persons. The word *inch*, it may be added, signifies 'island.'

INCIDENCE, ANGLE OF, the angle made by a straight line which passes through any point of a line or surface with the perpendicular to the tangent, or tangent plane of that line or surface, drawn through the point in question.

INCLINATION. The inclination of two lines is a phrase commonly used for the angle which they make with one another; thus, two lines which make a very small angle are said to be at a very small inclination to each other.

INCLINATION OF MAGNETIC NEEDLE.
[MAGNET, MAGNETISM.]

INCLINED PLANE, a plane surface making any angle with the horizon. A body placed on it is capable of being moved upwards along it with more facility than it can be raised in a vertical direction. The principle on which it constitutes a mechanical power was first introduced by Stevinus in the sixteenth century, and may be explained as follows:—Let AB represent a section of the plane, and G a section of the weight. Let GV represent the magnitude and direction of the weight, and draw GW and WV perpendicular and parallel to AB. Then [COMPOSITION] the pressure GV is equivalent to the two pressures GW and WV, of which the former is destroyed by the resistance of the plane, and the latter only acts to propel the heavy body down the plane. Now VW is to VG as BC is to AB; that is, a weight placed upon an

inclined plane is propelled down the plane by such a fraction of the whole pressure of the weight as the height of any section of the plane is of its length.

If, then, it were required to draw the heavy body G up the plane, any pressure exceeding WV would be sufficient for the purpose; and a pressure equal to WV, applied in the direction AB, would keep the weight at rest.

If a body be allowed to descend by gravity on an inclined plane, the force of descent is to the force downward, in a vertical direction, as WV to GV, or as AB to BC; that is, if θ be inclination BAC, and g represent the force of gravity vertically, as $g \sin \theta$ to g . Hence, if v represent the velocity on the plane and s the space descended from a state of rest in the time t , we have $v = g \sin \theta t$, $s = \frac{1}{2} g \sin \theta t^2$, and $v^2 = 2g \sin \theta s$. [ACCELERATED MOTION.]

From these formulæ it may be shown that the

VOL. VII.

velocity acquired by a body in descending from the top to the foot of a plane, whatever be its inclination, is the same as in falling vertically from the top to a horizontal plane passing through the foot.

If k be a fraction representing a portion of a weight W , to which the friction is equivalent; then, $W \cos \theta$ (represented by GW) being the pressure of W on the plane, $k W \cos \theta$ will represent the resistance caused by friction on the plane; and, if this be less than $W \sin \theta$, the impelling force on the plane, the weight will move downwards with an accelerating force $g (\sin \theta - k \cos \theta)$.

There are many remarkable properties connected with the motion or equilibrium of bodies on inclined planes; but the preceding are those which are most fundamental and most frequently required.

INCLOSURE. The term Inclosure is applied to the inclosing and partitioning of lands in England and Wales, which are comprehended under the general name of Commons or Common Lands. It is necessary to define the terms Commons and Commonable Lands. Commons or Common Lands are lands in a state of nature or waste, of which individuals have not the severalty. Commonable Lands are those lands which during a part of the year are in severalty, that is, occupied severally by individuals as their own, to the exclusion for the time of other people. [COMMONS.]

Common Rights, that is, rights of pasture and so forth on commons or waste lands, are described generally under COMMON, RIGHTS OF. Common pasture lands require an improved management. They are generally overstocked, partly in consequence of persons turning out more stock than they have a right to do, and partly by persons putting their stock on the common who have no right so to do.

In fact, for many years it was the opinion of competent judges that very great advantages would result from the general inclosure and allotment of commons, or part of them, for the purpose of cultivation, and in 1836 an Act (6 & 7 Will. IV. c. 115) was passed for facilitating the inclosure of open and arable fields in England and Wales. Previous to that time nearly every inclosure had to be effected by means of private Acts of Parliament, the expense of obtaining which and the trouble attendant in the carrying their provisions into effect, often prevented the inclosure being attempted.

In pursuance of the recommendation of a Committee of the House of Commons, which sat in 1844, an Act of Parliament was passed in 1845 (8 & 9 Vict. c. 118), the object of which is thus stated in the preamble:—'Whereas it is expedient to facilitate the inclosure and improvement of commons and other lands now subject to the rights of property which obstruct cultivation and the productive employment of labour, and to facilitate such exchanges of lands, and such divisions of lands intermixed or divided into inconvenient parcels, as may be beneficial to the respective owners; and it is also expedient to provide remedies for the defective or incomplete execution, and for the non-execution of powers created by general and local acts of inclosure, and to authorize the renewal of such powers in certain cases,' &c.

The principal provisions of this Act are, that no

A A

lands within fifteen miles of London, or within certain distances of other towns, which distances vary according to the population, shall be inclosed without the previous authority of Parliament in each particular case, nor were any town or village greens to be inclosed at all. The 30th section also provides that the commissioners to be appointed under the Act might set apart an allotment for the purposes of exercise and recreation for the inhabitants of any neighbourhood, and the 108th section makes regulations as to 'the allotment which, upon any inclosure under this Act, shall be made for the labouring poor.' Sections 147 and 148 provide for the exchange of lands not subject to be included under the Act, or subject to be inclosed, as to which no proceedings for an inclosure shall be pending, and for the division of intermixed land under the same circumstances.

In accordance with this Act, two commissioners, with a secretary, were appointed, under whose management its provisions have been, and are still being, extensively carried into operation. The commissioners make yearly reports to Parliament of the proceedings which have taken place, and Acts are passed almost every year confirming the inclosures submitted by the commissioners for approval. By the 22 & 23 Vict. c. 43, the Inclosure Acts were further amended and extended. The main object of the Act is to protect the lord of the manor's rights in mines, minerals, stone, or other substrata under the land to be inclosed, and for the purpose of providing compensation. Directions are also contained as to the assessment of damages. In their twentieth annual report, presented in 1865, the Inclosure commissioners state that since the passing of the Act the number of applications of all kinds has been 4658, and the whole acreage of inclosures confirmed was 454,437, while the acreage of those in progress amounted to 250,313 acres.

During the last seven years the number of applications and extent of inclosures have been equal to those of the previous thirteen, which seems to indicate that as the Act becomes better known its provisions are found to be well adapted to remedy the evils stated in the evidence before the select committee, and there can be no doubt that agriculture has been greatly improved, the productiveness of the land increased, and additional employment given to labour by this judicious and important piece of legislation.

INCOMBUSTIBLE FABRICS. Owing to the

great number of deaths which of late years have resulted from ignition of the clothing of women and children, many experiments have been made with the view of rendering linen, calico, and muslin garments incombustible. Many chemical preparations possess this property; but the two most recommended as being cheap, easily applied, and not liable to injure the colour or the material, are sulphate of ammonia and tungstate of soda. Of the first, a solution containing 7 per cent. of the crystalline salt is a perfect preservative; of the latter, a proportion of four ounces of tungstate of soda to one drachm of phosphate of soda, dissolved in a pint of water, will be found efficacious. The fabric should be dipped in the solution, or wetted all over with it, before ironing it. So simple a precaution ought to be universally adopted.

INCOME TAX. All persons in the United Kingdom whose incomes are over 100*l.* per annum—whether derived from property or labour—are liable to income tax. The amount has varied from time to time, the present (March, 1866) rate being 4*d.* in the *£.*—the lowest ever known. Persons whose incomes are under 200*l.* per annum are also allowed to deduct 60*l.* from the net amount, and pay only on the remainder. Income tax was first levied by Pitt, and revived by the late Sir Robert Peel in 1842, since which date it has regularly continued, and has always formed a marked feature in the budgets of Mr. Gladstone. Great difference of opinion prevails as to the fairness and public policy of the tax, the strongest arguments against it being its inquisitorial character, and its making no difference between professional and property incomes. The mode of collection is also much objected to; and if it is to be retained as a permanent tax there can be no doubt that the present district assessors—who often have to assess such persons as their rivals in business on the one hand, and their immediate friends on the other—should be replaced by the officers of the Inland Revenue, who could have no beneficial interest in knowing the incomes of persons amongst whom they may be placed.

The amount of income charged with income-tax in the United Kingdom in the year ending the 5th April, 1864, was 326,775,501*l.*—namely, 276,514,250*l.* in England, 27,137,918*l.* in Scotland, and 23,123,333*l.* in Ireland.

The following table gives the rate of income tax and the amount of revenue derived from it for the seven years ending March 31, 1865:—

	1859.	1860.	1861.	1862.	1863.	1864.	1865.
	Rate. 5 <i>d.</i> in the <i>£.</i> on all incomes.	Rate. 9 <i>d.</i> in the <i>£.</i> over 150 <i>l.</i> 6½ <i>d.</i> between 100 <i>l.</i> and 150 <i>l.</i>	Rate. 10 <i>d.</i> in the <i>£.</i> over 150 <i>l.</i> 7 <i>d.</i> between 100 <i>l.</i> and 150 <i>l.</i>	Rate. 9 <i>d.</i> in the <i>£.</i> over 150 <i>l.</i> 6 <i>d.</i> between 100 <i>l.</i> and 150 <i>l.</i>	Rate. Same as in 1862.	Rate. 7 <i>d.</i> in the <i>£.</i> on all incomes, but 60 <i>l.</i> allowance as those under 200 <i>l.</i>	Rate. 6 <i>d.</i> in the <i>£.</i> and the same allowance as 1864.
SCHEDULE.

Ireland was altogether exempted from payment of any income-tax until 1853, and there have been several arrangements to relieve that country from its burthen, as compared with Great Britain. For example, the amount of Schedules A and B has been assessed at the net value of lands, tenements, &c., exclusive of repairs and other charges under the Poor-law valuation, whereas this deduction has not been made from the assessments in Great Britain. Ireland and Scotland, moreover, are taxed at *one-third* of the total assessment under Schedule B, instead of *one-half* as in England and Wales.

From 1842 to 1853 incomes under £150 were exempt from income-tax.

INCOMMENSURABLES, THEORY OF. The application of arithmetic to any science of concrete magnitude supposes a certain magnitude to be taken as unity, and all other magnitudes to be expressed by the number of times or parts of times which they contain this unit. Such an application therefore requires the assumption of this proposition, that all magnitudes are either fractions or multiples, or compounded of fractions and multiples, of any magnitude that may be named. This proposition is not true; for instance, if the sides of a square be called 1, no number nor fraction whatsoever will exactly represent the diagonal. But it may be made as nearly true as we please: for instance, we may find a line as nearly equal to the diagonal as we please, which shall be a definite arithmetical fraction of the side. Quantities which are so related that, when one is capable of being represented in terms of a certain unit the other is not, are called *incommensurables*. The reason is as follows:—Any two magnitudes which have a common measure can be arithmetically represented by the same unit: for, if A and B have the common measure M, and if this measure be contained 7 times in A and 10 times in B, then it is evident that, by taking M as the unit, A is represented by 7, and B by 10. If, then, there be two magnitudes which cannot be represented by means of the same unit, they cannot have any common measure, and are therefore *incommensurable*.

The difficulty thus inherent in the application of arithmetic to concrete magnitude does not occur in practice, because no case can arise in which it is necessary to retain a magnitude so closely that no alteration, however small, can be permitted. But in exact reasoning, where any error, however small, is to be avoided, it is obvious that the arithmetic of commensurable magnitudes, and the arithmetic (if there be such a thing) of incommensurable magnitudes, must not be confounded. The difficulty was overcome by Euclid, in his doctrine of proportion, so completely and effectually, that nothing has been added to his solution of it except unsuccessful attempts to evade it. Those who avoid the fifth book of Euclid generally substitute either the tacit assumption that all magnitudes are commensurable, which is not true, or some metaphysical play upon words, which a person who feels the rigour of Euclid places on the same shelf with nature's horror of a vacuum, and other explanations of the same kind.

INCREMENT AND DECREMENT. When two quantities are considered together, one of which is greater or less than the second, the latter is said to be the former with an increment or decrement. In

the older English writings the calculus of differences is called the method of increments.

INCUBATION. [POULTRY.]

INCUMBENT. [BENEFICE.]

INCUMBERED ESTATES COURT. [IRELAND.]

INDEFINITE means 'not given or defined in magnitude.' Thus a definite straight line is that of which the extremities are known; an indefinite straight line is one of which the direction is given, and which may be supposed to have any length, or which can be lengthened, if necessary, without contravening any of the conditions of the problem. Thus Euclid, in the first book, constructs an equilateral triangle upon a definite straight line, and shows how to draw two lines making with one another the same angle as that made by two given definite straight lines.

There is, however, a reprehensible use of the word indefinite which is found in many mathematical works; namely, the employment of it to avoid the odium which attaches to the word infinite. Thus we hear of making a magnitude indefinitely great, of an indefinitely small are being equal to its chord, of the circle being a polygon of an indefinitely great number of sides. In all cases it would be better, with a proper definition, to use the word infinite at once.

A want of proper distinction between definite and indefinite sometimes leads to confusion. For instance, it is said that, if a straight line be halved, if its half be then halved, and if fresh portions be continually taken, each of which is the half of the preceding, the result will at last become less than 'any line which can be named.' This is not true if the line which is to be named be indefinite; that is, if we may at any part of the process make it as small as we please: for it is obvious that, whatever a line may be, a smaller line can be named. But it is true of a definite line, made definite, or given in length, at the beginning of the process. Name any line, however small, but such as you name it let it remain; then by continually halving any other line, however great, you must at last arrive at a line which is less than the length you named. The phraseology of a line 'less than any line which can be named,' has often caused a difficulty by not specifying the time at which it is to be named. The language used by Euclid himself is as follows (book x. prop. 1), and is free from the ambiguity in question: 'Two unequal magnitudes being given, if from the greater be taken away its half, and from what is left its half, and if this be done continually, a magnitude will at last be found which is less than the lesser of the two given magnitudes.'

INDEMNITY, ACT OF, an annual act passed to indemnify persons from penalties incurred by the omission of certain acts, such as taking the oaths, delivering qualifications, &c.

INDENTURE. When a deed was made by more than one party, there used to be as many copies as there were parts of it, and each part was cut or indented (formerly in acute angles, *instar dentium*, like the teeth of a saw, but at present in a waving line) on the top or side, to tally or correspond with the other—which deed so made was called an indenture. The term is now generally applied to an

agreement between an apprentice and his master. [DEED.]

INDEPENDENTS, the name of a denomination of English Protestant Dissenters. They are distinguished from Presbyterians by being opposed to any union or government of the church, and by regarding each congregation of faithful men as independent of every other, and competent to its own government without any interference from presbyteries, bishops, or from the state itself; this is the pure principle of English Independency. Macaulay describes the opinions of its founders in forcible language. 'They conceived,' he says, 'that every Christian congregation had, under Christ, supreme jurisdiction in things spiritual; that appeals to provincial and national synods were scarcely less unscriptural than appeals to the Court of Arches, or to the Vatican; and that Popery, Prelacy, and Presbyterianism were merely three forms of one great apostasy.'

Robert Brown, a clergyman of the reign of Elizabeth, is generally reputed to be the first person in England who acted upon these opinions. After he had given no small trouble to the authorities in the church, he was presented to the living of Achurch, in Northamptonshire. He, however, soon began to attack the order and discipline of the Established Church, and formed a distinct church on democratic principles at Norwich. His hasty temper often led him into trouble, and he closed a long and very troubled life in jail at Northampton in 1630. His followers were at first called Brownists, but they may fairly be identified with the Independents.

During the Commonwealth, the Independents were active in preventing the establishment of a Presbyterian church in England. Foremost among them was Cromwell. In 1662 the Act of Uniformity was passed, the object of which was to exclude from the ministerial office in the Church of England divines of either the Independent or Presbyterian opinions. The effect of it was, that about 2000 ministers retired from the places they held in the church. These are the ministers whom the Dissenters refer to when they speak of 'the illustrious two thousand,' or 'the Bartholomew Worthies,' because the act came into operation on St. Bartholomew's day, August 24th, and whose ejection was celebrated by the Bicentenary Movement of 1862. During the reign of Charles II. every effort was made to prevent the ejected clergy from continuing to exercise their ministry, but it was all in vain, and the Revolution of 1688 freed the Dissenters from the penalties in the way of fine and imprisonment which were imposed upon them; one of the first acts of the new government being to grant toleration to them, that is, to allow them to open chapels, and to conduct the services under the protection of law.

The 'Act of Toleration' was passed in 1689, and for the seventy years succeeding that date the Independent denomination (as indeed was the case with the whole body of Dissenters) decreased, and it would probably have become extinct but for the extraordinary revival of religious zeal, created especially by the Wesleys and Whitefield. Under this influence a large number of persons were led to join themselves to the Wesleyan or the Whitefieldian Methodists, the latter since better known as the

Countess of Huntingdon's Connection; but there were many who declined to unite themselves with either of these bodies, and joined the old Independents. By this accession the latter became the largest dissenting body in England except the Wesleyans, and so continue to the present day.

Early in the eighteenth century an agreement was come to between the Independents, Baptists, and Presbyterians, who formed themselves into a united body, under the title of the Three Denominations. They were for a long time in the habit of consulting together for general welfare, but of late years this union has been disturbed in consequence of the withdrawal of the Presbyterians—most of them having become Unitarians.

The Independents have numerous chapels in London and in various parts of the country, with many very popular ministers. They have also several institutions for the education of their ministers. They still maintain the principle of Independency, and are on this account often called Congregationalists—each congregation forming a separate church. They are in general strongly opposed to the principle of a state establishment, whether Presbyterian or Episcopal, and in doctrine vary from the high Calvinism of the Savoy Confession, which exhibits the doctrines held by the Independents of the time of the Commonwealth, to the most moderate form of Anglican orthodoxy.

Independency was introduced into Scotland at the time of the Commonwealth, but did not make much progress till 1730. There are now in that country upwards of 200 chapels, with accommodation for about 100,000 persons.

In the United States the Independents are very numerous and influential. They possess more than 3000 places of worship and about 300,000 members.

The *Congregational Year Book* for 1866 contains the following general summary of statistics of the Independent denomination compared with those of 1864:—

CONGREGATIONAL CHURCHES.

	1864.	1865.
In Great Britain, Ireland, and the Islands of the British Seas,	2768	2785
In the American colonies, . . .	117	117
In the Australian colonies, . . .	124	142
In foreign lands, ...	217	237
	3226	3281
Free Churches (Independent) in foreign lands, ...	128	229

CONGREGATIONAL MINISTERS.

In England and Wales, . . .	2139	2175
In Scotland, ...	97	106
In Ireland, ...	26	26
In the colonies, ...	215	226
In foreign lands, ...	176	179
	2653	2712
Students in theological colleges, &c.,	425	350
Students under private instruction,	30	74
Missionary students, ...	—	20
	455	444

CHAPELS OPENED IN 1865.

New, rebuilt, and enlarged, ...	110
Foundations of new chapels laid, ...	43
New schools, ...	14
	167
New churches formed, ...	14

The number of Congregational chapels in the metropolitan postal district is given at 220; of pastors, 178; of ministers without pastoral charges, 94.

(The best books to consult on English Independency are—Dr. Vaughan's *History of English Nonconformity*, London, 1862; Fletcher's *History of Independency*, London, 1862; and May's *History of the Puritans*.)

INDETERMINATE, a word which is mostly applied in mathematics, not to the character of a magnitude, but a problem. A question is said to be indeterminate when it admits of an infinite number of solutions.

INDEX EXPURGATORIUS, or INDEX LIBRORUM PROHIBITORUM is a catalogue of books, the reading of which is prohibited by papal authority to all Roman Catholics. The earliest known instance of this authority being exercised, is the prohibition of the writings of Arius. From that time and during the middle ages up to the present century, there has been a periodical publication of the Index, sometimes by sole order of the pope, at others by the councils. In the intervals between the editions, the decrees by which further additions are made to the list of prohibited books are made public at Rome, and circulated in the various countries. The books which are absolutely prohibited are all the writings of the founders of heresies, all immoral books, all books of heretical authorship on doctrinal subjects, all heretical versions of the Bible, and all books containing statements or doctrines prejudicial to the Roman Catholic religion. Among the well-known works that are put under the ban in the last edition of the Index, are Goldsmith's 'History of England,' Kant's 'Essay on Pure Reason,' Whately's 'Logic,' and Mill's 'Political Economy.' It also contains the names of Gibbon, Robertson, Hallam, Locke, Bacon, Milton, Addison, and Dante.

INDIA, BRITISH. In the article EAST INDIA COMPANY we have traced the rise and progress of the British rule in India; in that of DELHI, the mutiny of 1857 is more particularly noticed; and under HINDUSTAN will be found a general description of the physical geography of the whole country, its products, inhabitants, religion, ancient history, &c. In this article we shall, therefore, confine ourselves to the political geography of British India.

Area and Population.—The total area and population of British India are as follows, according to the latest returns:—

Presidencies.	Area in English sq. miles.	Pop.
Governor-General's district,	170,330	14,165,161
Bengal, ...	280,200	41,498,608
Madras, ...	128,550	23,127,855
Bombay, ...	137,743	11,937,512
Punjab, ...	100,406	14,794,611
North-west provinces, ...	116,493	30,110,497

Total, ... 933,722 135,634,244

The above numbers of the population are but the result of estimates, as an accurate enumeration has never been made—and, probably, cannot be made—owing to religious prejudices, and the peculiar mode of life of the natives of India.

In addition to the above presidencies, there are a large number of territories under the immediate control of the government of India, and states ruled by native princes and chiefs, but under the political supremacy and protection of the British government, so that the entire area of the whole Indian empire may fairly be said to be more than 1,500,000 square miles, and the population close upon 200,000,000. Every state of importance is described in a separate article.

The English population in India amounted, according to the returns made by the several governments, to only 125,945 persons in 1861. Of this number, 84,083 went to compose the British officers and men of the Indian army; while 22,556 consisted of men and boys in civil life, including the civilians in the public service; the remaining 19,306 being females.

Constitution and Government.—The present form of government of the Indian empire is established by the Act 21 & 22 Vict., c. 106, called 'An Act for the better Government of India,' sanctioned August 2, 1858. By the terms of this Act, all the territories previously under the government of the East India Company are vested in her Majesty, and all its powers are exercised in her name; all territorial and other revenues and all tributes and other payments are likewise received in her name, and disposed of for the purposes of the government of India alone, subject to the provisions of the Act. One of her Majesty's principal secretaries of state, called the secretary of state for India, is invested with all the powers hitherto exercised by the Company or by the Board of Control, and all warrants and orders under her Majesty's sign-manual must be countersigned by the same.

The executive authority in India is vested in a governor-general or viceroy, appointed by the Crown, and acting under the orders of the secretary of state for India.

The administration of the Indian empire is intrusted by the charter of August 2, 1858, to a council of state for India. The council consists of fifteen members, of whom seven are elected by the court of directors from their own body, and eight are nominated by the Crown. Vacancies in the council, if among those nominated, are filled up by her Majesty, and if among the elected, by an election by the other members of the council; but the major part of the council must be of persons who have served or resided ten years in India, and not have left India more than ten years previous to the date of their appointment; and no person not so qualified can be elected or appointed, unless nine of the continuing members be so qualified. The office is held during good behaviour; but a member may be removed upon an address from both Houses of Parliament. No member is to sit or vote in Parliament. The salary of each is fixed at 1200*l.* a year, payable, together with that of the secretary of state (5000*l.*) out of the revenues of India.

The duties of the council are, under the direction

of the secretary of state, to conduct the business transacted in the United Kingdom in relation to the government of and the correspondence with India; but every order sent to India must be signed by the secretary, and all despatches from governments and presidencies in India must be addressed to him. The secretary has to divide the council into committees, to direct what departments shall be under such committees respectively, and to regulate the transaction of business. He is to be president of the council, and has to appoint from time to time a vice-president. Both the president and vice-president lose office with the cabinet, of which the former is a member. The meetings of the council are to be held when and as the secretary shall direct; but at least one meeting must be held every week, at which not less than five members shall be present.

The government in India is exercised by a 'supreme council,' sitting at Calcutta, and consisting of five ordinary and from six to ten extraordinary members, presided over by the governor-general. The ministry, divided into the departments of foreign affairs, finances, the interior, military administration, and public works, form part of the supreme council. The appointment of the ministers, the members of the council, and the executive governors and lieutenant-governors of the various territories and provinces of the empire rests with the governor-general, who holds the highest office in the world filled by an uncrowned head, and who is appointed by the Crown for a term of about six years, with a salary of 25,000*l.* per annum, independently of a palace and establishment at Calcutta, and a country residence at Barrackpore.

The governors of Madras, Bombay, the north-west provinces, and the Punjab may also appoint a legislative council of from four to eight members; but the assent of the governor-general is required to render the measures passed by them valid, and they are further subject to the veto of the Crown.

The 'Covenanted Civil Service' is composed of Europeans, who conduct the general administration of British India, and whose salaries vary from 300*l.* to 8000*l.* per annum. It consists of nearly one thousand members. The staff is recruited from successful candidates at open competitive examinations, instituted for the purpose in England.

In the 'Uncovenanted Civil Service' the appointments are made by the authorities in India. It is composed of Europeans, Eurasians (the class sprung from native mothers by European fathers), and natives, with salaries of from 12*l.* to 3000*l.* per annum. It consists of nearly 7000 members, of whom about 2500 are natives.

Army.—The army of the old East India Company consisted of both natives and Europeans—the former, however, largely preponderating. The officers and non-commissioned officers were sent out from England, and the service afforded many opportunities for making rapid fortunes. The ranks were filled by enlistment; the company never compelled the natives to become soldiers, as the pay was always sufficient to secure the number required. The periods of leave of absence were liberal; and, after a much shorter period of service than in the English army, they were granted a pension sufficient to enable them to live in comfort for the remainder of

their days. Just previous to the mutiny the East India army consisted of about 24,000 royal troops (lent to and paid for by the Company), 18,000 of the Company's own European troops, 180,000 native regulars, 60,000 native irregular horse, and 40,000 contingents furnished by the native princes, making altogether about 320,000 men. Besides this force there were native armies belonging to the independent and semi-dependent princes—most of the latter being virtually under the control of the Company. As is but too well known, the Bengal portion of the Company's army was almost entirely broken up in the mutiny of 1857. Since the government of India was transferred to the Crown, the military service in that country has undergone a thorough re-organization, and there are now only 130,000 native troops in the whole empire. Many of these consist of Sikh regiments which behaved well during the crisis. The distribution of this force, according to the latest advices, was as follows:—Bengal, 71,175; Madras, 33,796; and Bombay, 25,360: total, 130,331. The British forces in India have, of course, been much increased, to compensate in some measure for the decrease of the native troops. They form part of the Queen's army generally, but their cost is defrayed out of the Indian, not the English, revenues. According to the army estimates, the European force was as follows in 1865-66:—

	Officers, mis'd Officers.	Non-com- and File.	Rank and File.	All Ranks.
Royal Horse Artillery, 201	249	2,680	3,130	
Cavalry of the Line, 352	575	5,082	6,009	
Royal Artillery, . 689	872	9,210	10,771	
Royal Engineers, . 336	—	—	336	
Infantry of the Line, 2,067	3,681	45,050	50,798	
Total, . . . 3,645	5,377	62,022	71,044	

The total cost of the army to the government of India is nearly 14,000,000*l.* per annum.

The *Indian Police* now forms a very important and useful force, and is to a great extent taking the place of the old native army. It has recently been remodelled on one uniform system, with a central organization in each presidency. It consists altogether of nearly 150,000 men of different races, and is chiefly officered by Europeans.

There is now no separate *Navy* for India, but a pilot service is still maintained.

Administration of Justice.—No code of civil or criminal law for India generally has yet been promulgated, but in the three presidential cities English laws and trial by jury have long been in force. In 1861 the supreme court at Calcutta and the Sudder Mofussil, or county courts, were abolished, and high courts of judicature were established in each presidency, and in the north-west provinces, under the control of a chief-justice, and as many other judges, not exceeding fifteen, as her Majesty may appoint. These high courts are to exercise civil, criminal, admiralty, testamentary, intestate, and matrimonial jurisdiction, original and appellate, by single judges or by division courts; so that now the verdicts of the inferior courts may be submitted to men of high legal knowledge.

Revenue, Expenditure, and Debt.—According to

the Act of 1858, the revenue and expenditure of the Indian empire is subjected to the control of the secretary in council, and no grant or appropriation of any part of such revenue can be made without the concurrence of a majority of the council.

Such parts of the revenues of India as may be remitted to England, and moneys arising in Great Britain, are paid into the Bank of England; and paid out on drafts or orders signed by three members of the council, and countersigned by the secretary or one of his under-secretaries. The sovereign of Great Britain is empowered to appoint from time to time an auditor of the accounts, with power to inspect all books and examine all officers, and his report is to be laid before Parliament. The accounts of the whole revenue and expenditure of the Indian empire must be laid annually before Parliament.

The subjoined table gives the total gross amount of the actual revenue and expenditure of India, in each of the years, ending April 30, from 1858 to 1864:—

Years ended Ap. 30.	In India.		Home charges.
	Revenue. £	Expenditure. £	
1858 ...	31,706,776 ...	35,078,528 ...	6,162,043
1859 ...	36,060,788 ...	43,590,794 ...	7,466,136
1860 ...	39,705,822 ...	44,622,269 ...	7,239,451
1861 ...	42,903,234 ...	41,529,973 ...	5,394,646
1862 ...	43,829,472 ...	37,245,756 ...	6,634,344
1863 ...	45,143,752 ...	36,800,806 ...	6,515,601
1864 ...	44,613,032 ...	38,087,772 ...	6,446,913

It will thus be seen that, after long years of chronic deficit—a state of things, however, which is attributable to the practice, unknown elsewhere, of constructing important public works and paying interest upon the hitherto unremunerative capital of great railways out of current revenue—India has at last exhibited an undeniable surplus; and there seems to be a reasonable certainty that this position of national solvency may now be looked upon as the normal state of things, if the country is favoured with continued peace, and the same persistent economy is manifested at head-quarters. Nearly one-half the revenue of India is derived from the tax on land, and from 10,000,000*l.* to 13,000,000*l.* a year from the opium and salt duties. In the different presidencies the government land-tenures vary. Up to 1860 it was impossible to purchase the fee simple of land, except in the three presidency cities, and in Chittagong, in Bengal; but since the last year of Lord Canning's administration waste land has been sold in fee simple very largely, chiefly to English tea and coffee planters. Settlers who have indigo or silk factories on other land may also purchase the same tenure on fair terms.

The principal sources of expenditure in India are the army, public works, police, civil administration, and interest on the public debt.

According to a parliamentary paper published in 1865, the following is the amount of stocks, loans, debts, and liabilities chargeable on the East India revenues, up to the latest period at which the return could then be made out, viz., in England, to December 31, 1864, and in India to the 30th of April, 1863:—

Registered debt, ...	£62,279,106
Loans, ...	2,862,382
Treasury notes, ...	1,614,706
Service funds, ...	5,580,290
Bills payable, ...	2,297,875
Deposits and miscellaneous, ...	12,383,570
East India bonds, ...	3,136,917
“ debentures, ...	4,868,000
India 5 per cent. stock, ...	15,720,100
“ 4 per cent. stock, ...	2,441,000
Capital of Indian railways remain- ing in home treasury, ...	1,912,351
Miscellaneous, ...	431,408
Total, ...	£115,527,705

The above is exclusive of the charge upon the revenues of India, under the Act of 3 & 4 Will. IV., c. 85, of the dividend at the rate of 10*l.* 10*s.* per cent. per annum on the sum of 6,000,000*l.*, the capital stock of the East India Company, which is subject to redemption by Parliament on payment to the company of 200*l.* sterling for 100*l.* stock.

Commercial Staples.—Several articles of commercial importance have of late years been added to Indian exports. Of these the chief are oil seeds, jute, wool, coffee, and tea; and the table annexed will show from what small beginnings the trade in these products has attained its present importance:—

Value of Exports.

	1842.	1852.	1862.
Oil seeds, £ 2,377 ...	£501,420 ...	£1,197,469	
Jute, . . . 24,941 ...	180,976 ...	537,610	
Wool, . . . 77,591 ...	100,612 ...	400,342	
Coffee, . . . 74,957 ...	84,306 ...	462,380	
Tea, . . . 17,244 ...	59,220 ...	192,242	

The great increase in the exportation of oil seeds has taken place since the breaking out of the Russian war, which closed to the English merchants their principal sources of supplies. Jute is exported only from Bengal; wool, principally from Bombay.

But the most remarkable—and it promises eventually to be the most valuable—of all the new articles of export from India is tea, which having, of late years, been found indigenous in Upper Assam, has been very successfully cultivated over extensive tracts. Plants, seeds, and skilled workmen were imported from China, and the growth of the native shrubs carefully promoted at the cost of the Indian government. The result proving satisfactory, a company was formed, under the title of ‘the Assam Company,’ having for its object the production of tea in that province. To this association, which included several gentlemen of varied experience and great sagacity, the government transferred its gardens and establishments on very liberal terms. As its operations grew prosperous, numerous imitators sprang up, and applications for grants of land flowed in from every quarter. There are now upwards of 170 plantations in Assam, owned by more than sixty companies and individuals, and producing an annual crop of nearly 2,000,000 lbs. of tea.

Nor has the adventure been confined to Assam. In the adjacent provinces of Cachar, where also the tea plant was found in a wild state, upwards of 70,000 acres have been leased to tea-planters; there

are thirty-one working concerns; and though the experiment has a development of only seven or eight years, upwards of 6500 acres have been brought under cultivation. Tea crops of excellent quality are also raised on the skirts of the Himalayas in the north-western provinces, the tea produced being, in the opinion of competent judges, superior to the China tea imported for mercantile purposes.

With equally rapid steps the cultivation of coffee has progressed in the highlands of Southern India. Tradition ascribes its introduction to a Mussulman pilgrim, who brought seven berries of coffee from Mocha about two centuries ago, and planted them near his lonely home in the wild hills of Mysore. The plant now extends over tens of thousands of acres in Coorg, the Wynaul district, the Neigherry hills, and along the western Ghauts, north and south. In Mysore, the number of European coffee-planters, says Colonel Onslow, has, within the last ten years, increased to twenty or thirty. The number of native planters is computed to be nearly 4000, and they are fast increasing. The elevation at which the plantations flourish (from 3500 to 4000 feet above the sea-level) affords a pleasant climate, well suited to European constitutions. During the south-west monsoon, the planter may ramble in his gardens all day long, and suffer no inconvenience in the hottest weather; the thermometer in the house in these plantations rises no higher than 81° or 82° Fahrenheit. The whole coffee district—or at least a few fever-blighted spots excepted—enjoys a climate in which the European can live and work with comfort, and, if moderately prudent, throughout the year.

Planting has of late years been so extensively carried out in Mysore that very little available land remains. The mountain and forest wastes have been converted into rich productive gardens. From being the wildest and loneliest parts of Mysore, these districts have grown very prosperous. The wilderness blossoms like the rose. The people have been raised from indigence to competency, and even, in many cases, to wealth. Both by the capital and example of European planters the natives are benefiting largely, and are learning the science of planting.

Cotton is also extensively cultivated, though the product is unable to compete in quality with the celebrated Sea Island kind. It will probably occupy a higher position among the staples of Indian commerce when British capital is more liberally expended on its cultivation, and its transportation to the ports of shipment is facilitated by the construction of roads and canals.

Indigo has been largely grown from the earliest date of British enterprise in the peninsula. The plant is indigenous, as its name, corrupted from *Indicum*, implies; but it was not until about 1780 that its growth and manufacture were systematically undertaken by British settlers under official auspices. From that time the Bengal drug rapidly obtained the command, nay, almost the monopoly, of the trade, which has, of late years, been shared in a minor degree by the produce of the other Indian presidencies.

To conclude. We rejoice, to use the words of an able writer in the *Edinburgh Review*, in the belief that both moral and physical agencies, already actively at work, are impelling India in its progress at a rate almost unprecedentedly rapid. This, too, is a

healthy and natural progress; the effect of causes which, 'like rain upon the mown grass,' are acting gently and almost imperceptibly, as well as equally, upon the whole breadth of society. The onward march of civilization is as plainly shown by the larger profits of the ryots, and the higher wages of the artisan, as by the improved education and diminished prejudices of the higher classes. At last the great driving-wheel of progress has been fairly set in motion, and India, under British auspices, is moving forward at a pace almost Anglo-Saxon in its rapidity.

Commerce.—Restrictions which hindered commerce and retarded the development of the resources of the country have been gradually removed within the last twenty years, and India now enjoys free trade. The dues on British and foreign shipping are the same. The inland duties, and duties on goods carried coastwise are abolished. Full details of the commerce of India are given in the articles on the different presidencies; but we may here state that India takes more British goods and manufactures than any other country in the world, the total being now annually valued at about 20,000,000*l.* sterling. In addition to this sum, specie to the value of several millions sterling is annually sent thither from this country. The exports from India to all parts of the world, which were only 14,000,000*l.* in 1841–42, had risen to 20,000,000*l.* in 1851–52, and in 1861–62 to no less than 35,000,000*l.*—an increase of 150 per cent. in twenty years. In 1863 there was an increase of 13,000,000*l.* on the latter sum—the total amount being 48,434,517*l.*—and in 1864 the exports to England alone were valued at 52,287,869*l.*

Currency.—The accounts of India are kept in rupees, annas, and pies—the rupee being valued at 2*s.*, the anna at 1½*d.*, and the pie at a twelfth of the latter sum.

Railways.—As upwards of 50,000,000*l.* of English capital are invested in Indian railways, we shall enter more fully than usual into this division of our article, so as to enable our readers to form a just appreciation of their importance and magnitude.

It is now twenty-one years since the first railway companies in India were proposed, but only fourteen years since a commencement was made in their actual formation. The East India and Great Indian Peninsula railways were projected in 1844, but it was not until 1849 that operations were commenced on the latter line, nor until 1853 that the first twenty-two miles of railway were actually opened in the Peninsula. After this preliminary delay, the works proceeded slowly until 1858, when an inquiry was made into the causes of the slow progress of the various lines towards completion; and it was found that the delay was partly caused by the impediments occasioned by the necessary government supervision, at home and in India, over lines upon which they had given a guarantee; partly by the incidental delays occasioned by the execution of public works at a distance; partly by the Sepoy mutiny; and partly by the natural difficulties in construction. After 1858 the railway works proceeded more rapidly, and there are now (March, 1866) nearly 3500 miles open to traffic, against 436 in 1859.

The government of India promoted the formation

of two descriptions of lines, trunk lines and feeders; and by two kinds of assistance—a qualified guarantee of interest upon capital, and a direct annual subsidy; both for a certain term of years. The guarantees are for the term of ninety-nine years from the dates of the contracts entered into between the government and the different companies, but the interest is only paid on the capital specially authorized to be raised by the government, and which has been expended according to its direction and under its inspection. When the railways are constructed and earn more than the guaranteed rate, they are to refund the money advanced by the government on their behalf, setting apart half of the excess profits above 5 per cent. for that purpose. During the last fourteen years over 13,000,000*l.* have been paid by the government in the shape of guaranteed interest, of which 3,300,000*l.* has already been paid back, and there can be no doubt that in a few years not only will the government be relieved of the present annual payments altogether, but will have received back the large sum now due to it. In the meantime, it obtains advantages which fully compensate for the liability it has incurred.

The other form of government assistance to Indian railways—viz., an annual subsidy for twenty years—is a guarantee of about $2\frac{1}{2}$ per cent. per annum upon lines whose average cost is from 4000*l.* to 5000*l.* a mile. This can, therefore, only be of service to railways of a light description, and which can hardly be expected to do much more than act as feeders to the larger lines.

As a further privilege to the Indian railways, it has been arranged that any company may, after the railway has been finished and in operation for three months at least, and at any time within ninety-nine years from the date of contract with the government, give six months' notice of their intention to relinquish the railway; and at the expiration of that time hand it over in good working order to the government, who will repay all authorized sums expended, subject to deduction of unsatisfied claims against revenue. On the other hand, the government has the power to purchase the railways at any time within six months after twenty-five or fifty years from the date of the several contracts with them. The price, in either case, will be the mean value of the stock or shares for the three years previous to the surrender or purchase. At the expiration of ninety-nine years from the date of each contract (supposing the railway neither previously bought by government nor relinquished by the company), the land and works will become the property of the government, and the rolling-stock will be purchased by it at a valuation; but as the companies have at all times within the ninety-nine years the power of surrender at a mean three years' value of their stock or shares, they are protected against being compulsorily denuded of their property by this last privilege of government, which may be considered as virtually inoperative.

From the commencement of railway operations in India the government has assumed the power of fixing the routes of all the lines; and at the beginning of the system of promotion by guarantee, certain trunk lines were laid down to be made, which, while they would be of commercial value,

would also improve the political and military communications of the country, by connecting the three presidencies by railway.

When the main lines at present in process of construction are finished, they will combine with the Indus flotilla to form five great arteries for traffic from east to west.

The first and most northerly will be from Calcutta on the east to Kurrachee on the west, being composed of the East Indian Railway from Calcutta to Delhi; of the Delhi line, from Delhi to Umritsur; of the Punjab Railway, from Umritsur to Mooltan; and of the Indus steam flotilla (which will probably some day be superseded by a railway) from Mooltan to Kotree; and of the Scinde Railway, from Kotree to Kurrachee.

The second great route is from Calcutta to Bombay, the line being formed by the junction of the southern branch of the East Indian Railway from Calcutta, and of the northern branch of the Great Indian Peninsula Railway from Bombay—the two lines meeting at Jubbulpore.

The third great route is from Madras to Bombay, and consists of a junction at Raichore between the southern branch of the Great Indian Peninsula from Bombay and the northern branch of the Madras Railway.

The fourth route is from Madras on the east to Beypore on the west coast, the whole distance being traversed by the Madras Railway.

The fifth route is from Negapatam to Beypore, and is to be formed by the junction of the Great Southern of India Railway from Negapatam with the Madras and Beypore line at Errode.

The east and west of India are therefore intended to be united by five direct lines; but as each and all of these are to be connected by one general system, a communication for interchange of traffic will also be effected between the north and south.

The following was the state of each line, according to the official report, on May 1st, 1865:—

Railway.	Total Length as at present sanctioned. Miles.	Length (1st May 1865). Miles.	Length remain- ing to be finished. Miles.
East Indian—			
Main line, . . .	1271½	1126	145½
Jubbulpore line, . . .	225	—	225
Great Indian Peninsula, . . .	1266	595½	670½
Madras—			
S. W. line and Bangalore branch, . . .	492	492	—
N. W. line, . . .	360	79	281
Bombay, Baroda, and Central India, . . .	312	306	6
Scinde, . . .	114	114	—
Punjab, . . .	253	252	—
" Delhi, . . .	320	—	320
Eastern Bengal, . . .	114	114	—
Great Southern, . . .	161	79	82
Calcutta and S.-Eastern, . . .	29	29	—
Total, . . .	4917½	3186½	1730½

It will thus be seen that of the present system of guaranteed railways in India, 3186 out of 4917 miles were open for traffic on May 1st, 1865, and about

1700 miles consequently remained to be completed. It is estimated that when the system is finished with a single line it will have cost about 77,500,000*l.* Of this sum about 57,600,000*l.* had been raised, and 55,000,000*l.* had been expended, on the 1st May, 1865. The materials which have already been sent out from England to aid in the construction of the railways amount to 2,900,000 tons, and 16,500,000*l.* has been expended upon them. The average cost per mile has been below that of the English lines. The East Indian cost 20,000*l.* per mile; the Madras only 11,000*l.* The track is laid on a uniform gauge of 5½ feet. The amount received from passengers in the year ending the 30th June, 1863, was 682,343*l.* In the year ending the 30th June, 1864, it was 981,948*l.* The amount received for the conveyance of goods in 1862-63 was 948,324*l.*, and in 1863-64, 1,406,963*l.* The net profits in the year 1862-63 amounted to 690,834*l.*, and in 1863-64 to 947,320*l.* The number of passengers conveyed in 1863-64 was 11,781,683, compared with 9,242,540 in 1862-63. Of those who travelled, 1·12 in every 100 used the first class, 4·78 used the second class, and more than 94 per cent. were third class travellers. The fares in India are much lower than in England, being generally 1½*d.* per mile first class; 1*d.* or ¾*d.* second; and ½*d.* or ⅓*d.* third. The government have the power to fix the fares, and are of opinion that low ones, as compared with those of Europe, are perfectly compatible with large and remunerative receipts. When completed, the traffic on the main lines will, doubtless, be enormous. If this traffic be properly conducted, and if economy prevail in the various departments connected with the working and maintenance of the lines, the results will be very satisfactory. But whether, as commercial undertakings, their success is great or moderate, no country in the world will, either directly or indirectly, derive greater advantages from railways than India.

Some of the engineering works connected with the Indian railways are among the finest in the world, especially the bridges and viaducts.

Over the river Soane, on the East Indian line, between Patna and Benares, a bridge has been thrown which is the longest but one (the Victoria, over the St. Lawrence, in Canada) in the world. It is about twice the length of the Charing Cross railway bridge over the Thames, and consists of twenty-seven iron girders of 150 feet each, supported on brick foundations.

The Great Indian Peninsular Railway crosses the Western Ghats, a range of lofty mountains, at the Bhore Ghaut, near Callian. The length of the incline from the base to the summit is 15 miles 68 chains. The level of its base is 196 feet above the sea, and of its summit 2027 feet; so that the total elevation surmounted is 1831 feet; the average gradient being one in forty-eight, and the steepest gradient one in thirty-seven, for one mile and 38½ chains. Several of the embankments on this line exceed 60 feet in height; many of the outer slopes are 150 feet in length, and some of them as much as 300 feet. The greatest depth in the centre line of cuttings is 74 feet; and in one cutting the excavation on the upper side is nearly 150 feet deep, through solid rock. The total length of tunnels is more than

ten miles and a quarter; and of the viaducts and vaulting arches about three-quarters of a mile. One viaduct consists of eight 50 feet arches, 143 feet from the surface.

The *branch lines* will form an important feature of the Indian railway system. They are chiefly laid down, or to be laid down, on a four-foot gauge, with rails only 31 lbs. per yard. The average expense will not exceed 4000*l.* per mile.

In opening up the Indus valley by means of steam communication the Indian government has laid the foundation of an important commercial revolution. The Indus and the Ganges are, respectively, the great natural water-ways of Western and Eastern India. It is said that a line drawn between Agra and Delhi represents the approximate boundary between the countries dependent on either river, had both afforded equal commercial facilities. But until the new era of the railroad and the steamboat such was not the case. Exceedingly difficult and dangerous was the navigation of the Indus, and sand bars choked up the port of Kurrachee. Nor were political obstacles wanting. Exorbitant toll was levied by the Ameers of Scinde on every passing trader, so that the Ganges route was naturally preferred to that of the Indus, and Bombay and Calcutta flourished at the expense of Kurrachee. But political difficulties were swept away in 1844 by the conquest of Scinde, and the conqueror, Sir Charles Napier, at once perceived the commercial and military importance of Kurrachee. 'Kurrachee,' he exclaimed, 'you will yet be the glory of the East! Would that I could come alive again to see you in your grandeur!' His dreams are being fulfilled; wharves and quays are alive with traffic; the Scinde line of railway connects it with Kotree; while the Punjab railway and the Indus steam flotilla are rapidly restoring the Indus to that importance as a great commercial channel which it formerly enjoyed.

We may add, in the words of a well-informed authority, that the Indus channel of trade is also the natural gate of Central Asia. Hitherto the trade of India with Central Asia has amounted only to about 1,000,000*l.* sterling per annum, transported by camels, mules, and ponies, and crossing the Brahooic chain at the Bolan Pass, and the Hindu Koosh at the Khyber Pass. This trade admits of great and immediate expansion. Hitherto the supply of Central Asia has been almost monopolized by Russia through her Volga and Caspian route. Russian manufactures had even competed successfully with ours at Lahore and everywhere throughout the Punjab. Under the present circumstances, we may hope to be able not only to supersede Russian manufactures by British in India itself, but by introducing British and Indian manufactures along the valleys of Afghanistan as far as Herat, and into Balkh, Khiva, and Bokhara, wrest from Russian merchants a large portion of their trade. A railroad to Peshawur, at the foot of the Khyber Pass, would thus serve the twofold purpose of guarding the Indian frontier against the aggression of Russian arms, and combating the influential position which Russian commerce has attained in Central Asia.

Roads.—The development of the traffic on most of the railways is still, to a great extent, retarded by the absence, or the imperfect condition, of the roads

leading to the stations, and hitherto the government have been unable, without neglecting other even more important claims, to devote a large share of the public funds at its disposal for their construction and improvement. Great efforts are, however, every year being made in this direction, and there are already several thousand miles finished.

Canals and Irrigation.—It is asserted by Sir Arthur Cotton, under whose direction most extensive works for irrigation and navigation have been executed in Madras, which are paying the government about 100 per cent. for their investment, and who may, therefore, be considered a good authority on the subject, that whatever else railways may do, it is impossible for them to supply *cheap* transit for goods in a continental country like India. To attain that, he says, the development of water transit is an absolute necessity, and no country in the world affords greater facility for doing this than India. In a recent report on the East India canals the Governor-General in Council also states that, although so much has already been done by the officers of the canal department, their progress must be still further advanced, and he desires to impress upon the government of the north-western provinces, the increasing importance of watching with close attention the development of irrigation in the districts of Upper India.

The first great work of irrigation undertaken by the British government, and completed between the years 1808 and 1822, was the restoration of the great Mogul canals, which had become choked up or dilapidated by neglect during the wars of the previous century. Of these the Eastern Jumna Canal, with 150 miles of main line and 500 miles of distributing channels, waters 160,000 acres. The Western Jumna Canal has a main channel of the far greater length of 445 miles, exclusive of distributing channels. In the famine of 1837-38, the value of crops saved by this canal was estimated at 1,462,000*l.*, giving food to the inhabitants of 500 villages. It irrigated at that time 212,241 acres. To restore, extend, and improve these canals was a work of great difficulty, but it sinks into insignificance when compared with the Ganges Canal, a purely British design, the main channels of which extend to a length of 898½ miles; which receives at its head no less than 6750 cubic feet of water per second; and which has attached to it nearly 2000 miles of distributing watercourses, besides many hundred miles of minor channels. No work of irrigation in any country will bear comparison with it either in the magnitude or in the extent of the benefits it will bestow upon immense bodies of mankind. It is calculated to irrigate an area of 1,471,500 acres, and will protect from risk of famine a country containing a population of no less than 6,500,000.

Many important works of irrigation have been completed or are under construction in the Debra Dhoon (fast becoming a sheet of tea plantations), Rohileund, Bundelcund, and several parts of the Punjab; and in the Presidency of Madras nearly all the rivers have been compelled to stay their downward course to the Bay of Bengal, and contribute at once to the fertilization of the land and the transport of merchandise. The two greatest works are the Krishna annicut, which serves 350,000 acres of land, and the annicut which controls the

waters of the Godavery. The three old British provinces of Bengal, Bahar, and Orissa have hitherto had less attention paid to their means of irrigation than other parts of India—probably on account of the greater amount and certainty of the rainfall which they enjoy; but at last public attention has been seriously directed towards their wants and capabilities in this respect, and most extensive works are now in contemplation or actual course of construction.

The results of the canals and works of irrigation hitherto carried out have been most beneficial. They may be said to be absolute preventatives of famine, heretofore the most frightful scourge of India, in those seasons, of not unfrequent occurrence, when the rainfall in the plains is greatly below the average; and they are at the same time an almost equally effective safeguard against inundations, which were formerly almost as terrible in their effects as the seasons of drought.

The main channels of most of the canals are also used for purposes of navigation as well as irrigation.

Telegraphic and Postal Communication.—The electric telegraph has already linked together all the principal cities and civil and military stations in India, and it was found of great service during the mutiny. Altogether about 12,000 miles are open. In 1865 a line was opened connecting Calcutta with London, *via* Constantinople and Bagdad, by means of which daily communication is established between England and India. A portion of it is submarine, and traverses the Persian Gulf for 1550 miles, at a depth of from thirty to sixty fathoms. Hyderabad, Madras, Mysore, and Ceylon are connected with Calcutta by an important branch line of telegraph, while Mysore and Beypore; Madras, Poonah, and Bombay; Bombay, Surat, Hyderabad, and Kurrachee; Kurrachee, Lahore, Agra, Delhi, and Calcutta, represent the principal points on four of the greatest branches of the Indian telegraphic system.

The postal communication of India extends over nearly 50,000 miles. The rate is only half an anna, or ½*d.*, for a single letter, which is lower than in any other country. There is a weekly communication between England and India by the overland route, first laid down by the exertions of Lieutenant Waghorn, *via* Egypt and the Red Sea. The time occupied from London to Bombay is from twenty to twenty-five days; to Madras about a month; and to Calcutta from thirty-five to forty-two days.

Religion and Education.—The religion of the natives of India is noticed in the article HINDUSTAN. The first attempt to bring the country under the influence of Christianity is said to have been made by the apostle Thomas; but whether this is true or not, it is certain that a Syrian church was planted at Malabar at a very early period. In the sixteenth century Roman Catholic missions were introduced by the Portuguese, and the number of Catholics in the country is still greater than that of any other Christian denomination. The first Protestants came from Holland and Denmark, and early in the eighteenth century the English societies of Christian Knowledge and for the Propagation of the Gospel assisted the Danish mission established in Southern India. Subsequently all missionaries were excluded by the East India Company, but in 1793 the restriction was

withdrawn and the Baptist Society sent out its first agents. Since that period various other societies have augmented the number of missionaries, and they are now scattered all over the country. Many thousand converts have been made, but the results have been by no means so striking as in many other parts of the world, owing to the peculiarities of the Hindu character, and the very great reverence they feel for their ancient faith. The government excludes the Bible from the public schools—a measure which has often been strongly censured—but about 250,000 copies of the scriptures in different languages have been distributed amongst the natives by the missionaries.

The fullest toleration in matters of faith is enjoyed throughout India; and it is decreed in the Queen's first proclamation to the people, that none shall be in anywise favoured, and none molested or disquieted, by reason of their religious faith and observances, but that all shall alike enjoy the equal and impartial protection of the law. It is only when fanaticism seeks to enforce the cruel suttee, or offer human beings in sacrifice, that the government interferes. Clergymen of the Church of England and Scotland, and Roman Catholic priests, are retained on the government establishment as civil and military chaplains, and state grants are still paid to a few Hindu temples and Mohammedan mosques, as under the past régime; but wherever possible these claims have been and are compromised either by a grant of land or one money payment. There are Anglican bishops at Calcutta, Madras, and Bombay.

For some years past the government of India has been devoting laudable attention to education, which was put on a new footing, and a university established in each presidential city, in 1854. Many schools and colleges are endowed by the government, and grants in aid are made to non-government and missionary educational establishments. English is taught in nearly all schools, and is highly prized by the native youth of India as a means of employment in government and mercantile offices.

From the preceding information it will be seen, that very much has been and is still being done for the physical, intellectual, and social progress of India, and there can be but little doubt that if the natives will but co-operate with the government the material advancement of that great country during the next fifty years will be such as the world has never yet seen in the case of an ancient and long-settled people. As the European race so rapidly degenerates, and in a few generations becomes physically weakened and mentally enervated, on account of the unhealthiness of the climate, colonization, in the strict sense of the word, will always be impracticable; but for British capital and energy India now promises one of the most secure and profitable fields of investment of any of our colonies and dependencies.

Historical Summary.—In our article on the EAST INDIA COMPANY we have briefly referred to the growth of that remarkable association, which for a century ruled over a hundred millions of subjects. The prosperity of British India dates from the victory of Plassey, won by Clive, on the 23rd of June, 1757, over the forces of Surajah Dowlah, the nabob of Bengal. This great battle rendered the British supreme in Bengal, and enabled them to concert

measures for the expulsion of their French rivals, which was finally effected by Colonel Coote's victory at Wandemash, on the 22nd of January, 1760, and the capitulation of their principal city, Pondicherry, on the 15th of January, 1761.

Meanwhile, Clive, who had been raised to the post of governor of Bengal, exerted all his subtlety and vigour in consolidating the conquests and establishing the power of the Company, while he effected the most necessary reformatations in both the civil and military departments. Finally, the revenues of Bengal, Bahar, and Orissa were formally assigned to the Company by the Mogul emperor, and all the territories conquered by its soldiers within the nominal extent of his dominions. Thus a body of comparatively obscure merchants had acquired a demesne equal in area to the most flourishing European kingdom, and from this date, 1765, commences the recognized sovereignty of the British in Hindustan.

In the south of the peninsula the Company had acquired the supremacy of the Carnatic, and entered upon measures of conquest which speedily brought them into collision with Hyder Ali, the able sultan of Mysore. So great, indeed, was its political and territorial importance that the government of Great Britain felt it necessary to intervene, and claim a share in the administration of British India. In 1773, Parliament enacted that all civil and military correspondence should be submitted to the king's ministers; that a supreme court of judicature should be sent out from England; and that the presidencies of Bengal, Madras, and Bombay should be subject to a governor-general and council, the former to be nominated by the Crown.

The first governor-general under this new system was Warren Hastings, a man of extraordinary capacity and relentless will, who, in the face of violent opposition from his own council, extended British supremacy, defeated Hyder, its most powerful enemy, and wrested from Asef-ad-Dowla, the subahdar of Oude, the Zemindary of Benares. He reigned twelve years in Hindustan, and during that period raised the Company's revenue to double its previous amount. On his return to England his services were rewarded by impeachment, and he was tried before the House of Lords on various charges of bribery, corruption, and oppression. The trial, owing to various circumstances, was protracted for seven years, and terminated in an honourable acquittal. Warren Hastings lived to enjoy a calm old age, happy in the recollection that he had founded a policy, had administered government and war with more than the ability of a Richelieu, and patronized learning with all the liberality of a Medicis.

Lord Cornwallis, a soldier of experience and repute, succeeded as governor-general in 1786. His administration was eminently successful; he consolidated the alliance of the Company with the independent native princes, and in a war with Tippoo Sahib, the son and successor of Hyder Ali, defeated his armies, and invested his capital of Seringapatam. Tippoo only saved his crown by the cession of considerable territory to the British.

In 1793 Sir John Shore assumed the reins of government, but he adopted a pacific course of policy, which, however suitable for a consolidated empire, did not meet the wants of an empire still in the

process of building up, and tended to lower the prestige of the British among the native princes. In 1798 he was succeeded by a man of more resolute character and of far greater sagacity, Lord Mornington, afterwards Marquis of Wellesley, during whose viceroyalty Seringapatam was captured by assault (May 5, 1798), the greater part of the Deccan annexed to the Company's territories, and the Mahrattese chiefs overthrown by Sir Arthur Wellesley (afterwards Duke of Wellington) at the memorable battle of Assaye. The upper part of the Douab, with Delhi and Agra, Cuttack, and part of Guzerat, were also taken possession of by the British.

After a brilliantly successful career, the marquis of Wellesley returned to England and was succeeded in the governor-generalship by Lord Cornwallis (1805), who died soon after his arrival at Calcutta. Lord Minto replaced him in 1807, and distinguished his viceroyalty by subduing the remaining possessions of the French in the East.

From 1813 to 1823 British India was ruled by the marquis of Hastings, under whose direction the fame of the British arms crossed the Himalayas and penetrated into the mountainous districts of Nepal; the Pindarees, a race of freebooters, were annihilated; and the whole of Hindustan was brought immediately under the power or indirectly within the control of the British government.

Assam, Arracan, and the Tenasserim provinces were annexed to the Company's territories by Lord Amherst (1826), and year after year the splendid fabric of British supremacy received some substantial addition through the policy of our statesmen and the bravery of our soldiers. Lord Auckland's government was fatally marked by the disasters which befell the British arms in Afghanistan (1841); disasters in some degree retrieved by his successor, Lord Ellenborough, under whose auspices the capture of the cities and citadels of Ghuznee and Cabool was effected by Generals Nott and Pollock. In 1843 the genius of Sir Charles Napier annexed to the Anglo-Indian empire the territories of Scinde and Beloochistan, and during the splendid administration of the marquis of Dalhousie, an iron-handed and far-seeing ruler, the whole was crowned by the conquest of the Punjaub, Nagpoor, Oude. The viceroyalty of Lord Canning was marked by the breaking out of the Sepoy mutiny; the tragic scenes at Meerut, Cawnpore, and Lucknow; its final repression by Havelock and Lord Clyde: a series of events which brought into vivid relief the intrepidity, courage, and heroic resolution of British statesmen and British soldiers in the Far East, and eventually resulted in the abolition of the East India Company as a political power, the authority of the Crown being established by law throughout the great Indian empire. The present governor-general (1866) is Sir John Lawrence.

(Probably the best work of general reference on India is Mr. Montgomery Martin's *Progress and Present State of British India*, London, 1862—a work to which we are indebted for much of the preceding information. We have also consulted the *Statesman's Year Book* for 1866; *Official Report on Railways of India* for 1865; *Reports on Irrigation and Navigation*, by Lieutenant-Colonel R. Baird Smith, Sir Arthur Cotton, and others; G. O.

Trevelyan, *The Competition Wallah*; and numerous Parliamentary Papers.)

INDIAN CORN. [MAIZE.]

INDIAN INK. [INK.]

INDIAN OCEAN is the name given to the vast oceanic basin separated from the Pacific on the east by the Asiatic Archipelago and Australia, bounded on the south by a line drawn from the Cape of Good Hope to Bass' Strait, divided from the Atlantic by Africa on the west, and inclosed by the countries of Asia on the north. The principal inlets are the Bay of Bengal, the Arabian Sea, and Gulf of Oman, the Persian Gulf, and the Red Sea. Steam packets are established between the principal ports, which are Calcutta, Bombay, Malacca, Aden, Muscat, Zanzibar, &c. The most important islands are Madagascar, Mauritius, Bourbon, &c. The monsoons or periodical winds prevail in the northern part of the ocean, blowing from the south-west between April and October, and from the south-east during the rest of the year. Tempests are general at the periods of change; and between latitudes 5° and 40° south violent hurricanes occur.

INDIAN RUBBER. [CAOUTCHOUC.]

INDIAN TERRITORY, a large tract of land set apart by the Federal government of the United States for the permanent residence of the various tribes of native Indians removed from the settled states and territories of the Union. It lies between 33° 30' and 39° N. lat. and 94° and 100° W. long., bounded south by Texas, east by Arkansas and Missouri, and north by the new state of Kansas; the area is about 187,000 square miles; the Indian inhabitants are estimated at about 120,000. The principal Indian tribes settled in the territory are the Cherokees, 17,600; the Creeks, 25,000; the Choctaws, 16,000; the Osages, 4941; the Chickasaws, 4709; the Potawatomes and Chippewas, 4680; the Pawnees, 4500; the Seminoles, 3000; the Saes and Foxes, 2373; the Shawnees and Senecas, 1400; the Delaware, 1130, &c., under the guidance of missionaries who have settled amongst them: and with the sanction and assistance of the Commissioner of Indian Affairs, some of the larger tribes have established regular governments, legislatures, medical officers, churches, schools, newspapers, &c.

INDIANA, one of the united states of North America, is bounded S.E. by the river Ohio, which divides it from Kentucky, E. by the state of Ohio, N. by Michigan, and W. by the state of Illinois. It lies between 37° 37' and 41° 45' N. lat., and between 84° 42' and 87° 49' W. long. Its length is 276 miles and breadth 140 miles—the entire area being 33,809 square miles, or 21,637,760 acres. The population in 1800 was 4875; in 1810, 25,520; in 1820, 147,178; in 1830, 343,031; in 1840, 685,866; in 1850, 988,416; and at the last census (1860) 1,350,428, of whom nearly one-half were emigrants from other states, and from Germany and Ireland.

The Ohio and the Wabash are the most important rivers. [OHIO.] The Wabash rises in Ohio, and flows thence into this state. Its whole course through Indiana, and along its western boundary, is between 500 and 600 miles, all navigable except at its falls or rapids. All the other principal rivers of the state are tributaries of the Wabash: the

White River is formed of two main branches, of which the northern has a S.W. course of about 300 miles, and the East Fork has also a general S.W. course of 200 miles. The Wabash also receives the Tippecanoe and the Eel River from the N.E., then the Missisnewa from the S.E., and Little River from the N.E. Many streams fall into the Ohio, but none of much magnitude. The same remark applies to those which flow into Lake Michigan.

Surface.—This state, like Illinois, slopes to the S.W. Like that state also, it is, with few exceptions, one great plain. There is indeed a tract of hilly country north of the great bend of the Wabash, and the state is skirted on the south by those eminences called the Ohio hills, which sometimes touch the Ohio and sometimes retire from it for two or three miles; they occasionally rise 300 feet above the river. The timbered and prairie lands are more intermixed in this state than is usual; and the alluvial river-bottoms are all wide. The soil is admirably suited for grass and grain. The climate is somewhat more equable than that of Illinois, and milder than that of western Pennsylvania. It is everywhere healthy except in the neighbourhood of the wet prairies and swamps. Iron, copper, coal, marble, lime, freestone, and gypsum, are found.

Products.—Indiana produces an abundance of wheat, oats, potatoes, butter, cheese, wool, maize, tobacco, and a little cotton; swine and cattle are also reared. The most successful vineyards in the United States are at Vevay on the Ohio. They are managed by the Swiss settlers at that place, and consist of native species of the vine.

There are over 2000 miles of railway in the state, and a canal, 467 miles in length, uniting the Ohio river with Lake Erie, passes through it.

Chief Towns, &c.—Indiana is divided into ninety-one counties. The following are the principal towns, with their population in 1860:—*Indianapolis*, the capital, near the centre of the state, on the east bank of White River, which is navigable thus far at high water. Population, 30,000. It is a regularly built and beautiful city, with a handsome state-house, court-house, and asylums for the blind, deaf and dumb, and insane. It also has a university, two female colleges, thirty churches, and extensive woollen factories, iron foundries, planing mills, and flour mills. *La Fayette* is 65 miles N.W. from Indianapolis. Population, 9387. It has a court-house, gaol, market-house, bank, and seven churches, and is connected by canal with Lake Erie. *Marlison*, on the north bank of the Ohio, 88 miles S.E. from Indianapolis, has an active trade. Population, 8133. *New Albany*, on the north bank of the Ohio, 121 miles S. by E. from Indianapolis, has a court-house, gaol, and numerous places of public worship. Population, 12,647. The town is regularly built, has establishments for steam-boat-building, an engine factory, and a theological college. There is excellent railway accommodation. *Terre Haute* is situated on the east bank of the Wabash. Population, 8000. *Vevay*, 94 miles S.E. from Indianapolis, on the northern bank of the Ohio, was settled by emigrants from Switzerland. *Vincennes*, on the east bank of the Wabash, 118 miles from Indianapolis, was settled by the French in 1702, and is the oldest town in the state.

In 1860 it contained thirteen incorporated colleges (one or two of which receive pupils of both sexes), theological, law, and medical schools. The public revenue amounted to 3,851,456 dollars.

There are deaf-mutes, blind, and insane asylums, and numerous churches of all denominations.

In 1860 there were 337,390 students attending the public schools.

The legislative body consists of fifty senators and one hundred representatives. The state sends eleven representatives to Congress.

Indiana was included in the cession of Virginia to the United States in 1787. It was placed under a territorial government with Illinois in 1800, and under a separate government in 1809. In 1816 it became a state, and formed its present constitution.

INDIANS, AMERICAN. [NORTH AMERICAN INDIANS.]

INDICATORINÆ, Mr. Swainson's name for the Honey guides, a subfamily of cuckoos (*Cuculidæ*).

There appears to be but one genus, *Indicator* (De Vaillant), which is thus characterized:—Bill straight, finch-like; the base triangular; the sides compressed. Culmen and gonys equally inclined towards the tip; gonys angulated. Wings lengthened, pointed. Tail moderate, rounded. Feet short. Middle toe much longer than the tarsus. Locality, Africa.

The species are not numerous. The stories told of these birds indicating the nests of bees, and guiding men to them by their motions and cries, from the time of Sparrman downwards, appear to be perfectly authentic, though some great travellers affected to disbelieve them.

Mr. Steadman, in his 'Wanderings and Adventures in South Africa' (1835), says, 'The little honey-sucker, or indicator, kept fluttering before us with its cry of *cherr, cherr*, as if inviting us to follow. It is frequently known to conduct travellers to a nest of honey deposited in the hollow of a tree. I have, however, heard many instances mentioned of its stopping short of the hive, and hovering over a spot where a lion or tiger has been reposing, justly establishing its character as an indicator.' [CUCULIDÆ; CUCULINÆ.]

INDICTION. [CHRONOLOGY.]

INDICTMENT is a written accusation against one or more persons of a crime or misdemeanour referred to and presented by a grand jury. The decision of the grand jury is not a verdict upon the guilt of the accused, but merely the expression of their opinion that the matter is fit to be submitted to the common jury; and in conducting the inquiry the evidence in support of the accusation only is heard. If the grand jury think the accusation groundless, they indorse upon the bill 'not a true bill,' or 'not found;' if the contrary, 'a true bill;' and in finding a true bill twelve at least of the grand jury must concur. When a bill is found to be a true bill, the trial of the accused takes place in the usual form; and when the bill is found not to be true, or, as it is frequently called, 'ignored,' the accused is discharged, but a new bill may be preferred against him before the same or another grand jury.

INDIGESTION. [DYSPEPSIA.]

INDIGITES, among the classical ancients, a name given to the local or inferior divinities, or to demi-gods who had existed on earth, and from

their meritorious deeds were entitled to divine honours.

INDIGO, a well-known and beautiful blue vegetable colour, which is extensively employed in dyeing and calico printing. The plants from which it is mostly obtained belong to the genus *INDIGOFERA*. Their cultivation is extensively carried on in various parts of India and America. In the spring the seeds are sown at the rate of about a dozen pounds per acre. The plants grow rapidly, beginning to blossom in about three months, when they are cropped and allowed to grow till sufficiently matured to admit of another cutting. Occasionally a third and even a fourth cropping is made, but each of these contains less and less of the colouring matter that yields the colouring principle. When growing, the plants present no appearance that would lead an observer to suppose they contained any colouring matter; nor is it even yet satisfactorily determined in what form the colouring matter pre-exists in the vegetable tissue.

When the plant is in full flower, it contains most colouring matter. It is then cut, and put into vats and covered with water; fermentation takes place, accompanied with the evolution of carbonic acid and of other gaseous products, and the copper-coloured liquor is covered with a froth which in a little time becomes of a violet colour. The liquor is then run off into another vat, placed at a lower level than the first. Here it is brought well into contact with the air by being beaten with wooden paddles for about an hour and a half. During the beating the liquor darkens in colour, and the indigo separates into flocks. These are allowed to subside, heated to boiling in order to remove certain impurities, then collected on wooden strainers, and finally pressed, dried, and the mass cut up into blocks for sale.

The usual appearance of indigo as it occurs in commerce is that of nearly cubical cakes of an intense blue colour and earthy fracture. Indigo seldom contains more than about half its weight of pure colouring matter, and frequently much less.

When common indigo has been treated with dilute acids, alkalies, and alcohol, the remainder is *indigotin*, or indigo, nearly in a state of purity. It is composed of hydrogen, 3.93; carbon, 72.34; oxygen, 12.60; nitrogen, 11.13.

Indigo was well-known to the ancients, but was not employed in Europe till the sixteenth century. Owing to the jealousy of the growers of the native woad, its importation into England was even then prohibited; and it was not till the time of Charles II. that this obstacle was overcome.

The great value of indigo as a dyeing material, and the enormous extent to which it is used, have procured for it a large share of the attention of scientific chemists; and many compounds of great interest have been derived from it.

In 1864 the total quantity of indigo imported into the United Kingdom was 76,214 cwts., of the value of 2,248,112*l*. The supplies were chiefly from India: 47,532 cwts. from Bengal, 14,450 cwts. from Madras, and 3099 cwts. from Pondicherry. In the same year 57,664 cwts., value 1,700,848*l*., were exported; principally to Holland, Belgium, Hamburg, Russia, and the United States.

INDIGOFERA, a genus of plants of the natural family of *Leguminosae*, indigenous in the equinoctial

parts of Asia, Africa, and America, and celebrated for some of the species yielding indigo. The species are about 150 in number. *I. tinctoria* is the species generally cultivated in India, whence it has been introduced both into Africa and America. *I. anil* is said by De Candolle to grow wild in America, and to be cultivated in both Indies, as also along the Gambia in Africa. *I. cœrulea* is a new Indian species described by Dr. Roxburgh, who states that from the leaves he had often extracted a most beautiful light indigo, more so than he ever could from the common indigo plant. It flowers during the wet and cold seasons. *I. argentea* is the species cultivated in Egypt and Barbary for the sake of its indigo, and, according to Humboldt, also in America. *I. disperma*, according to Humboldt, is also one of the species cultivated in America, and seen among the most ancient hieroglyphical paintings of the Mexicans. Dr. Bancroft considers it as the species called Guatemala indigo, which yields fine pulp, but is less productive than other species.

Plants of other genera are also employed for obtaining indigo; as *Wrightia tinctoria*, *Marsdenia tinctoria*, *Galega tinctoria*, but especially the two first. Dr. Bancroft also adduces *Spilanthes tinctoria*, *Scabiosa succisa*, *Cheiranthus fenestralis*, and several others, as all yielding a blue dye, or coarse sort of indigo.

INDORE, a city of Hindustan, and the capital of the principality of the same name, is in 22° 42' N. lat., and 75° 50' E. long. It is a modern city, the old city on the same site having been wholly destroyed by fire by Scindia, in 1801, during the war between that chief and Holkar. The population is now about 15,000. The streets are spacious and paved; a great proportion of the houses are of two stories, and built of masonry, but there are many mud dwellings interspersed. There is a British residency here; and in the mutiny of 1857 the place acquired considerable notoriety. Though Holkar, the rajah, remained faithful to the British government, his troops mutinied, and, holding their prince as a prisoner in his own palace, butchered many Europeans, men, women, and children, in cold blood. *Indore*, the principality, consists of several detached tracts lying along the river Nerbudda, and on the northern side of the Vindhya mountains. It is ruled by the descendant of a famous Mahratta dynasty, under the title of Maharajah.

INDRE, a department in France formed out of the western portion of the old province of Berri, is bounded N. by the department of Loir-et-Cher, E. by that of Cher, S. by those of Creuse and Haute-Vienne, and W. by those of Vienne and Indre-et-Loire. It lies between 46° 21' and 47° 16' N. lat., 0° 53' and 2° 12' E. long., and measures 64 miles in its greatest length, with a mean breadth of 54 miles. The area is 2624 miles, and the population in 1863 was 270,054.

Surface.—The department is generally very flat; the only hills of any considerable size are the granitic swells on the southern border, and the gentle slopes that diversify the valleys of the Creuse and the Indre. The surface presents three marked and distinct divisions. The first, called *Bois-Chaud*, comprises seven-tenths of the whole department, including the arrondissement of La-Châtre, a great portion of

those of Châteauroux and Le-Blanc, and a third of that of Issoudun; it is divided, where arable, into a great number of small farms, and presents a very varied appearance, from the number of its hedges, ditches, and woods. The second division, distinguished by the name of *Champagne*, is a flat treeless country, without hedge or inclosure of any kind, divided into large farms, and comprising two-thirds of the arrondissement of Issoudun and a part of that of Châteauroux. The third division, called *La Brenne*, comprises parts of the arrondissements of Châteauroux and Le-Blanc, and presents a flat surface, without inclination, and covered with shallow ponds, which rest on a bottom of compact clay, and which, by their pestilential exhalations, are very injurious to health. The land varies greatly in quality, from light moss or barren sand to stiff clay, and from the vegetable mould, half covered with flints, to the rich homogeneous soil called *terre de Beauce*, which is considered the most productive, and covers 194,790 acres. The flinty soils, amounting to 111,626 acres, are best adapted for vine culture. All the land capable of cultivation is tilled, but agriculture is in a backward state.

The department takes its name from the river *Indre*, which rises just within the department of Creuse, and entering that of Indre flows N.W. past Sainte-Sévère, La-Châtre, Châteauroux, and Châtillon, below which it enters the department of Indre-et-Loire; here passing Loches, where it becomes navigable, it continues in the same direction as far as Montbazou, and then turning W. passes Azay-le-Rideau, below which it enters the Loire between the embouchures of the Creuse and the Vienne. Its whole length is 124 miles, of which 44 are navigable; its mean width 98 feet, and its ordinary depth from 5 to 6 feet. It is subject to floods, which rise from 10 to 11 feet at their highest, and spreading beyond the banks sometimes do great damage, but add largely to the fertility of the soil. The number of mills along the banks of this river is considerable. The south and south-west of the department is drained by the Creuse and its feeder, the Anglin, which is itself increased by the Abloux. [CREUSE.] The west of the department is drained by the *Claise*, a feeder of the Creuse, which flows through the marshy district of Brenne; and the east and north are drained by feeders of the Cher, namely, the *Aron*, which receives the Théols, and the *Fouzon*, fed by the Nahon.

The department is crossed by a railroad, which branches off from the Orléans-Bourges line at Vierzon, and runs through Issoudun to Châteauroux.

Products.—Wine and corn are produced in quantity more than enough for the consumption; buck-wheat, hemp, flax, chestnuts, and fruits are also grown. The annual produce of wine is 6,600,000 gallons, about one-half of which is exported. Although the pasture land is of no great extent, yet considerable numbers of horned cattle are kept; hay is saved for their winter food, and in summer the scantiness of the pasture is eked out with the leaves of trees, especially with those of the elm. Sheep are a source of great profit to the farmer, on account of the fineness of their wool; the quality of the wool of the *Champagne* district especially is very superior. The sheep are very carefully tended; ewes, lamb-hogs,

and wethers, are kept in separate flocks, each under its own shepherd: they are never folded; when the winter is severe, they get a mixture of hay and straw three times a day. Great numbers of geese and turkeys are reared, and also of mules, pigs, and horses. The climate is mild and healthy, except in the Brenne district, where the atmosphere is almost always charged with pestilential fogs.

Several iron mines are worked; marble, millstone, limestone, mica, flint, lithographic stones (the best in France), granite, quartz, spar, marl, potter's clay, variegated marbles, &c., are found.

The cloth manufactures of Châteauroux and some other places are important; linen, hosiery, scythes, paper, porcelain, and earthenware are made. There are also numerous establishments for the manufacture of woollen yarn, leather, beer, parchment, &c. There are important iron-works at Clavières. The commerce of the department is composed of the various agricultural and industrial products named. About 340 fairs are held in the year, principally for the sale of sheep.

Divisions and Chief Towns.—There are four arrondissements, which, with their subdivisions and population, we here enumerate:—

Arronds.	Cantons.	Communes.	Pop. in 1863.
Châteauroux,	8	81	102,212
Le-Blanc, .	6	56	59,086
Issoudun, .	4	49	51,836
La-Châtre, .	5	59	56,920
Total, .	23	245	270,054

Of the arrondissement of Châteauroux and of the whole department, the capital is CHATEAUX-ROUX. *Argenton-sur-Creuse*, 16 miles S. by W. from Châteauroux, is built on both banks of the Creuse, and consists of an upper town, which grew up round an ancient castle now in ruins, and of a lower town, joined to the former by a stone bridge. The most remarkable structures now remaining in the upper town, which is entered by four gates, are the Gate of Auditory, now used as a prison, and the desecrated church of St. Benoît, now used as the corn market, on the roof of which are still seen the arms of Louis de Bourbon, count of Vendôme. Linen, cloth, tiles, bricks, woollen yarn, paper, leather, &c., are manufactured in the town, which has 4765 inhabitants. *Ardentes-St.-Martin*, on the left bank of the Indre, has 2561 inhabitants, who manufacture scythes and tools. *Bourg-Dieu* or *Déols*, formerly a large town, and the capital of Lower Berri, now a village of 2415 inhabitants, stands about a mile N. of Châteauroux. It was celebrated for its Benedictine Abbey, whose suppression by Gregory XV., in 1623, caused the decay of the town. Of the vast buildings of the abbey, only a single tower is now standing; the magnificent ruins which remained till 1830 were then sold and removed as materials for building. *Buzançais*, prettily situated 13 miles W. of Châteauroux on a hill on the right bank of the river Indre, which is here crossed by five bridges, is an ill-built town with 5016 inhabitants. It possesses extensive cloth manufactories. There are several flour mills

in the town, and in the environs large iron-works. *Châtillon-sur-Indre*, formerly an important fortress on the frontiers of Berri, is built on a height crowned by the ruins of an ancient castle, near the left bank of the Indre, 26 miles N.W. from Châteauroux, and has 2869 inhabitants. The church is a large and handsome structure, which dates from the tenth century, and contains some remarkable sculptures. In the principal street stands an ancient house, on whose front are figures of Momus and a player on the pipe. From the market-place there is a fine view of the valley of the Indre. *Levroux*, the ancient *Gabatum*, stands on the Nahon, 12 miles N. from Châteauroux, and has 3867 inhabitants, who manufacture cloth and leather, and deal in corn, wine, wool, and cattle. The parish church of Levroux is considered the finest in all Lower Berri. Several Roman remains and Celtic coins have been found in and near this town, some of the fortifications of which still remain. *Valençay*, farther N. on the left bank of the Nahon, has a population of 3587, and manufactures of hosiery, cloth, cutlery, and fine woollen yarn. The great ornament of Valençay is the magnificent château, or rather palace, built in the reign of Francis I. by the family of Etampes; it is surrounded by a large park, diversified by beautiful gardens and waterworks. This château was the prison of Ferdinand VII., king of Spain, from 1808 to 1814; it was the property of Talleyrand, who for some time made it his residence.

In the arrondissement of Le-Blanc, the chief town, *Le-Blanc*, is beautifully situated on the Creuse, here crossed by a handsome bridge, above which the river expands so as to form a lake, and below it breaks into cascades, generating force to drive the machinery of several factories. The town is improving, and has considerable cloth factories, vinegar works, potteries, a linen-yarn mill, a large brewery, and several iron forges and smelting furnaces. It is the seat of a tribunal of first instance, and has a savings' bank, and 5882 inhabitants, who trade in wine, fish, timber staves, and the articles named before. *Bélâbre*, S. by E. of Le-Blanc, on the right bank of the Anglin, has 2221 inhabitants, and some remains of an ancient castle. *Mezières-en-Brenne* has 1681 inhabitants; it stands N. by E. of Le-Blanc, on the right bank of the Claise, in a district not long ago an unapproachable marsh, but now drained, planted, and well cultivated. There is a remarkable church here, which was dedicated in 1339 to Sainte-Marie-Madeleine, and contains many mementos of the family of Anjou. *St.-Gualtier*, E. of Le-Blanc, on the Creuse, which is here passed on a suspension bridge, has an ecclesiastical college, and a population of 1902.

In the arrondissement of Issoudun, the chief town, *Issoudun*, is situated partly on the slope, and partly at the foot of a hill above the river Théols, which is here crossed by three bridges, leading to as many suburbs, in $46^{\circ} 56' 54''$ N. lat., $2^{\circ} 0' 49''$ E. long., at a distance of 17 miles by railway N.E. from Châteauroux, and has 14,282 inhabitants. The older part of the town, called Le Château, has very good houses, but the streets are dirty, narrow, and tortuous; the rest of the town is better built, having

been constructed since the terrible conflagration of 1651, which broke out at a time when the city was assaulted by the army of the Fronde, and by which 1200 houses were destroyed. The town has tribunals of first instance and of commerce; a consultative chamber of manufactures, and a communal college. Woollen cloth and yarn, calico, hosiery, parchment, leather, and beer are the principal industrial products; there are some bleaching establishments also, and a good business is done in the articles enumerated, and in corn, wine, wool, cattle, wood, timber, iron of superior quality, &c. There are four churches, two hospitals, and a town-hall. *Vatan*, which stands 13 miles N.W. of Issoudun, has an ancient church dedicated to St.-Laurian, and rebuilt in 1005: population, 3047. *Reuilly*, 9 miles N. by railway from Issoudun, stands near the Théols, and has 2568 inhabitants. In the town stands a remarkable structure in the Renaissance style, which is called La Grande-Maison; and in the environs is the splendid residence of Ferté-Reuilly, built by Mansard in 1659 for Jacques de la Fond. An ancient Gothic church stands half a mile S. of the town, on the hill of Vergy, the summit of which was formerly crowned by a strong fortress.

In the arrondissement of La-Châtre, the chief town is *La-Châtre*, which stands in the most fertile and picturesque part of Berri, on a hill that skirts the Indre on one side, and overlooks on the other a deep narrow valley laid out in gardens and orchards. It is situated in $46^{\circ} 34' 53''$ N. lat., $1^{\circ} 59' 4''$ E. long., 19 miles S.E. from Châteauroux, and has a tribunal of first instance, a college, and 5038 inhabitants. The streets are well but not regularly built, yet the town makes an agreeable impression from the charming scenery which is presented to view from almost every point. The most remarkable structures are the church and two ancient wooden houses. Woollen cloth and leather are manufactured; there is also a considerable trade in wool, goat skins, feathers, cattle, and chestnuts (of which large quantities are grown in the neighbourhood). *Aigurande*, S. of La-Châtre, has a population of 2146. *Neuwy-St.-Sépulchre*, said to occupy the site of the ancient *Noviiodunum*, is 8 miles W. of La-Châtre, and has a population of 2175. *Sainte-Sévère*, formerly a strong fortress, now a village of about 1000 inhabitants, stands near the Indre, 6 miles S.S.E. from La-Châtre. Of its formidable defences, which, when in the possession of the English, were with great difficulty mastered by Du Guesclin, only a single tower remains.

The department forms, together with that of Cher, the see of the archbishop of Bourges; it is comprised in the jurisdiction of the Cour Royale and University Academy of Bourges, and belongs to the fifteenth Military Division, of which Bourges is head-quarters. It returns two members to the Chamber of Deputies.

(*Dictionnaire de la France; Statistique de la France; Richard, Guide Classique du Voyageur en France; Annuaire pour l'An 1866; Malte Brun and Lavallée, Géographie Universelle.*)

INDRE-ET-LOIRE, a department in France, formed out of the old province of Touraine, is bounded N. and N.E. by the departments of Sarthe

and Loir-et-Cher, E. and S.E. by those of Loir-et-Cher and Indre, S. by those of Indre and Vienne, and W. by those of Vienne and Maine-et-Loire. It lies between 46° 43' and 47° 42' N. lat., 0° 5' and 1° 18' E. long.; its greatest length from N. to S. is 68 miles, from E. to W. 55 miles. The area is 236 square miles, and the population in 1863 was 323,572.

The department takes its name from the INDRE, noticed in the preceding article, and the LOIRE, which crosses it from E. to W. The other rivers which ultimately or directly enter the Loire on the left bank are the CHER, which throws off several arms to the Loire, forming islands before its main stream enters that river; the Claise, which crosses the southern angle of the department [INDRE]; the CREUSE, which forms part of the south-western boundary; and the VIENNE, which enters this department at the point where it is joined by the Creuse, and, flowing in a north-western course past Chinon, enters the Loire on the extreme western boundary of the department. On the right bank, the feeders of the Loire in this department are the Brenne and the Doit. The Doit rises in a pond W. of Savigné; flowing S. past Bourgueil, it turns W., and, under the name of Authion, runs for the distance of forty miles parallel to the Loire, which it enters in the centre of the department of Maine-et-Loire at St.-Aubin-des-Ponts-de-Cé, S. of Angers. Except the Brenne, the Doit, and the Claise, all the rivers mentioned are navigable. The department is traversed by the Orléans-Tours Railway and its branches.

The Loire and its principal feeders are subject to great inundations, which frequently do incalculable damage to property on their banks. One of the most disastrous overflows of this kind on record occurred in October 1846, when in one night the Loire rose 20 feet, and continued to rise for two days, sweeping away bridges and viaducts, and destroying many lives, and property to the amount of about 2,000,000*l.* sterling. On ordinary occasions such disasters are prevented by the enormous dykes that line both banks of this great river from the neighbourhood of Blois to the mouth of the Authion before mentioned, a distance of ninety-three miles. The dykes are 22 feet wide on the top, and so high as to intercept the view of the low grounds from passengers by the steamers that ply on the river; the parts most exposed to the flood are faced with uncemented masonry. The high road runs along the summit of the dyke on the right bank, and presents one of the finest drives in the world, curtained with poplars and diversified by the views of villas, towns, populous villages, and those curious dwellings hollowed out in the sides of the rocky hills that now and then approach the right shore.

Surface.—To the north of the Loire the surface of the department is hilly, and presents three extensive forests and several vast and barren wastes. The cultivation here is still rude, and the population scanty. Along the banks of the Loire, however, a very different landscape is presented; well-cultivated fields, luxuriant pastures and meadows, vineyards and orchards, attesting equally the fertility of the deep alluvial soil and the industry of the inhabitants. Between the Indre and the Vienne occurs a re-

markable table-land, containing an immense deposit of fossil shells, which are used as manure. The great forests south of the Loire are those of Amboise, Loches, and Chinon. On the slopes surrounding the forest of Amboise grow the vineyards that yield the rich Cher wines. In general, the surface in this portion of the department presents strong deep wheat soils, rich pastures, vineyards, and orchards; there are, however, some barren wastes here as well as north of the Loire, but they are comparatively of small extent. Large tracts are covered with heath and broom (*genêt*), the latter the plant which, it is said, originated the name of our great English dynasty of Plantagenet. The inundations of the rivers add greatly to the fertility of the soil. The climate generally is mild.

Products.—The valleys of the Loire and the other principal rivers in this department contain some of the most productive and best cultivated land in France. All kinds of breadstuffs are produced in quantity more than enough for the consumption. One of the most important products is wine, of which 14,000,000 gallons are made in ordinary years; next come hemp, walnuts for making oil, plums, beans, leguminous plants, liquorice, anise, and coriander; citrons, melons, almonds, apples, pears, truffles, &c. Bees and silkworms are carefully tended: game and fish are abundant.

Iron mines are worked; stone, especially a tuffaceous sandstone, of which most of the houses are built, is quarried out of the hills near the Loire, and excavations thus formed are occupied as dwelling-places by the poorer inhabitants. Millstone grit, marl, lithographic stones, pipe and potter's clay, and brick-earth are found. Copper ore is met with, but no mines are worked.

The chief industrial products are bar iron, powder, and files; woollen cloth, of which manufacture Tours is the centre; silk, leather, paper, and pottery are also made, but the manufacture of the three latter articles is not so important as formerly. The culture of silk is increasing, as are the silk, linen, and woollen manufactures of Tours. There is a national gunpowder factory and nitre refinery at Montbazou. About ninety fairs for the sale of cattle and agricultural produce are held. Druidical or Celtic remains are numerous in this part of France.

Divisions and Chief Towns.—The department contains three arrondissements, which, with their subdivisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1863.
Tours, . .	11	126	169,232
Chinon, .	7	87	89,407
Loches, .	6	68	64,933
Total, .	24	281	323,572

In the arrondissement of Tours, the chief town, *Tours*, which is also the capital of the department, stands on the south bank of the Loire, in a plain that lies between that river and the Cher, in 47° 23' 46" N. lat., 0° 41' 24" E. long., sixty-five miles by railway S.W. from Orléans, and in 1861 had 41,061

inhabitants. Tours, as well as Touraine, takes its name from the *Turones*, a Celtic tribe, of whose capital, *Cæsarodunum* or *Cæsaromagus*, it occupies the site. The entrance to the city from the Paris road is striking; a magnificent stone bridge of fifteen arches, 475 yards in length, and sixteen yards wide, leads across the Loire into a spacious square, formed by the wide river on the northern side, the fine buildings of the town-hall and the museum on the south, while the east and west sides are formed by two terraces planted with trees. Passing through the square, a straight wide street (*Rue Royale*) is entered, consisting of houses built in good taste and on a uniform plan; this street, which is furnished with foot-pavements, runs right across the town in its widest part, and terminates in the avenue of Grammont, at the end of which a bridge crosses the Cher into the Poitiers road. The other streets are, with few exceptions, ill-built, narrow, and crooked. There are several suburbs, but these can scarcely be distinguished from the town itself, as it has no ramparts except on the side next the Cher, and these are laid out so as to form the fine promenade called *Le-Mail*. The wide quays along the Loire, which is joined to the Cher by a canal, are a great ornament to the town; they extend on each side of the bridge, are planted with trees, and backed by large buildings. Tours is the terminus of railways from Paris, Bordeaux, and Nantes. The most remarkable structures are—the cathedral, in the Gothic style of architecture, built by Henry V., of England, and dedicated to St.-Gratien, the first bishop of Tours, the portal of which contains a magnificent rose window, and is surmounted by two towers 263 feet in height, and terminating in domes; the cavalry barracks, built on the site of the English Henry II.'s castle, of which only a single tower now remains; two lofty towers in the *Rue St.-Martin* (one containing a clock, and hence called *Tour d'Horloge*, and the other called *La Tour de Charlemagne*, from the belief that Charlemagne's queen was buried beneath it), which are the only remains of the great cathedral of St.-Martin-de-Tours, founded by St.-Martin; the churches of St. Clement and De-la-Riche; the fountain of Beaune, which stands in the market-place, and consists of an octagonal basin filled with water, gushing in four jets from a central pyramid adorned with sculptures and arabesques; the episcopal palace; the court-house; the college buildings; the general hospital; and the residence of the prefect, which also contains a public library of 40,000 volumes and several valuable manuscripts. Tours has a tribunal of first instance, a tribunal and chamber of commerce, one communal and two ecclesiastical colleges, a botanic garden, and several literary and scientific societies. The chief manufactures are woollen cloth, silk stuffs (in which an important trade is carried on), ribands, serge, carpets, small wares, wax candles, woollen yarn, leather; the commerce is composed of these articles and of corn, wine, brandy, plums and dried fruit, hemp, wool, &c. Tours had in the middle ages one of the most important mints in France, in which were coined the *livres tournoises*, often named in history, and each worth a franc. There is here a large printing establishment, which has produced some very fine works—especially Gustave

Doré's 'Illustrated Bible.' In one of the suburbs, called Riche, stood the castle of *Plessis-les-Tours*, in which Louis XI. died, and which has been rendered famous by Sir Walter Scott's novel of 'Quentin Durward'; the keep is the only part of the edifice now standing. The intolerance of Louis XIV. greatly diminished the population of Tours, by driving most of the Huguenots away. Many of them were silk-weavers, who emigrated to England and settled in Spitalfields. At Mettray, near the town, is a voluntary establishment for the reformation of juvenile offenders, which has deservedly acquired great repute. The city of Tours has always been a favourite abode with the English, and contains a large number of good houses. The other towns are AMBOISE, the castle of which was the prison residence of Abd-el-Kader; *Bléré*, a busy little town of 3477 inhabitants, on the left bank of the Cher, which is here crossed by a bridge built by Henry II., of England; *Château-la-Vallière*, in the N.W. of the department, which has iron forges and 1309 inhabitants; *Château-Renault*, which stands on the slope and at the foot of a hill in a pretty country on the Brenne, and has 3562 inhabitants, who manufacture cloth, flannel, leather, and tiles; the town is named from an old castle built in the year 981, and still standing; *Montbazon*, a small place on the right bank of the Indre, with a population of only 1074, but important for the great powder-mills and saltpetre-works near it; and *Vouvray*, which is situated seven miles E. from Tours on the railway to Orleans, and on the Loire, in a district famous for its white wine, and has 2438 inhabitants.

In the arrondissement of Chinon, the chief town, *Chinon*, is built on the Vienne, at the foot of a hill, the summit of which is covered with the ruins of the ancient fortress of Chinon, where Henry II. died, and Joan of Arc had her first interview with Charles VII. It is twenty-five miles S.W. from Tours, and has a tribunal of first instance, a college, savings' bank, and 6905 inhabitants, who manufacture serge, drugget, haircloth, earthenware, saltpetre, &c., and trade in cattle, corn, wine, brandy, plums, nut-oil, honey, wax, &c. Chinon is an improving town; the old ramparts are now replaced by quays. Rabelais was born here in 1483. *Azay-le-Rideau*, prettily situated on the Indre, about five miles above its junction with the Loire, is remarkable for a fine structure called *Château-d'Azay*, built on an island in the Indre; the town has 2073 inhabitants. *Bourgueil*, situated in a very fertile district on the right bank of the Doit, at a distance of ten miles N. from Chinon, has a college, and 3416 inhabitants, and a trade in wine. *Cinq-Mars*, on the left bank of the Loire, near Langeais, is a small place of only 1999 inhabitants. It deserves notice on account of its ancient square tower, which is built of bricks, perfectly solid, ninety feet high, thirteen feet wide on each face, and surmounted at the angles by four pinnacles, each eleven feet high; a central pinnacle was thrown down by a storm in 1571. The purpose and date of its erection are unknown. *Langeais*, eighteen miles N.N.E. from Chinon, stands on the right bank of the Loire, and has 3381 inhabitants, who trade in agricultural produce and manufacture linen, tiles, bricks, and earthenware. The castle in

which Charles VIII. espoused Anne of Brittany is still in tolerable preservation. *Sainte-Maure* stands on the right bank of the Manse, eighteen miles E. from Chinon, and has 2595 inhabitants, who manufacture linen, printed calicoes, and haircloth. The church of Sainte-Maure is one of the finest in Touraine; it dates from the twelfth century, and beneath it there is a crypt still more ancient. *Richelieu*, a well-built town, consisting of several wide straight streets that terminate in a handsome square in the centre of the town, stands 11 miles S. from Chinon on the Mable, and has 2601 inhabitants, who manufacture beet-root sugar and brandy, and have a considerable trade in wine and fruits, and other agricultural produce. Cardinal Richelieu erected a residence in this (his native) town in 1637, and the place was then built on a regular plan; the cardinal's palace is now a heap of ruins.

In the arrondissement of Loches, the chief town, *Loches*, stands on the left bank of the Indre, at a little distance from *Beaulieu*, a suburb of about 1800 inhabitants, to which it is joined by several bridges thrown across the arms of the river. The town is 24 miles S. by E. from Tours; it is built round the base of a hill, the summit of which is crowned by the remains of its ancient castle. The situation of Loches, in the rich and beautiful valley of the Indre, and the historical associations connected with it, render it one of the most interesting towns in Touraine. A great part of the castle, in which several of the kings of France resided, and which also served as a state prison for illustrious political offenders, is now in ruins. The keep is still used as a prison, and in a more modern portion the sub-prefect resides. Between the keep and the residence of the sub-prefect is the church of St.-Ours, which has a stone roof surmounted by two lofty pyramidal spires; the tomb of Agnes Sorel, mistress of Charles VII., is in this church. At a short distance from the town, and near the forest of Loches, which supplies mast timber to the French navy, are the ruins of the Carthusian convent of *Liget*, founded by Henry II. in expiation of the murder of Becket. The town of Loches presents narrow streets and ancient houses; it has a tribunal of first instance, a college, and 5267 inhabitants, who manufacture linen, coarse cloth, woollen yarn, leather, and paper. *La-Haye-Descartes*, the birth-place of Descartes, is prettily situated on the right bank of the Creuse, and has 1620 inhabitants. *Ligueil*, W. of Loches, stands on the Estrigneuil, a feeder of the Creuse, and has 1992 inhabitants, who grow great quantities of plums. *Le-Grand-Pressigny*, on the right bank of the Claise, with a population of 1809, and the ruins of a castle of the thirteenth century; and *Preuilly*, further south on the same bank, which has iron forges and 2194 inhabitants, give names to cantons.

The department forms the see of the archbishop of Tours, is included in the jurisdiction of the Cour Royale and University Academy of Orléans, and belongs to the eighteenth Military Division, of which Tours is head-quarters. It returns three members to the Chamber of Deputies.

INDUCTION (Mathematics). The method of induction, in the sense in which the word is used in natural philosophy, is not known in pure mathematics. There certainly are instances in which a general proposition is proved by a collection of the demonstrations of different cases, which may remind the investigator of the inductive process, or the collection of the general from the particular. Such instances, however, must not be taken as permanent, for it usually happens that a general demonstration is discovered as soon as attention is turned to the subject.

There is, however, one particular method of proceeding which is extremely common in mathematical reasoning, and to which we propose to give the name of *successive induction*. It has the main character of induction as defined by the logicians, because it is really the collection of a general truth from a demonstration which implies the examination of every particular case; but it differs from the process of physics inasmuch as each case depends upon one which precedes. Substituting, however, demonstration for observation, the mathematical process bears an analogy to the experimental one, which, in our opinion, is a sufficient justification of the term 'successive induction.' An instance of the method will enable the mathematical reader to recognize a mode of investigation with which he is already familiar.

Example.—The sum of any number of successive odd numbers, beginning from unity, is a square number, namely, the square of half the even number which follows the last odd number. Let this proposition be true in any one single instance; that is, n being some whole number, let $1, 3, 5, \dots$ up to $2n + 1$ put together give $(n + 1)^2$. Then the next odd number being $2n + 3$, the sum of all the odd numbers up to $2n + 3$ will be $(n + 1)^2 + 2n + 3$, or $n^2 + 4n + 4$, or $(n + 2)^2$. But $n + 2$ is the half of the even number next following $2n + 3$: consequently, if the proposition be true of any one set of odd numbers, it is true of one more. But it is true of the first odd number 1, for this is the square of half the even number next following. Consequently, being true of 1, it is true of $1 + 3$; being true of $1 + 3$, it is true of $1 + 3 + 5$; being true of $1 + 3 + 5$, it is true of $1 + 3 + 5 + 7$, and so on, *ad infinitum*.

INDUCTION (Gr. *epagoge*), as defined by the late Archbishop Whately, 'is a kind of argument which infers respecting a whole class what has been ascertained respecting one or more individuals of that class.' According to Sir William Hamilton, the word has been employed to designate three very different operations:—1. The objective process of investigating particular facts, as preparatory to Induction, which he observes is manifestly not a process of reasoning of any kind; 2. A material illation of a universal from a singular, as warranted either by the general analogy of nature or the special presumptions afforded by the object matter of any real science; 3. A formal illation of a universal from the individual, as legitimated solely by the laws of thought and abstracted from the conditions of any particular matter. The second of these operations is the inductive method of Bacon, which proceeds by means of rejections and conclusions, so as to

arrive at those axioms or general laws from which we may infer by way of synthesis other particulars unknown to us, and perhaps placed beyond reach of direct examination. ('Nov. Org.,' 'Aph.,' c. iii. c. v.) Aristotle's definition coincides with the third, and induction 'is an inference drawn from all the particulars.' ('Prior. Anal.,' ii. c. xxiii.) The third alone is properly an induction of logic; for logic does not consider things, but the general forms of thought under which the mind conceives them; and the logical inference is not determined by any relation of causality between the premiss and conclusion, but by the subjective relation of reason and consequence as involved in the thought. The inductive process is exactly the reverse of the deductive; for while the latter proceeds from the whole to the part, the former ascends from the part to the whole: since it is only under the character of a constituted or containing whole, or as a constituent and contained part, that anything can become the term of logical argumentation. Of these two processes Professor Hamilton gives the following figures:—

Induction.	Deduction.
X Y Z are A.	B is A.
X Y Z are whole B.	X Y Z are under B.
∴ whole B is A.	∴ X Y Z are A.
Or,	Or,
A contains X Y Z.	A contains B.
X Y Z contains B.	B contains X Y Z.
∴ A contains B.	∴ A contains X Y Z.

INDUCTION. [ADWOWSON; BENEFICE.]

INDULGENCE is a power claimed by the Roman Catholic Church of granting to contrite and confessed sinners 'a remission of the temporal punishment which often remains due to sin after its guilt has been remitted.' According to their catechism, it is not in any sense a pardon of the guilt of sin, whether past, present, or future; but it always supposes that the guilt has already been removed before its benefit can be applied to the soul. There are two kinds of indulgences—plenary and partial. By a plenary indulgence is meant the remission of the whole debt of temporal punishment due to sins, and by a partial indulgence a part of that debt. If, for instance, a man had gained for his own benefit a plenary indulgence, he would go straight to heaven without passing through purgatory; but if he had only gained a partial indulgence, he would have to expiate the rest of his debt in purgatory. We may observe that indulgences are granted in some cases to those who give money for the building of churches and other pious purposes, but that the sale of or traffic in indulgences has been severely reprobated by many councils. 'An indulgence,' say they, 'being the remission of the temporal punishment which remains *after* the guilt has been remitted, necessarily presupposes a state of grace. Nay, so perfect must be this condition in the case of a plenary indulgence, that it requires a freedom from the guilt not only of mortal but also of venial sin. For so long as there remains on the soul the least venial sin unforgiven, the temporal punishment due to that sin cannot be remitted, and consequently the full benefit of a plenary indulgence cannot be obtained.' Protestants generally regard the doctrine of indulgences as being founded not only on an

unwarranted assumption of power given to the church, but also on a doctrine of human works and merits inconsistent with what scripture teaches as to the office of Christ as a Saviour. The wholesale disposal of indulgences in the papacy of Leo X. excited the indignation of Luther, and was one of the primary causes of the Reformation.

INDUS (the Indian), a constellation of Bayer, situated between Sagittarius and the South Pole.

INDUS. [HINDUSTAN.]

INDUSTRIAL EXHIBITIONS. Since the great International Exhibition of London, 1862, various efforts have been made to gather together the productions of amateur artists, whose daily life is spent in business or manual labour, and to exhibit these collections to the public, at such a price as will pay the expenses, and leave a surplus for distribution in prizes to the exhibitors. The objects aimed at have been to bring to light the latent talent of the industrial classes, to give them opportunities of wider culture and loftier aims, and to stimulate them to make the best use of their leisure hours. Industrial Exhibitions were held in various parts of the metropolis during the years 1864–65, and at Birmingham, Glasgow, Bristol, Nottingham, and many other provincial towns, in 1865, all of which were attended with complete success. All classes of society, from the queen to the poorest operative, have taken an interest in them, which has resulted in the cordial co-operation of different classes one with another, and offered great inducements to working men to exert themselves in raising their social position.

INEQUALITY. (Astronomy.) For the sake of convenience, the average motion of a planet or satellite, supposed to be made in a circle which has the average distance of the body from the sun or primary for its radius, is the first object of calculation when the place of the body at some future time is to be predicted. All the alterations which are rendered necessary by the unequal motion of the planet are called inequalities.

INERTIA. This word means something equivalent to the modern English sense of inactivity, and expresses that universal property of matter by which it does not change its state either of rest or motion, unless acted upon by some external force. The former part of this principle was known to the ancients, but Galileo demonstrated that the latter was equally true and general. This property of matter has been called by Kepler *vis inertiae*.

INFALLIBILITY OF THE CHURCH. The church of Rome claims to be infallible in her teaching as to faith and morals, asserting that she is assisted by the Holy Spirit in understanding the extent and meaning of the revealed truth of God, so that she cannot propose any doctrine as true which is false, nor condemn any doctrine as evil which is in reality good. Roman Catholics base this claim on several passages of scripture, but most especially on those which occur in Matt. xvi. 18; xxviii. 20; and John xiv. 16. They also argue that it is absolutely necessary for the church to be infallible, or otherwise there could be no safety as to the truth or falsehood of any new doctrine which might be proposed. They do not consider the pope infallible as a private person, and some not even as regards his official capacity as an individual; but all agree

that the power resides in the collective decisions of the bishops of the church, acting with the pope, when assembled as a general council. The infallibility claimed only extends, as above stated, to questions of faith and morals, and does not embrace questions of science, or matters of fact, or abstract opinions, unconnected with religion.

The Greek church claims infallibility for the decrees of the councils which she looks upon as œcumenical, and inerrancy, or actual exemption from error, for her teaching up to the present time.

The principal Protestant objections to the doctrine of infallibility are—that the texts quoted by Catholics only teach the permanence of the church and the continuance of God's grace towards it, and have no relation to the special subject of infallibility; that the doctrine invalidates any argument from scripture; and that it is nothing less than reasoning in a circle to first attempt to prove the infallibility of the church from the Bible, and then the authority of the Bible by the infallibility of the church. It is also argued that the advocates of the doctrine have never yet even been able to agree as to whether the pope is infallible.

INFAMY (from the Roman *infamia*), in English law, is not easily defined. Conviction and sentence for certain offences formerly rendered a person infamous, and incompetent to be either a juror or a witness. But endurance of the punishment, or reversal of the sentence, restored his competency. This principle, though once among the most settled peculiarities of English law, has been modified by recent Acts of Parliament. The 9 Geo. IV., c. 23, s. 3, enacts that where a man convicted of a felony shall have undergone the legal punishment for it, the effect shall be the same as a pardon under the Great Seal; and by s. 4, no misdemeanour, except perjury or subornation of perjury, shall render a man an incompetent witness after he has undergone his punishment. The 6 & 7 Vict., c. 85, enacts that no man shall be excluded from giving evidence, either in person or by deposition, on any issue or inquiry, civil or criminal, though he may have been previously convicted of any crime or offence; and by 14 & 15 Vict., c. 99, even the parties to a cause shall be competent and compellable to give evidence on behalf of either or any of the parties, unless the question tends to criminate the person examined. (Stephens' *Commentaries*, 5th ed. III. 634.)

Certain offences enumerated in 7 & 8 Geo. IV., c. 29, s. 9, are infamous crimes with reference to the provisions of that Act.

Infamy, though it does not disqualify, may still be urged as an argument against the credibility of a witness. But the infamy must be that proceeding upon conviction, not that resulting from general bad character.

The only satisfactory definition of infamy would be a permanent legal incapacity to which a man is subjected in consequence of conviction for an offence, and which is not removed by suffering the punishment annexed to it. By 2 Geo. II., c. 24, s. 6, persons who have been legally convicted of perjury, or subornation of perjury, or of taking and asking any bribe, are for ever incapacitated from voting at the election of members of Parliament. Having thus lost part of their political rights, they are regarded as infamous in the eye of the law.

The law of Scotland has been assimilated to that of England by the Acts 1 Will. IV., c. 37, s. 9, and 15 Vict., c. 27, s. 1; and the objection of infamy as a ground of excluding a witness is thus altogether abolished. But as in England, infamy may be inferred by the commission of certain offences, such as falsehood, forgery, perjury, theft and reset, and all capital crimes.

Infamia, in Roman law, was the consequence of any serious diminution of a man's *existimatio* or reputation. It was either *infamia juris*, infamy resulting from condemnation for certain heinous crimes, or from an infamous action or trade; or *infamia facti*, arising from an immoral course of life. What was called *levis nota* was a lesser degree of infamy, and attached to freedmen and the children of actors. Its only consequence, however, was to induce certain civil disabilities. The law on the subject is chiefly contained in the Digest III., tit. 2; Savigny, 'System des Heut. Röm. Rechts,' II., s. 76-83; Mackeldy, 'Comp. of Modern Civil Law,' II. 3, s. 123.

INFANT, a person under the age of twenty-one. He has various privileges and disabilities. An infant cannot be sued as a general rule save under the protection and joining the name of his guardian, that is, his guardian *ad litem*, appointed by the court for the purpose of the particular suit; and on the other hand they may sue by their next friend. The exception to this rule is made by the County Courts Act, where an infant may sue for wages not exceeding 20*l.*; he may bind himself to pay for his necessary meat, drink, apparel, physic, and such other necessities, and for his good teaching and instruction; and in determining what are necessities, regard is had to the infant's degree or station in life. He is also liable for such necessities as are supplied to his wife and family, but not for goods supplied to him while living unmarried under the roof of his parent. Infants lose nothing during their minority by non-claim or neglect of demanding their rights. They cannot make any conveyance or purchase that will bind them, nor enter into a binding contract, nor do any legal act, nor hold any public office of pecuniary trust, or any office of a judicial kind; but a contract entered into during infancy is voidable rather than void, because it may be confirmed by the infant when he becomes of age; and again, he may always act as the agent for another person, and may bind himself apprentice, and he may present, having an advowson, to the benefice when it becomes void.

In criminal cases, a person of the age of fourteen years may be capitally punished for a capital offence, but under the age of seven he cannot. At fourteen he may enter into a binding marriage, and a female may do so at twelve years of age. An infant is also answerable in an action brought against him for slander, battery, or trespass on land. Infants cannot be members of Parliament.

INFANT SCHOOLS. [SCHOOLS.]

INFANTA, INFANTÉ, the titles of the princesses and princes of the royal houses of Spain and Portugal. The latter is seldom used, as the heir-apparent to the throne in Spain is styled Prince of Asturias, and the heir-apparent in Portugal was styled the Prince of Brazil, till the separation of that country from Portugal in 1822.

INFANTICIDE, the practice of putting infants to death, or exposing them, has existed from the earliest ages. The exposure of infants was common to all the Grecian states, with the exception of Thebes; and amongst the Romans prevailed from the time of Romulus to that of Valentinian I. We have proof of the existence of the practice of putting infants to death among the Persians, Phoenicians, Carthaginians, Peruvians, and Mexicans. In China, throughout almost every part of the empire, a large proportion of the female population are put to death as soon as they are born. One traveller, Mr. Abeel, states that in some provinces not one female infant out of three is suffered to live; and that in others the difference between the male and female population is one to ten. Lord Macartney estimated the annual mortality in Peking at 20,000; while Gibbon, on the authority of Le Comte, limited it to 3000. Amongst the Hindus, from the difficulty of providing marriage portions for their daughters, the custom, which has existed for two thousand years, prevailed to a very great extent, till the Marquis of Wellesley, when Governor-general of India, used every possible exertion to put a stop to it. His efforts, however, appear to have been only temporarily successful, and female infanticide is still practised in the Sooradah and Jeypore districts of Khordistan, while the murder of male children still lingers among the remote hills of Chinnah Kimedry. During the middle ages, it is stated by the Jesuit Gaspar Vilela to have existed in Japan, but at the present day it is much decreased, the peculiar legislation of that country in regard to prostitution rendering it no longer necessary. Among the Mohammedans the practice is not discountenanced, though greatly lessened by the habit of producing abortion. Strabo tells us that it was unknown to the ancient Egyptians, and Tacitus says the same of the Germans. No traces of it have as yet been discovered among any of the early British tribes. It has been found among the native septa of Brazil, in Otaheite, the South Sea and Sandwich Islands, to a fearful extent; also in New Zealand, New South Wales, South Africa, and even in Hudson's Bay, Labrador, and Iceland.

Among the ancient and heathen nations infanticide appears as a *practice*, not as a *crime*. In the countries again where Christianity prevails, child-murder has ever been regarded with the deepest abhorrence, and visited with the extreme severity of the law. Amongst the Germanic nations of the Middle Ages the punishment of death was appended to the murder of a new-born child, and the same rule held good in Lombardy and Saxony. In France a well-known Act of Henry II., passed in 1556, punished with death, as presumably guilty of the murder of her child, every woman convicted of concealment of pregnancy. This law prevailed till 1791, when this very unjust presumption was repealed; but the punishment of death still continued for the murder of the child. The statute of Henry II. was adopted in England by the 21 Jac. I., c. 27, and by 6 Anne, c. 4, was extended to Ireland. Both of these were afterwards rescinded, and the law is now fixed by 24 & 25 Vict., c. 100, s. 60. The alterations which this Act made on the law may be said to consist in this: that whilst the old law from an accusation of concealment of birth could deduce a charge of murder, the modern law can only deduce the charge of concealment of

birth from an accusation of murder. In Scotland the law, after passing through variations similar to that of England, may now, with certain technical differences, be said to be the same as in the sister country. The Act 1690, c. 21, was in all respects identical with the 21 Jac. I., c. 27. The existing statute is 49 Geo. III., c. 14, by which concealment of pregnancy is punishable with imprisonment for a period not exceeding two years, whilst the putting to death of an infant child still remains murder at common law. A large proportion of the murders committed in England falls under this head; and much the same must be said of other modern nations. A recent traveller relates that in the penitentiary for women at Prague, of the 400 women confined there, 180, or thirty-two and a half per cent., had been convicted of child murder. It is one of the most difficult questions of medical jurisprudence, from the ease with which infant life may be destroyed, to establish the murder of a child lately born. An exhaustive consideration of this will be found in Dr. Wm. Hunter's celebrated essay 'On the Uncertainty of the Signs of Murder in the case of Bastard Children,' written in 1783, and published in the 'Medical Observations by a Society of Physicians in London.' The chief points for decision are—1st, whether the infant, the subject of inquiry, was born dead or alive; and 2nd, whether its death was the result of violence or of natural causes. If the result of the evidence be that the child was born alive, and that it was destroyed, the offence is murder. There are institutions in this country, as well as many other European countries, which have been founded with the view of restraining infanticide.

INFANTRY is a name given to the soldiers who serve on foot. Among the ancient nations of Europe the foot soldiers constituted the chief strength of the armies. In the best days of the Grecian and Roman states battles were mainly won by the force and discipline of the phalanges and legions, and the number of the infantry in the field far exceeded that of the cavalry. The ancient Franks fought on foot; and, in this country, the greater part of the Anglo-Saxon forces consisted of infantry. But soon after the time of Charlemagne the institutions of chivalry began to be generally adopted in the kingdoms of Europe; and, by degrees, the cavalry, which was composed of persons possessing rank and property, and completely armed, acquired the reputation of being the principal force in war; the foot soldiers, ill-armed and disciplined, were held in comparatively small estimation.

The infantry of this country, for some time after the Conquest, consisted of the yeomanry, vassals, and dependents of the feudal tenants; and occasionally foot soldiers were engaged by the kings, under indentures, to serve in the wars. Louis XI. of France formed a standing army of 10,000 French infantry, to which were joined 6000 Swiss; and subsequently Charles VIII. added a large body of Lansquenets, or German infantry. The reputation of the native troops in France was then at a low ebb, but the Swiss soldiers were inured to discipline; they were protected by defensive armour and formed into deep battalions, in which state they were able to render the shock of cavalry entirely unavailing.

The Spanish soldiery, probably from being almost constantly engaged in warfare with the Moors, had

early acquired considerable reputation; and, subsequently, the great share which it had in the wars carried on both in Italy and Flanders, its steady discipline, and the success which resulted from the association of musketeers with pikemen in the battalions, caused the infantry of Spain to be considered, during many years, as the best in Europe. To this state of excellence it was mainly brought by the labour and genius of Gonzalo de Cordova, styled the 'Great Captain.' England, France, and Germany soon adopted the improvements introduced by the Spaniards; and it may be added that the practice of keeping up standing armies composed of men trained in the art of war under a rigid system of discipline, together with the universal adoption of the musket, has now brought all the infantry of Europe to nearly the same degree of perfection. In the United Kingdom great attention has, of late years, been paid to the improvement of this arm of the service; and by the establishment of schools of musketry at Hythe, Fleetwood, and elsewhere, the British infantry have been rendered superior marksmen. Their social condition has also been ameliorated; their barracks and clothing improved; and educational advantages are now placed within the reach of every private. The superiority of this class of troops consists in their being able to act in positions where cavalry cannot move, and it is obvious that the latter must at all times have been nearly useless in the attack and defence of towns. Even when cavalry was held in highest estimation, it was sometimes found convenient for the knights to dismount and act as infantry; and as war has become a science, the principal strength of armies is found to lie in their infantry. For the number of infantry in the British army, see GREAT BRITAIN.

INFECTION is the contamination of the atmosphere or other inert substances by the deleterious or offensive qualities of malaria, the matter of contagion, effluvia from putrid animal or vegetable substances, &c. Some of these are at once recognized by the smell, or by chemical analysis, but the presence of others is known only by the diseases which they produce. The same means, however, may be applied for preventing the injurious effects of both classes.

The most important and valuable method of disinfection is ventilation; and, whatever others may be added to it, this should never be neglected. The reputation of chlorine, acids, lime, charcoal, &c., as disinfectants, depends on their property of decomposing the offensive gases which are so often mixed in the atmosphere with the matter of infection, but it is questionable whether they have any influence on the infectious particles themselves. However, as the emanations from putrid substances render the body peculiarly liable to the reception of infection, some of these means should be employed where any offensive smell is present. The best of these is chlorine, which may be applied in the form of chloride of lime, which should be poured over anything from which odour is emitted: it should be sprinkled about the floor and on the walls; or shallow vessels containing it should be exposed to evaporate in the air: or pure chlorine should be disengaged in the form of gas from the materials from which it is manufactured. Mr. Herapath, the

distinguished chemist, has recommended the following simple formula for the preparation of chlorine. Take a mixture of three parts of common salt and one part of black oxide of manganese, finely powdered and well mixed. This can be carried in a bottle, and when a person desires to render himself non-infectious, he will put a little into a plate or saucer, and pour upon it from ten to twenty drops of oil of vitriol, when chlorine gas will be instantly liberated. Let him pass the plate two or three times round him, and he will be rendered innocuous.

INFETMENT, in the law of Scotland, from the same origin as the English term feoffment, expresses the ceremony by which a person succeeding to another by descent, settlement, or conveyance, is invested in any heritable or real property. The cumbrous ceremony of infetment was rendered no longer necessary by the 8 & 9 Vict., c. 35, passed 21st of July, 1845, and called 'An Act to simplify the form and diminish the expense of obtaining infetment in heritable property in Scotland.'

INFEROBANCHIATA, the third order of *Gastropods* in the system of Cuvier, who describes them as having nearly the form and organization of *Doris* and *Tritonia*, but remarks that their branchiæ, instead of being placed on the back, are arranged in the form of two long suites of leaflets on the two sides of the body under the advanced border of the mantle. He records two genera, *Phyllidia* and *Diphyllidia*.

INFINITE, INFINITY, INFINITESIMAL CALCULUS. The word infinite means literally 'without bounds,' and when applied in an absolute sense to magnitude means that its quantity is utterly unlimited, so that there is no conceivable and determinable magnitude but what is less than the infinite magnitude.

The notion of infinity is therefore at first purely negative, but it does not long remain so: for we are forced upon what we take the liberty of calling a definite notion of infinity by our consideration of time, space, and number. We cannot, if we would, annihilate our conception of space, or confine it within certain limits; nor can we suppose duration to have an end. Even if we imagine our own annihilation, we cannot rid ourselves of the idea of something else existing, with the permanent conception of unbounded space and time. If we try to conceive all sentient existence at an end, we know from reasoning that we ought to suppose also the annihilation of space and time: but the constitution of our minds will not permit it, and as long as we exist to think, even about our own non-existence, the reality of space and time will prevent our conceiving their destruction.

The other extreme in the scale of quantity is the perfect absence of all magnitude, expressed in the word 'nothing,' or the technical term 'zero.' It is necessary to treat the two together in mathematical reasoning, since all difficulties which belong to the one term belong equally to the other. We have also to consider the words 'infinitely small' as well as 'infinitely great.'

There are three distinct methods of proceeding in regard to the employment of these terms in mathematical reasoning. Firstly, we have those who would use the words 'infinite' or 'nothing' in their

absolute sense, relying upon the reality of the conception which they have of the things signified by them. Secondly, there are others who would entirely banish the use of the words, because in their absolute sense they do not represent assignable magnitudes. Thirdly, others admit the use of the words, guarding them by definitions which point out the processes in the expression of the results of which they may be employed.

To the first it is answered that the absolute use of ∞ and 0 (the mathematical symbols of infinite magnitude and absence of all magnitude) in the same manner as symbols of definite quantity, is extremely liable to lead to error; which was never avoided by the advocates of this system, except by abandoning their theory, and applying in practice the maxims alluded to under the third of the preceding heads.

To the second of the three sects above mentioned it may readily be conceded that they have a right to refuse any branch of mathematical reasoning, so far as themselves only are concerned. But we deny that the code of mathematical controversy contains any such axiom as that 'mathematics is the science of assignable magnitudes only,' by which to claim the submission of an opponent. The general rule is, that mathematical demonstration exists wherever there is logical deduction from universally obvious maxims with respect to magnitude. Nor does the word 'universally' here mean that such maxims must have been obvious to every individual of the human race. If so, there would be no such thing as mathematical demonstration, for there have been found instances in which persons have denied that the sum of all the parts makes up the whole.

We proceed to enunciate the method followed by the third of the sects mentioned. If we look at the manner in which we derive the notion of infinity, we shall not find any one who imagines that he absolutely grasps infinite space, time, or number, by one single and independent conception of his mind. To space, space may be added; to this again space may be added; and so on without limit, until the space thus accumulated is greater than any definite space which was named at the outset of the process. From thence comes the notion of infinite: we cannot imagine the greatest possible space, because any space, however great, being distinctly conceived, we can as distinctly conceive a greater. Consequently the phrase 'space is infinite,' whatever more it may imply, certainly may be allowed to stand for an abbreviation of the preceding two sentences. And in like manner, if we see a conclusion which we can nearly attain by the use of a large magnitude, more nearly by the use of a larger, and so on without limit, that is to say, as nearly as you please, if we may use a magnitude as large as we please, but which is never absolutely attained by any magnitude however great—then such conclusion may be said, for abbreviation, to be absolutely true when the magnitude is infinite. It may appear to some as if the conclusion, under the preceding circumstances, is really true when the magnitude is infinite: this may or may not be the case, but the mathematical use of the word infinite does not require the question to be raised. The convention under which that term is introduced demands that the preceding con-

ditions shall be fulfilled, and excludes the word whenever they are not fulfilled: those who think that the fulfilment of the conditions makes that which we call a convention a necessary consequence, meet on common ground with those who would reject the absolute notion of infinity. The former are allowed their own words, and their own result, together with their own method of arriving at it; the latter are not required to use the word infinite, except as an abbreviation; to the mere collocation of the letters which compose that word they can hardly object, and the conditions of its introduction are precise and intelligible.

Our explanation of the term infinite will readily show the meaning of the following assertion: Two infinitely great quantities may have a finite ratio, as follows:—When A and B are great, their ratio may be nearly, say, that of 10 to 7; when they are still greater, they may be still more nearly in that ratio, and so on; and their increase may be so regulated that the greater they become the more nearly is their ratio that of 10 to 7; or as nearly as you please, if they may be as great as we please. Similarly:—Two nothings may have a finite ratio. This means that A and B, both diminishing together, may diminish in such a way that when both are small their ratio may be nearly, say, that of 5 to 3; when they are still smaller, they may be still more nearly in that ratio, and so on: and their diminution may be so regulated that the smaller they become the more nearly is their ratio that of 5 to 3; or as nearly as you please, if they may be as small as we please.

But the idea of two nothings which have a finite ratio, however strictly defined in accordance with the preceding conditions, shocks even many of those who can grasp the method of using the word 'infinity.' The absolute nothing of subtraction has possession of the field, and it is not worth while to contest it for the use of a word. The term 'infinitely small' therefore supplies the place of 'nothing' whenever the latter is introduced under the conditions correlative to the conditions under which the use of infinitely great is allowed.

INFLAMMATION (from *inflammo*, 'to burn'). When any part of the body is preternaturally hot, red, swollen, and painful, such a part is said to be inflamed, or in a state of inflammation; and when these symptoms prevail to a certain extent, or affect very sensible parts, that general constitutional disturbance called fever is excited.

Inflammation is said to terminate in three ways—by resolution, suppuration, and mortification. By the first, which is the most frequent mode of termination, is meant a gradual subsidence of the swelling, a diminution of the heat, pain, and redness, and an abatement of the fever; the parts return to their natural size and colour, and no pus or matter is formed. Suppuration is said to have taken place when the inflammation goes on to the formation of pus; the swelling then becomes more prominent, of a shining red colour, and soft in the centre; if now no artificial opening be made, the matter obtains exit through one or more orifices produced by the absorption of the walls of the cavity in which it is contained, and the abscess, in popular language, is said to have burst. Mortification is the least frequent but most severe mode in which inflammation

can terminate, and usually is productive of great constitutional disturbance; when it is the result of a high degree of inflammation, the attendant pain is exceedingly severe, the bright red colour of the part becomes livid, and vesicles form on its surface; complete death of the part then takes place, and the pain abates.

The treatment of inflammation consists in the removal of all exciting causes, the abstraction of blood generally and locally, the administration of such medicines as act either by lowering the circulation generally or increasing particular secretions, and in the employment of local emollient or sedative applications.

INFLEXION (Lat. *inflexio*, 'a bending'), in grammar, is that process by which declinable words are modified in languages where the pronominal and predicative roots are capable of combination into one word. This chiefly takes place in languages of Semitic and Aryan origin.

INFLEXION, in optics, corresponds to diffraction; that is, the property of light to turn from its direct course when it passes near the edge of an opaque body.

INFLEXION, POINT OF, in Geometry, the point of contact of a stationary tangent; namely, the point at which the curve passes from one to the other side of its tangent, and towards which it always turns its convexity. It is sometimes called a point of contrary flexure.

INFLORESCENCE, in plants, is the manner in which their flowers are arranged.

Inflorescence may be considered as regular or centripetal, and irregular or centrifugal: in the former all the parts are formed successively without interruption; in the latter the parts are subject to various derangements in the progress of their formation. As examples of centrifugal inflorescence we may take the Elder, Laurustinus, &c.

The centripetal inflorescence, in its simplest state, is merely a branch bearing flowers instead of leaf-buds, as in the Hyacinth and the Ornithogalum: if the flowers are sessile, it is then called a *spike*; if stalked, a *raceme*. If the branch of the spike or its axis is so much contracted as to become a broad disc, as in the Dandelion, or Daisy, or common Artichoke, the inflorescence is called a *head* or *capitulum*; if the same thing happens to a raceme, the *umbel* of Astrantia, Fennel, Parsley, &c., is the result. Let the flower-stalks of the raceme be branched or racemose, and the *panicle* is produced. To these primary forms of inflorescence all others are referable, as simple and generally unimportant varieties. See Plates 'Inflorescence' for examples of the modes of flowering of the plants belonging to the different natural orders.

INFLUENZA (i.e., owing to the influence of the stars), is the name given by the Italians to an epidemic catarrh, which has spread more extensively than any other epidemic; and this universality of its attacks, together with the greater severity of its symptoms, principally distinguishes it from common catarrh. It attacks all ages and conditions of life; but it seldom proves fatal except to the aged, or to those previously suffering from or having a tendency to pulmonary disease. Notwithstanding the great frequency of this epidemic, it is remark-

able how little variety there has been in its symptoms, and the records of cases which occurred in 1510 nearly resemble those which have been observed during its latest visitations. Another epidemic occurred in 1557, and spread not only over Europe, but also over the whole of the northern hemisphere. Beginning in Asia, it extended westward over the European continent, and reached to America, where it terminated. Numerous outbreaks have since occurred at widely different intervals. Its progress is not checked by oceans or rivers, and it attacks the sailor on the sea, as well as the dwellers on the land. It has frequently visited London with great severity. In September, 1729, it carried off 1000 persons weekly, and in 1847 the mortality arising from it was nearly as terrible. Its causes are still obscure, though there can be no doubt that its increase and diminution are closely connected with atmospheric changes. Dr. Cullen regarded it as contagious. Dr. Prout suggests that it originates in the existence in the atmosphere of some noxious and irritant vapour, though in very minute quantity. It may probably be of volcanic origin, and contains, perhaps, sulphuretted hydrogen. It always travels from east to west. The following are the symptoms which most generally characterize it:—The person is seized with slight chills; weight and pain, sometimes severe, are felt over the eyebrows; there is increase of the lachrymal and nasal secretions, with loss of appetite, prostration of strength, a weak, frequent pulse, dyspnoea, hoarseness, sore throat, and cough. The duration of the disease varies from one or two days to a fortnight, but great debility often remains behind for many weeks, and in some epidemics relapses have been frequent. In the aged it is very apt to prove fatal.

These epidemic visitations have taken place most frequently in the spring and autumn.

Mild aperients administered with caution, the exhibition of antimonial and saline medicines, and a cool temperature, constitute the means which experience has found to be most efficacious in the treatment of this disease.

IN FORMA PAUPERIS. [**FORMA PAUPERIS.**]

INFORMATION (Criminal), a complaint exhibited before the Court of King's Bench against a person for some misdemeanour. It differs from an indictment [**INDICTMENT**] principally in this, that an indictment is an accusation found by the oath of a grand jury, whereas an information is simply the allegation of the person who exhibits it. Informations are of two sorts: those which are partly at the suit of the king, and partly at that of a subject; and, secondly, such as are in the name of the king only. Informations which are partly at the suit of the king and partly at that of a subject, are generally exhibited upon penal statutes, which impose a penalty on the offender if he is convicted, one part of which is for the king and the other part for the informer.

Informations exhibited in the name of the king alone are either filed ex officio by the king's attorney-general at his own discretion, when they are called ex officio informations; or they are exhibited in the name of the king by some private person or informer, and are filed by the master of the crown office. Ex officio informations are filed in the case of great misdemeanours which disturb the king's government,

or interfere with the discharge of his kingly office. Those filed by the master of the crown office relate to riots, batteries, libels, which disturb the public peace, but do not directly tend to disturb the king's government. When any information is filed, it must be tried in the usual way by a petit jury in the county in which the offence was committed. An information on behalf of the Crown filed in the Court of Exchequer by the attorney-general, is a method of suit for recovering money or other chattels, or for obtaining damages for any personal wrong. The most usual informations are those of *intrusion* and *debt*.

When it is necessary for the Court of Chancery to interfere with the regulation or management of any charity, the attorney-general as informant, on the relation of some person (who is called the relator), files an information in the Court of Chancery for the purpose of bringing the case before the court. This is simply called an information.

INFORMER, in English law, is a person who lays an information or prosecutes any person for some offence against the law, or a penal statute. Such a person is generally called a common informer, because he is supposed to make a business of laying informations for the purpose of obtaining his share of the penalty. Persons are induced to take the trouble of discovering offences, for which a pecuniary penalty is inflicted on the offender, by the promise of the reward; and if the penalty is imposed for the public interest, he who makes the offender known does the public a service. Of late years, since the establishment of the police force, the common informer's vocation has almost fallen into desuetude.

In Scotland an informer is the party who sets the Lord-Advocate in motion in criminal prosecutions, and he is liable to action-at-law in case of a malicious prosecution.

INFRA LAPSA'RIANS (*infra*, 'below,' *lapsus*, 'a fall'), a sect of predestinarians, who held that a certain number of men had been born to be damned, without the means of saving themselves if they would.

INFUSIONS are solutions of some of the principles of vegetables, generally in water, but occasionally in other vehicles. When water is employed, it may either be hot or cold. It is customary to use warm water, but in many instances cold is preferable. Sometimes alcohol is added, after straining, to assist in keeping the infusion, or to increase its powers. Hard water should, if possible, be avoided in the preparation of infusions.

INFUSORIA. (Lat. *infundo*, 'I pour in.') a title applied by Otto Muller to the numerous minute animals found in water (and especially in water in which vegetable matters are contained), and to which the term *Animalcules* is commonly given. From the invention of the microscope by Hooke may be dated the discovery of a new world of aquatic organic beings of such inconceivable minuteness, that, in the space of one cubic inch of water, more than 800,000 millions may revel in the enjoyment of their existence. There is not a drop of the ocean, of lakes, ponds, or rivers that does not teem with life, each drop perhaps containing nearly as many tenants as there are human beings on the surface of the globe. To Linnæus and the naturalists

of his time the structure of these minute animals was not well understood, and they were placed at the end of the class *Vermes*, in a genus denominated *Chaos*; but from the recent improvements of the microscope and the diligent investigations of zoologists, among whom Hemprich, Ehrenberg, Rymer Jones, and Gosse claim a foremost place, our knowledge of these atoms of life is greatly improved, and little remains for elucidation.

Cuvier divided the Infusoria into *Rotifera* and *Homogenia*; but the former are now placed by Professor Owen among the *Radiata*. For the latter (*Homogenia*) Ehrenberg substituted the appellation *Polygastrica*.

The *Rotifera* derive their name from the appearance of wheels turning round and round near the mouth, or at the upper part of the body, with great velocity. This appearance is deceptive, and is found to arise from circlets consisting of minute cilia, which in rapid succession bend and unbend, producing the effect sometimes of waves chasing each other in a ring, at other times of wheels in rapid whirl. These cilia are sometimes quiescent, sometimes only partially agitated. They propel the microscopic beings through the water, and moreover serve for the acquisition of food. Fixing itself by means of caudal forceps to any object, the animal throws its cilia into violent action, producing a whirlpool in the contiguous water, whereby minute particles of animal or vegetable matter are drawn to the mouth. Some of the *Rotifera* (*Nuda*) are naked, others (*Loricata*) are covered with a delicate transparent horny or calcareous tunic, through which the internal viscera may be seen. The *Rotifera* are oviparous, possess a distinct digestive apparatus, and are very active and alert.

The *Polygastrica*, or 'many-stomached' animalcules, abound in the sea and fresh waters. They are divisible into two groups; one distinguished by the soft or shell-less condition of the body; the other by the body being more or less protected by an extremely fine and transparent shell, varying greatly in form in different species. Some of the *Polygastrica* present wonderful changes of form, and seem as if they had no definite or settled configuration. They are evidently endowed with instinct; they know how to pursue their food, what to take, what to reject, and how to avoid danger: the larger make the smaller their prey. The minutest of these animalcules which the finest microscopes have brought within our vision are termed *Monads*. With respect to organs of locomotion, some make for themselves at will arms or paddles by shooting forth portions of their body; others are furnished with vibratile cilia; but in some no special organs of locomotion can be discerned. According to Ehrenberg the digestive apparatus consists of a mouth leading to a number of internal sacculi, or stomachs, variously arranged in different species.

Reproduction is by buds, by spontaneous division, and by eggs.

This arrangement was hailed by working naturalists, at the time it was published, as one which had carried light into a department of natural science then little understood. But it is now (1866) wholly superseded. The *Infusoria* are ranked as a class, whose limits are pretty well defined, under the sub-

kingdom PROTOZOA, the lowest group of the Animal Kingdom, the Cœlenterata being the second lowest. The following is a correct definition of the class;— 'Infusoria are animals belonging to the department Protozoa, provided with a mouth and rudimentary digestive apparatus; their bodies usually consisting of three distinct layers, the outer of which is, in most cases, furnished with a variable number of cilia.' They are microscopic. It is customary in many works to describe fossil Infusoria, but there are no true fossil forms of this group, the organisms so called being *Foraminifera*, *Diatomacea*, &c. The reader will find a full description of the true place of *Infusoria* in the zoologic scale under PROTOZOA, which see. The Plates 'Infusoria' contain the figures and names of many forms which have long been ranked by naturalists under this class.— (See Rymer Jones, *Structure of Animal Kingdom*; Gosse, *The Aquarium*; Darwin, *Origin of Species*; and Lewes, *Sea-side Studies*.)

INGA, (the South American name for one of the species), a genus of plants of the natural family of *Leguminosæ*, which, though it has been separated from *Mimosa*, still contains upwards of one hundred species. These are found in the tropical parts of America. A few of the useful species have been further separated into the genus *Parkia*; but many still remain which are important in the countries where they are indigenous, either for astringent properties, like many *Mimosas* and *Acacias*, or for the edible nature of the fecula or pulp which surrounds their seeds.

INGENHOUSZ, JOHAN, a distinguished natural philosopher, was born in 1730 at Breda, and for some years practised medicine in that city. He afterwards came to London, where his discoveries in chemistry and electricity led to his being elected a fellow of the Royal Society in 1769. He practised as a physician in London, and his reputation was such that he was sent for to Vienna by the Empress Maria Theresa, in 1772. After an absence of several years he returned to England, and continued to prosecute experiments in electricity, chemistry, &c. An account of an electrophorus, which he had invented, appears in the 'Philosophical Transactions' for 1778. This probably led to the invention of the plate electrical machine, which is generally ascribed to Ingenhousz. About the same time he made the discovery that growing plants exposed to the light discharge oxygen gas from their leaves into the atmosphere; and his researches relating to this subject were published in London in 1779, under the title of 'Experiments upon Vegetables, discovering the power of purifying the Air in the Sunshine, and of injuring it in the Shade,' &c. Died September 7, 1779.

INGFANGTHEF, among the Anglo-Saxons, a privilege granted to lords of manors, to try and bring to judgment any thief taken within their boundaries. (Bracton.)

INGLIS, SIR ROBERT, formerly chairman of the East India Company, and many years M.P. for the University of Oxford, was born in London in 1786. He was educated at Winchester College, under the late venerable Bishop Huntingford, and at Christ Church, Oxford, under Dr. Cyril Jackson. In 1818 he was called to the bar, and subsequently

elected Recorder of Devizes. In 1812 he was appointed one of the Commissioners for the settlement of the affairs in the Carnatic, which office he held for many years. He first entered Parliament in 1824, as member for Dundalk, and in 1826 was elected for Ripon; but on the change of policy on the part of Sir Robert Peel, with regard to the Catholic question, Sir Robert Inglis was selected by the Protestant party as his substitute, and returned for the University of Oxford. He was not only an active member of the House of Commons, many of his speeches having been published, but he took an active part in numerous religious and educational societies connected with the Established Church; and was president, vice-president, or trustee, of most of the learned or scientific bodies of the great metropolis. He was the second baronet of the name, but with him the title became extinct. He died in 1855.

INGOLSTADT. [REGEN.]

INGOUVILLE. [HAVRE.]

INGRAM, REV. DR. JAMES, President of Trinity College, Oxford, and Rector of Garsington, was born at East Codford in 1774. After graduating at Oxford, in 1800, as M.A., he was, in 1803, unanimously elected Anglo-Saxon Professor, on the foundation of Dr. Rawlinson. In 1807 he published an 'Inaugural Lecture on the Utility of Anglo-Saxon Literature;' and in 1809 he superintended a new edition of 'Quintilian de Institutione Oratoria.' In 1824 he was elected President of his college, to which office the rectory of Garsington is annexed. In 1823 he brought out a new edition of the 'Saxon Chronicle,' with an English translation. His 'Memorials of Oxford,' with plates prepared by Mr. Parker, is a work held in much estimation. He died in 1850.

INGULPHUS, the author, or supposed author, of a work entitled 'Historia Monasterii Croylandensis' (the History of the Monastery of Croyland, or Crowland, in Lincolnshire), was born in London about the year 1030, and was educated, first at Westminster, and afterwards at Oxford. He was introduced to Duke William of Normandy when that prince visited the court of Edward the Confessor in 1051, and made himself so acceptable as to be appointed his chief minister. After some years he relinquished this situation to accompany Sigfrid, duke of Mentz, on a pilgrimage to the Holy Land. On his return, he became a monk in the abbey of Fontenelle in Normandy. Here he remained till 1076, when he came over to England on the invitation of William the Conqueror, and was appointed abbot of Croyland. Here he resided till his death, December 17, 1109. The history of Croyland, the only work claiming to be his now extant, was first printed entire, along with the continuation by Peter of Blois, in the 'Rerum Anglicarum Scriptorum Veterum,' tomus primus, folio, Oxon., 1684. A very formidable attack was made upon its claims to be regarded as anything better than 'an historical novel,' a mere monkish invention or forgery of a later age, by Sir Francis Palgrave, in an article in the *Quarterly Review* for June, 1826 (No. 67).

INHIBITION, in the law of Scotland, is a proceeding by which a creditor may prevent his debtor from alienating property either to favoured creditors

or other persons until the debt of the creditor is paid: nominally it affects all property, but it is only in the case of real property that, from its being put on the register, it is efficacious.

INIS (from Latin *Insula*), an Irish word, signifying island, used as a prefix (*Inisfallen*), and apparently corresponding with the Scottish *inch*.

INJECTIONS. [CLYSTERS.]

INJUNCTION. An injunction is a writ which issues by the order and under the seal of a court of equity, and is of two kinds, remedial and judicial.

The remedial writ is used for the following purposes among many others: to restrain parties from proceeding in other courts, from negotiating notes or bills of exchange, to prevent the sailing of a ship, the alienation of a specific chattel, to prevent waste by felling timber or pulling down buildings, the infringement of patents or copyright, to repress nuisances, and to put an end to vexatious litigation. The writ of injunction is useful in stopping or preventing wrongs for which the ordinary legal remedy is too slow.

The judicial writ of injunction is virtually abolished by the Statute 11 Geo. IV. & 1 Will. IV., c. 36, s. 11.

INK (Dutch *inkt*; French *encre*, from the Greek *ἐγκαιστος*) consists of several varieties, the most important being writing and printing ink.

Writing Ink.—The writing ink of the ancients was essentially different from that which is now employed. Its basis was finely divided charcoal, mixed with some mucilaginous or adhesive fluid: it was much less destructible than modern writing ink, and somewhat more resembled printers' ink. Writing ink is now a chemical compound, and not a mere mechanical mixture. Its basis is proto-gallate and proto-tannate of iron, which by oxidizement become per-gallate and per-tannate; and it is owing to the oxygen of the air effecting this change gradually that recent writing is of a comparatively light colour, and that it subsequently becomes of a deeper black.

Many processes have been given for preparing writing ink. The common ingredients are galls and sulphate of iron; in fact, while printers' ink may be considered as a black paint, writing ink may be regarded as a black dye. We shall not copy the different modes which have been adopted. The following, which is recommended by Professor Brande, gives, he says, an excellent ink, and it possesses the merit of greater simplicity than most others:—Aleppo galls, bruised, six ounces; sulphate of iron, four ounces; gum arabic, four ounces; water, six pints. Boil the galls in the water, then add the other ingredients, and keep the whole in a well-stopped bottle, occasionally shaking it. In two months strain and pour off the ink into glass bottles, to be well corked. To prevent mould, add one grain of corrosive sublimate, or three drops of creosote, to each pint of ink.

Stephens' Ink—a blue fluid, which shortly after use becomes an intense black—mainly consists of gallo-tannate of iron, dissolved in sulphate of indigo. Runge's black writing fluid is prepared from chromate of potash and a solution of logwood, and is not affected by exposure to water or acids, and does not corrode on steel pens like ordinary ink.

Red Ink is of two kinds—one made from Brazil-wood, and the other from cochineal or carmine. The latter is prepared as follows:—'Add to a quantity of common carbonate of potash, soda, or ammonia, twice its weight of crude argol in powder. When the effervescence has ceased, decant or filter the solution from the insoluble matter. To this fluid add by measure half its quantity of oxalate of alumina. The mixture thus prepared is next coloured, when cold, with bruised or powdered cochineal, and after standing for forty-eight hours, is strained, when it is fit for use.' (Musprratt's *Chemistry*.)

Blue Ink is made sometimes from indigo, and sometimes from Prussian blue as a basis. Stephens' method is to dissolve the latter in an aqueous solution of oxalic acid.

Other fancy-coloured inks, as purple, green, and yellow, have been made by various chemists, but have not come into general use.

Printers' Ink is of two kinds: for letter-press printing and for copper-plate printing. Printers' ink is prepared by boiling linseed or nut oil in an iron pot; and if it does not take fire of itself it is kindled, and suffered to burn for about half an hour; the flame is then extinguished by closely covering the vessel, and the oil is by this operation found to have acquired the necessary drying quality, after being again boiled. It is then mixed with a proper quantity of lamp-black, when black ink is required; carmine, lake, vermilion, for red ink; indigo or Prussian blue for blue ink; lemon and orange chrome, or gamboge, for yellow ink; and the whole is drawn off, and finally ground into a smooth uniform paste. Copper-plate printers' ink is made with oil which is less boiled, and the charcoal used is stated to be Frankfort black, made from vine twigs.

Indian Ink.—The cakes of this ink are made of lamp-black and size, or animal glue, with the addition of perfumes or other substances not essential to its quality as an ink. It is used in China with a brush, both for writing and for painting upon paper of Chinese manufacture. It is used in Europe for designs in black and white, in which it possesses the advantage of affording various depths of shade, according to the degree of dilution with water.

Marking ink is employed for marking linen; it is a solution of nitrate of silver, (one drachm in half an ounce of water, previously thickened with a little sap green), written with a pen upon the fabric to be marked, after it has been moistened with an alkaline solution, as potash or soda. By this process oxide of silver is precipitated upon and combines with the cloth so as to be scarcely removable by any re-agent which does not also destroy its texture.

Sympathetic Inks are such as are invisible until heat is applied, and then, by the chemical change induced, the writing becomes visible. The most remarkable of these is that prepared from cobalt, called Hellot's Sympathetic Ink, which is a chloride of the metal. When the written paper is held to the fire so as to evaporate the water, the letters become green. The inks used in Lithography are described under **LITHOGRAPHY**.

The value of the different kinds of ink imported into the United Kingdom in 1864 was as follows:—writing ink, 268*l*.; printing ink, 2184*l*.; and Indian

ink, 593*l*. The total value of the three kinds exported in the same year was 980*l*.

INKERMANN, a ruined Russian village in the Crimea, near the eastern extremity of the harbour of Sebastopol, and 37 miles S.W. from Simpheropol. It is memorable as the scene of a great battle between the allied Anglo-French army and the Russians, on Sunday, November the 5th, 1854, in which the latter were repulsed with great loss. From the little generalship displayed on the occasion, and the brilliant valour with which our troops behaved, it has been termed 'the Soldiers' Battle.'

INLAND BONDING TOWNS are places approved under the provisions of 22 & 23 Vict., c. 36, for the warehousing of goods under bond for the security of duties of customs. By the first section of the said act, power is given to the lords of the treasury to appoint Manchester, Birmingham, Leeds, and Sheffield, or any of them, and such other towns as they may see fit, to be warehousing places. By the second section, the powers and authorities conferred by the Customs' Consolidation Act, 1853, upon the commissioners of the treasury, for the appointment of warehousing ports, and upon the commissioners of the customs for the approval of warehouses in such ports, shall extend to and be applicable to the said inland bonding towns, or to any other places in the United Kingdom having a sufficient consumption of articles paying customs duties to justify the expense of a customs establishment. The only towns as yet enjoying the privilege of the 'Customs' Inland Bonding Act, 1860,' are Bradford, Halifax, Leeds, and Manchester.

INLAND REVENUE. The inland revenue is that portion of the revenue of a country which is raised on articles produced or taxed within it, as distinguished from the customs, or the duties upon articles imported from abroad. The three great sources of the inland revenue of the United Kingdom are the excise and stamp duties, and the land, income, and assessed taxes.

The excise duties had their origin in the reign of Charles I., when a tax was laid upon beer, cider, and perry of home production. The Act by which these duties were authorized was passed by the Long Parliament in 1643. It was adopted and enforced by Oliver Cromwell; and in the reign of Charles II. they were granted as a part of the revenue of the Crown. For a long time duties of this class were viewed with great dislike by the people, on account of their inquisitorial interference with various industrial pursuits; and it certainly formed a very strong ground of objection against excise duties, that the security of the revenue they yielded was held to be incompatible with the perfect freedom of the manufacturer as to the processes which he might apply in his works. In every highly taxed country it would, however, seem to be hardly possible to avoid their adoption; much indeed may be said in their favour, as compared with other taxes, when they serve to extract money for national purposes from personal expenditure on luxuries, especially when, as in the case of alcoholic liquors, their excessive use becomes a vice.

In 1797 the number of articles subject to excise duties was 28, including such an indispensable necessary of life as salt. In 1833 the number had been

reduced to 15; in 1835 to 10; and in 1845 there were only 9. In the latter year the late Sir Robert Peel commenced a reform in the excise laws by repealing the duty on glass, and by substituting a license for auctioneers, instead of the excise duties on the sale. Bricks and soap were subsequently relieved from the impost; and in 1861, after a long struggle, that on paper was removed. In 1862 an increased brewer's license was substituted for the excise duty on hops; and the only articles now subject to this tax are spirits, malt, and chicory—a duty being imposed on the latter rather with the view of preventing its too extensive use in the adulteration of coffee than of adding very materially to the revenue.

It is therefore manifest that in this country the real objections made to excise duties have been almost entirely invalidated; for although complaints are sometimes made respecting the imposition of the malt duty in relation to the growth of barley, it cannot be said that a slight tax on beer and a heavy one on spirits at all interferes with important branches of trade, or sensibly diminishes the comfort and well-being of the population at large. There are still, it is true, certain duties to which the name of excise is applied, which can hardly be called duties on consumption, although they are accessory to it, such as the sums charged for licenses to carry on certain trades and professions.

The chief danger to guard against in the imposition of excise, as well as customs duties, is fixing the rate so high as to almost offer a premium on smuggling and illicit distillation, and thus defeat the very object sought to be attained—the realization of as large an amount of revenue as possible.

Prior to 1823 there were separate and independent Boards of Excise for England, Scotland, and Ireland, and the total number of commissioners was twenty-one. The business was then transferred to one board of seven commissioners in London, who, in addition to their other duties, held courts and decided summarily in cases of the infraction of the excise laws. In 1849 the Board of Excise was incorporated with that of the Stamps and Taxes, under the name of the Board of Inland Revenue: and breaches against their revenue laws must now be decided by the ordinary legal tribunals. The salaries of the persons employed in the Excise department, at the head office in London, range from 90*l*. to 550*l*. per annum. For the management of the country business of the department the whole of the United Kingdom is divided into collections, and these are subdivided into districts, rides, and divisions. There are about sixty collections in England and Wales, and at the head of each is a collector, who visits the principal towns in his circuit eight times a year, to receive the duties and transact other business connected with the department; besides which he is required to have an eye generally upon the discipline and efficiency of the service. The number of officers in a collection varies from forty to ninety. The next subdivision of a collection is the district, at the head of which is a supervisor. Next come the subdivisions of the districts into divisions, or foot-walks and rides. Where the traders are scattered, the officer is obliged to keep a horse, and his circuit is called a ride; but if a large number of traders reside in a smaller circuit, they are visited by the officer on foot, and then the subdivision is termed

a division, or foot-walk. Before going out each day, the officer leaves a memorandum at his home which states the places he intends to survey, and the order in which he will visit them; and the exact time at which he commences each must be entered in his journal. The supervisor re-surveys some of the officer's surveys, but which they will be the officer is of course ignorant; and if errors are discovered they must be entered in the supervisor's diary. These diaries are regularly transmitted to the chief office, and no officer is promoted unless the diaries show him to be efficient. The removal of officers from one part of the country to another was Mr. Pitt's suggestion, and is still acted upon to a certain extent, but, unless in case of promotion, is now generally optional with the officer. At the chief office in London there is a department of Surveying-General Examiners, who are despatched to any district without previous intimation, as a check upon the accuracy and integrity of the supervisors. Promotions take place in the excise department as vacancies occur, but only

when the officer has petitioned for advancement. This involves a rigid examination into his qualifications, which is termed 'taking out a character.' The number of excise officers at present employed in the United Kingdom is about 2300, and of late years their pay and prospects have been slightly improved. Second-class assistants (the lowest grade) now commence at 60*l.* per annum, and 2*s.* per day extra when employed; first-class assistants receive 95*l.* a year; ride officers, 110*l.*, with 20*l.* additional for keeping a horse; division officers, 130*l.* to 150*l.*; and supervisors, 210*l.* to 250*l.* per annum.

The principle on which revenue is derived from stamps and taxes is noticed in the articles STAMPS, TAX, and TAXATION.

In the following elaborate tables full particulars will be found of the various sources of national income, under the supervision of the Board of Inland Revenue, and the amount derived from each during the last seven years. Details as to the income tax will be found in the article INCOME TAX.

* Those who take alarm at the large consumption of intoxicating liquors must remember that, notwithstanding the increase of population, the quantity consumed is now very considerably less than it was some years ago—before the duties were raised. The year 1852 was the last before those alterations in the rates of duty commenced, which terminated in 1860 in a uniform rate of 10*s.* throughout the kingdom. The consumption in 1852 was nine-tenths of a gallon per head of population, but the present consumption is little more than six-tenths of a gallon per head, and yet there is an increase of nearly 4,000,000*l.* in the revenue. If we include the foreign and colonial spirits consumed the quantity was still almost a gallon and one-tenth per head in 1852, and not quite nine-tenths of a gallon in 1864. Of wine the consumption has risen in the same period from '23 of a gallon per head to '38, and of beer from '6 of a barrel to '7. These facts show the tendency towards the substitution of milder stimulants for ardent spirits. Comparing still the years 1852 and 1864, the consumption of beer in England will be found to have increased nearly 12 per cent.—viz., from '85 of a barrel per head to '95; in Scotland, 60 per cent.—viz., from '20 of a barrel to '32; in Ireland, 122 per cent.—viz., from '09 of a barrel to '20.

† From the amounts in this column a deduction must be made for drawbacks and other allowances (chiefly on malt and spirits), which in each of the two last years amounted to about 650,000*l.*

The following were the principal alterations in the rates of Duties, &c., in the above period:—

1860:—Licenses—England and Ireland—to keep Refreshment Houses, and to Retail Foreign Wine, at various rates, imposed from July 1, 1860. Spirits—United Kingdom—Duty increased to 10*s.* per gallon, from July 17, 1860. Chicory—United Kingdom—Duty of 3*s.* per cwt., imposed from August 28, 1860. Licenses—United Kingdom—To Dealers

in Sweets or made Wines, 5*l.* 5*s.*, imposed from August 28, 1860. The revival of the duty on Sugar used in brewing further deferred.

1861:—Paper duty repealed from September 30, 1861. Chicory duty increased on April 1, 1861, 2*s.* 6*d.* per cwt., and on June 12, 3*s.* per cwt.

1862:—Hop duty repealed from June 3, 1862. Chicory duty increased on April 1, 1862, from 8*s.* 6*d.* to 11*s.* per cwt. Brewers' Licenses increased

from October, 1862, and mode of rating altered. Victuallers' Occasional Licenses imposed, 5s., June 3, 1862.

1863:—Chicory duty increased from 11s. to 17. 1s. 9d. per cwt., from June 8, 1863. State Carriages used occasionally only—Daily Licenses granted at various rates, and the License and Duty on Stage Carriages to convey not more than eight persons, reduced from 3*l.* and 1*d.* per mile respectively to 10s. and ½*d.* per mile, from June 29, 1863. Victuallers' Occasional Licenses—Rates altered to 2s. 6*d.* per day, and 10s. for any number of days not less than four nor exceeding six after the first six days, from June 29, 1863.

1864:—Chicory duty increased from 17. 1s. 9d. to 17. 4s. 3*d.* per cwt., from April 1, 1864. Licenses to sell Tea, &c., duty reduced to 2s. 6*d.* where house is rated to the Relief of the Poor at less than 8*l.* Occasional Licenses to sell Wine, Beer, and Tobacco, not exceeding three days. Wine or Beer, 1s. per day. Tobacco, 4*d.* per day. Licenses to Hawkers, Dealers in Plate, Appraisers, House Agents, Pawnbrokers, Sellers of Playing Cards and of Patent Medicines, transferred from the Stamps to the Excise.

INLAYING is the art of inserting pieces of one substance in cavities cut in the surface of another, as a means of ornament. The substances may be various kinds of metal, or wood, pearl, ivory, tortoise-shell, &c.; and the product may either be regarded as a work of art, or as an ornamental article of furniture. Two kinds which had much celebrity in their day, but are perhaps less practised at present, are *buhl* and *reisner* work, so named from two cabinet-makers, Buhl, an Italian, and Reisner, a German, who settled in Paris in the reign of Louis XIV. Buhl mostly used a brass inlay on a tortoise-shell ground; Reisner, a dark wood inlay on a tulip-wood ground; but it is obvious that the varieties admit of almost interminable change. Where the substances are not too hard to be easily cut, the devices are produced by counterpart sawing; that is, two thin plates are laid one on another, and a very fine saw is worked through both of them, in lines marked out by a pencil device. If we suppose that two veneers or thin layers of wood, one black and one white, were thus treated, there might be two pieces of inlaying produced, the one a black inlay on a white ground, and the other a white inlay on a black ground, for one veneer would exactly fit the holes cut in the other. The saws for this work are mounted in bow or arched handles; they are very narrow and thin, and are worked in short quick movements. In buhl work the patterns generally consist of continuous lines; this does not require the actual separation into small pieces, and thereby marks one point of difference between inlaying and mosaics.

The ornamental stone-work called *pietra dura* bears more resemblance to inlaying than to mosaic, for the holes are not cut through the ground, but only to a certain depth, in slabs of black marble; and small bits of other coloured marble are inserted to this limited depth. The inlaying of knife and fork handles with studs of gold and silver is similarly effected by drilling holes to a certain depth, and inserting fragments of gold or silver wire. The inlaying of *papier-maché* with pieces of mother-of-pearl, or other iridescent substances, is not strictly

VOL. VII.

inlaying in the sense here employed; for the decorative substance, cut into the forms of leaves, flowers, or other devices, is laid on the *papier-maché*, and a general level produced by many thicknesses of varnish, in the way described under *PAPIER-MACHÉ*. See also *MOAIC*.

INN. An innkeeper is responsible for the safety of the goods of persons who use his house; but he may be released from his liability either by inattention on the part of the guest to such reasonable rules as the innkeeper may lay down for the protection of the property of his guests; by any act of negligence on the part of the guest himself; or by his making use of the house not *causâ hospitandi*, that is, not for the purpose of using it as an inn. Thus, if an innkeeper requires his guest to put his goods under lock and key, and the guest leaves them in a passage, whereby they are lost; or the goods are stolen by the guest's own servant; or the guest uses his room in the inn as a show-room, into which a number of people are allowed to have access, and not as a lodging-room, the responsibility of the innkeeper ceases. By the 26 and 27 Vict., c. 41, 'No innkeeper shall be liable for any loss or injury to a guest's property, not being a horse or other animal, or a carriage, to a greater amount than 30*l.*, except where such goods shall have been lost, injured, or stolen, through the wilful act, default, or neglect of the innkeeper, or any servant in his employ, or where the property has been deposited expressly for safe custody with such innkeeper.' The innkeeper may require the property to be sealed. If he refuses to take care of any article, or if he neglects to put up in a conspicuous place a copy of this Act of Parliament, the innkeeper cannot have the benefit of the Act. An 'inn' is defined to be 'any hotel, inn, tavern, public house, or other place of refreshment.'

An innkeeper is bound to open his house to all travellers, and provide them with such accommodation as he has, if the person applying is a traveller, able and willing to pay the customary hire, and is not drunk or disorderly, or tainted with infectious disease. In return for this compulsory hospitality, the innkeeper has a lien on the goods of his guest for payment of his bill, but he cannot detain the person himself.

The law relating to the licensing of inns is fully described in the article *ALHOUSE*.

The word 'Inn' was formerly used to designate the town-house of a great noble, as Lincoln's Inn. In France the word *Hôtel* was employed in the same sense.

INN, River. [AUSTRIA.]

INNISKIL/LINERS, or ENNISKILLINERS, a term in military language applied to the officers and soldiers of the 6th Dragoons and 27th Foot, on account of those two regiments having been originally raised at Inniskilling, a town of Ulster, where the inhabitants distinguished themselves in favour of William III. in his contests with James II.

INNOCENT I. and II. [POPE.]

INNOCENT III., Cardinal Lotharius, son of Trasimund, count of Segni, was unanimously elected in 1198, after the death of Celestine III. He ascended the papal throne at the age of thirty-seven. He had distinguished himself while at the universities of Paris and Bologna in the studies of philo-

c c

sophy, theology, and the canon law, and also by several written compositions, especially by his treatise 'De Miseria Conditionis Humanæ.' The object at which Innocent aimed was universal supremacy. External circumstances favoured his views. In Sicily he assumed the regency during the minority of Frederick II. At Rome, availing himself of the vacancy of the imperial throne, he bestowed the investiture on the prefect of Rome, whom he made to swear allegiance to himself; he drove away the imperial feudatories, took possession of those provinces in the name of the Roman see, and formed a league with Tuscany against the empire. In Germany he first deposed, and then excommunicated Otho, and secured the crown for his own ward Frederick of Sicily. Calo Johannes, prince of the Bulgarians, acknowledged his allegiance to the Roman see, and Leo, king of Armenia, received Innocent's legates, who bestowed upon him the investiture of his kingdom. Innocent excommunicated Sverecum, who had usurped the kingdom of Norway, and also Philip Augustus of France, because he had repudiated his wife Ingerburga of Denmark, and had married Agnes de Meranie. The King of Leon having married his cousin, the daughter of the king of Portugal, was likewise excommunicated, and as he would not submit, Innocent laid both kingdoms under an interdict.

He also laid the kingdom of England under an interdict in consequence of a dispute with King John, who eventually not only declared allegiance and paid him tribute, but surrendered the kingdoms of England and Ireland to the Pope and his heirs for ever. Against those who separated themselves from the body of the Roman Church, Innocent was stern and uncompromising. His persecution of the Albigenes is memorable for its malignity. He died in 1216. His pontificate must be considered as the period of the highest power of the Roman see. For various successors of the same name, see Article POPE.

INNS OF COURT AND OF CHANCERY. When the houses of law were first established seems very doubtful; but the fixing of the Court of Common Pleas at the palace at Westminster brought together a number of persons who (as Spelman says) addicted themselves wholly to the study of the laws of the land, and no longer considering it as a mere subordinate science, soon improved the law, and brought it to that condition which it attained under King Edward I. They purchased at various times certain houses between the city of London and the palace of Westminster, for the combined advantage of ready access to Westminster, and of obtaining provisions from London.

The inns of court, as they are now called, are Lincoln's Inn, the Inner Temple, the Middle Temple, and Gray's Inn.

The Inner Temple, as well as the Middle Temple, owes its name to the Knights Templars. After the dissolution of that order, it was granted to the Knights of St. John of Jerusalem by King Edward III., and was soon after, according to Dugdale, demised by them to 'divers professors of the common law that came from Thavie's Inn, in Holburne.' The church, which is common to both societies, was founded by the Templars, upon the model of that of

the Holy Sepulchre at Jerusalem, and was consecrated in 1185, and dedicated to the Virgin Mary. This church has been recently restored and beautified.

Lincoln's Inn is distinguished by its new *Hall and Library*, built by Mr. Hardwick in 1845, and justly regarded as one of the finest modern examples of the Tudor style. The chapel was built by Inigo Jones.

Besides these four inns of court there are nine inns of chancery, which are now only used as chambers, and are principally inhabited by solicitors and attorneys. Two belong to Lincoln's Inn, namely, Furnival's Inn and Thavie's Inn. Four belong to the Temple, Clifford's Inn, Clement's Inn, New Inn, and Lyon's Inn. Staple Inn and Barnard's Inn belong to Gray's Inn. There is also Serjeant's Inn.

Each inn of court is governed by its own benchers, who fill up the vacancies of their own body. The benchers of each inn exercise the power of calling to the bar the members of their own inn. [BARRISTER.] They also exercise the power of disbarring a barrister, that is, depriving him of his degree of barrister, if they see sufficient reason for such a proceeding.

INNSBRUCK, or *Innsbruck*, the capital of the Tyrol, is situated on the Inn, near the point where that river is joined by the Sill, in 47° 16' N. lat., 11° 23½' E. long., 245 miles W. by S. from Vienna, and has 14,500 inhabitants. The town is built in a most beautiful situation, in the middle of the valley of the Inn, which is hemmed in on both sides by mountains varying from 6000 to 9000 feet high. It takes its name of Innsbruck (Inn's Bridge) from the wooden bridge which spans the river, and on and near which the Tyrolese, under Hofer, during a fierce action, succeeded in repulsing the French after the war of independence. A handsome chain suspension bridge has also been recently erected. The town is in general well built; many of the houses are in the Italian style, the basement story consisting of arcades, which are occupied as shops. The street of Neustadt is the finest; here are the Landhaus or Tyrolese parliament house, the post-office, and, at its southern extremity, a triumphal arch erected by the Empress Maria Theresa. Among the public buildings, the most interesting is the Franciscan church, which contains the tomb (but not the remains) of Maximilian I., the most splendid monument of the kind in Europe, and the Silver Lady-chapel; the twenty-eight bronze statues that form part of its plan and represent some of the worthies of Europe, including the most distinguished personages of the house of Austria, were cast by Tyrolese artists; the bas-reliefs on the tomb, and in the Lady-chapel, which are masterpieces of art, were the work of Collin de Mecklin. On the left of the entrance to this church is the grave of Hofer, who so nobly defended his country against the French in 1809, until betrayed by one of his associates, and shot at Mantua by order of Napoleon. It is surmounted by a statue of the hero in Tyrolese white marble. The other remarkable buildings are—the Maria Theresa's palace, built in 1770, in whose court-yard stands an equestrian statue of Leopold V.; the university, in which is the Museum Ferdinandeum, rich in Tyrolese minerals, fossils, and works of art; the Capuchin church, containing the

penitential cell of Maximilian II.; the richly decorated church of St. James (Jacob's Kirche); the old palace of the counts of Tyrol; and the Fürstenburg, with its famous golden roof (goldene dach), a sort of oriel window, covered with a roof of gilt copper, which projects in front of the building. The public cemetery (Gottes-acker) contains some fine monuments. The Schiesstadt, where the Tyrolese practise rifle-shooting, is in a very pretty situation on the left bank of the Inn, on a slope of the Berg-Isel, and is well worth visiting. The market-place of Innsbruck presents a very interesting appearance, from the great variety of picturesque costumes worn by the inhabitants of the different valleys, who frequent it. The chief manufactures of the town are silks, gloves, calico, ribands, glass, sealing-wax, and wood and horn carved work; there is also an important transit trade. The neighbourhood abounds with beautiful scenery and charming promenades.

INOCULATION is the insertion of a morbid fluid formed in the body of one person into that of another. It has, however, been more particularly applied to the practice of producing small-pox by removing a small quantity of the fluid formed in the pustular eruption on the skin of one person, and inserting it beneath that of another. The disease is much mitigated by this process. The practice was introduced into this country by Lady Mary Wortley Montagu, about the year 1721, her son having thus received the disease during her residence in Constantinople. It had long been practised in Turkey and other Eastern countries. It was very slowly adopted in this country, and it was not until it had been practised on six criminals (whose liberty was promised to them if they recovered, as they fortunately did) that it was generally received. It was then almost universally had recourse to, till the introduction of vaccination, by which it has been superseded.

INOCULATION, in Horticulture, is only another name for the operation called budding. [BUDDING.] The season for performing the operation is, generally speaking, from the beginning of July to the middle of August, the particular time varying according to the season. The best criterion is the state of the buds and the degree of cohesion between the bark and alburnum of the stock. If the buds on the young shoots have become so far perfectly formed outside as to bear separation from the branch, and if the bark of the stock can be freely raised, and exhibits an abundance of cambium in a fluid state, the operation may be proceeded with. If, on the contrary, the bark adheres rigidly to the alburnum, or is *set*, as it is technically expressed, there is little chance of success. The operation of budding, or inoculation, is performed in various ways; but the best and most general is that called shield-budding or T-budding, from the resemblance of the two cuts made in the bark of the stock to the two principal bars of the Roman letter T.

IN PARTIBUS INFIDELIUM (Latin, 'in the regions of the unbelievers'). This is the title given to those Roman Catholic bishops who, residing in countries not under papal jurisdiction, have no diocese, nor any bishop's see. It has been the policy of the Romish Church to continue to appoint and consecrate bishops to Protestant and other countries where the Catholic religion has lost its sway, as a

continual protest against the power which had prevailed over its alleged right, and to signify its hope of restitution. Up to the year 1850 all the Roman Catholic bishops in Britain derived their titles from places abroad, it being illegal to assume territorial titles here. Since that date they have been allowed to take their titles from their actual sees; and the Ecclesiastical Titles Bill, which was expressly passed to prevent them, has remained a dead letter.

INQUEST, INQUISITION. [CORONER.]

INQUIRY, COURT OF. This is a court on some occasions directed by the Crown to be held, the object of which is to ascertain the propriety of resorting to ulterior proceedings against any party charged under the Mutiny Act.

INQUISITION, THE, (Lat. *inquisitio*, 'a seeking for'), of which the more correct title is the *Holy Office*, is the name of an ecclesiastical tribunal established in the thirteenth century, after the conquest of the Albigens by Popes Honorius III., Gregory IX., and Innocent IV., to try heretics, blasphemers, apostates, witches, wizards, and other persons charged with infractions of the canons of the Roman Catholic Church. The judges of this court were called 'Inquisitors,' whence the tribunal itself has been commonly called the 'Holy Inquisition.' From the time of Theodosius I., 382, heresy, or dissent from the creed of the national church, had been treated as an ecclesiastical offence in the Roman empire. In the eleventh and twelfth centuries persecutions were directed against the Waldenses, Albigenses, and other sects; but no special court distinct from the bishops existed till about the year 1233, when Pope Gregory IX. laid down the rules and defined the jurisdiction of the Inquisitors' courts, which he sent to various countries, under the name of Inquisitorial Missions. The Inquisition in Rome and other parts of Italy was intrusted to the Dominicans, and the principal characteristics of it as it existed from the thirteenth century to the latter part of the fifteenth were as follows:—The inquisitor visited the various provinces and towns, proclaiming to all persons the obligation he was under of informing against those whom he knew or suspected of being heretics, under pain of excommunication. At the same time he also made it known that all persons guilty of heresy who came of themselves before the inquisitor within a certain fixed period, and accused themselves and professed repentance, should receive absolution, and be only subject to a canonical penance. These penances were public, humiliating, and very severe. After the expiration of the period of grace, the inquisitor proceeded *ex officio* against those who were denounced, the name of the informer being kept secret. He examined witnesses privately in presence of a notary and two priests, and took down the evidence in writing. If there appeared sufficient evidence for proceeding against the accused, the inquisitor ordered his arrest by the municipal officers. He was then interrogated by the inquisitor, and his answers might be used afterwards as evidence against him. If the accused denied the charge of heresy, the inquisitor, together with the bishop of the diocese, or his delegate, if they thought proper, ordered him to be put to the torture in order to obtain his confession. The torture might be repeated three times. If in the end there were not sufficient grounds for the conviction

of the prisoner, he was declared to be 'suspected of heresy,' was obliged to make a public abjuration of all heresies, and was subject to certain penalties, according to the nature of the case. If he was convicted of heresy, but professed his repentance, he was condemned to prison for life—a penalty which, however, might be mitigated by the inquisitor. But if he was a *relapsed*—that is to say, had been tried before, and found guilty, or only strongly suspected—there was no mercy for him: he was '*relaxatus*,' given over to the lay magistrate, who, according to the civil and canon laws, was bound to put him to death upon the sentence of the inquisitor which declared him a heretic. The only favour shown to the relapsed heretic who confessed and abjured his guilt was, to be strangled before he was burnt. If the convicted heretic was not relapsed, but impenitent, a respite of the sentence was granted in order to effect his conversion; and if he at last abjured, his life was spared, and he was sentenced to perpetual imprisonment. If he persisted in his impenitence, he was publicly burned alive.

The Inquisition, thus constituted, was introduced in succession into Italy, Spain, Germany, and France. So long, moreover, as this constitution remained, it must be regarded as a strictly papal tribunal. Accordingly, over the French and German inquisition of the following century the popes exercised full authority, receiving appeals against the rigour of local tribunals, and censuring or even depriving the inquisitor for undue severity. In France the Inquisition was soon discontinued; and though an attempt was made under Henry II. to revive it against the Huguenots, the effort was unsuccessful. It fell into disuse in Germany at the Reformation. In England it was never received, all proceedings against heresy being carried on in the ordinary tribunals. In Poland it was established in 1327, but had only a brief existence. In Rome and the Papal States it has never ceased, though its history presents few cases of extreme rigour and cruelty.

It was in Spain and Portugal that the terrors of the Inquisition exercised the greatest sway. The Holy Office had existed in these countries from an early period, but was introduced in 1478 under a new and more appalling form, and became consolidated and permanent, and more absolute and independent than in any other country in Europe. A papal bull authorised Ferdinand and Isabella to appoint inquisitors, the execution of which they suspended for two years, in order to warn heretics of their error and danger. In 1480 two Dominicans were appointed, who established their court in a convent at Seville, ordered the arrest of several suspected persons, and the sequestration of their property. The number of prisoners soon became so great, that the court was removed to the castle of Triana, whence another edict was issued ordering every person, under pain of mortal sin and excommunication, to inform against those who had relapsed into the Jewish faith or other heresies, or who gave reason for suspecting them to be relapsed—specifying numerous indications by which they might be known. Sentences of death soon followed; and in the course of that year (1481) 298 persons were burnt alive in the city of Seville, 2000 in other parts of Andalusia, and 17,000 were subjected to various penalties. The property of those

who were executed was confiscated. Many appeals were made to Pope Sixtus IV., who protested against the arbitrary conduct of the inquisitors, and reserved to himself the right of appointing future inquisitors. In 1483 he appointed Thomas de Torquemada to the presidency of the new court, and made him likewise inquisitor-general of the kingdom of Arragon, with full jurisdiction over all other inquisitors in Spain and its dependencies. Llorente, the popular historian of the Inquisition, affirms that during the eighteen years of Torquemada's tenure of office no less than 8800 persons were burnt in Spain alone. The same author also gives an approximate estimate of the number executed under each inquisitor-general during the three centuries (from 1481 to 1808) of the existence of the Spanish Inquisition, from which it results that the total number in Spain is about 32,000 persons burnt, either alive or after being strangled, 17,000 burnt in effigy, and 291,000 condemned to various terms of imprisonment, to the galleys, or subjected to other penalties. These calculations may be exaggerated, but after making all deductions, the working of the Inquisition in Spain and in its dependencies even of the New World involves an amount of cruelty which it is impossible to contemplate without horror. The inquisitor was appointed for life, and was a distinct power between the king and the pope, and in reality independent of both; and though the rules were based upon those already noticed as being in practice by the old Inquisition, they were much more unfavourable to the accused. The rigours of the Spanish Inquisition abated in the latter part of the seventeenth century. It was abrogated by Napoleon in 1808. Ferdinand VII., after his restoration, re-established it in 1814; it was suppressed by the Cortes in 1820, partially restored in 1825, and finally abolished in 1835, and its property applied to the liquidation of the national debt. It was abolished in Portugal during the reign of John VI., about the year 1821. The inquisition which exists at Rome consists of twelve cardinals, several prelates, monks, and lawyers; but its action is confined to the censorship of the press, the trial of ecclesiastical offences, and questions of church law. The territory subject to the dominion of the pope is now the only country in which the tribunal of the Holy Office still remains.

INSANITY. The term insanity has been applied to all the forms of mental disorder. It is not possible to define it with precision. Nor can any good result follow from refining on the differences which it is said exist between lunacy, insanity, and unsoundness of mind. The legal significations attached to these terms have given rise to much confusion. Any division of insanity must of necessity be more or less artificial, but by common consent medical jurists describe five different forms—mania, monomania, dementia, amnesia or idiosyncrasy, and moral insanity. The last of these, however, is not recognized by the law.

Mania is a general insanity, marked by mental excitement, and by delusion on all kinds of subjects. There are varying degrees of the affection, depending on constitutional peculiarities. The attack is often preceded by premonitory symptoms, such as uneasiness in the head with confusion of ideas, or uneasy sensations in the stomach. Then succeed mental

agitation, sleeplessness, and paroxysms of fury alternating with calms. The sensations are frequently deranged; the appetite lost, depraved, or voracious. The abatement of the disease is evidenced by the disappearance of the hallucinations under which the patient laboured. The result of a case will depend on whether it has its origin in organic disease of the brain, or merely in functional derangement.

Monomania is characterized by the predominance of one morbid idea or a limited class of ideas, and there are great varieties in the nature of these. Sometimes there is excessive pride: the monomaniac fancies himself a god or king, possessed of boundless wealth, and having the power to scatter gifts and honours. The morbid desire to kill is one form; the fear of damnation another; and so terrible are the suffering and remorse, that the impulse to commit suicide becomes irresistible. A curious fact among this class of the insane is, that they are often unusually acute on subjects apart from their own delusions, and can reason with subtlety and ingenuity.

In dementia we have a rapid succession of ideas without connection. The patient expresses himself with untiring volubility, and passes from one subject to another. He is at one moment kind and gentle; at another furious and angry. He will for hours together repeat the same sentence or word. The reasoning and judgment are lost.

Amentia or idiocy is either congenital or accidental. The most remarkable instance of the first of these is to be found in the Cretins of the Valais, with whom it is associated with bodily ailments and malformations. Idiocy may arise accidentally from injuries of the head, the effects of violent emotions, or organic diseases of the brain.

Idiots as a rule speak little, and amentia constitutes the most hopeless form of insanity.

In moral insanity there is disorder or loss of moral principle without any delusion. There are a great many varieties and degrees of this. In some there is the irresistible desire or impulse to commit theft; in others to drink to excess; in others to acts of incendiarism. In fact, moral insanity is closely allied to crime, and it is exceedingly difficult to draw the line of demarcation between the two. The most fruitful source of this affection is a neglected or injurious education.

There are in insanity various changes in the state of the mental powers. Sensation and perception are often deranged. Morbid states of the former are insensibility to cold and fatigue; of the latter, the seeing of what does not actually exist. The attention and memory are also affected, especially in dementia, while imagination and the association of ideas, which are suspended in amentia, may be exuberantly active in the other forms of mental disorder.

Derangements of reasoning and judgment occur in insanity, but often the conclusions of maniacs are very logically deduced, if the premises be granted; at other times we find the reasoning erroneous, as well as the judgment founded on it. Sometimes both faculties are suspended or annihilated in insanity.

The change, however, which occurs in the moral faculty is the cause why the insane are not considered as responsible agents; and the rapidity with which this change occurs when insanity has manifested itself is sometimes very rapid, persons of the most

correct and virtuous habits suddenly becoming vicious in the extreme.

The causes of insanity are numerous; some of them easily traceable and others obscure. The hereditary predisposition is often very well marked, and may depend on faulty structure of the brain. Persons of a melancholy temperament, and who suffer from disorder of the digestive functions, are predisposed to the disease, and the tendency in such is greatly increased by fanatical views of religious matters. Every revival of religion has been attended with an increase of the number of the insane, and this was clearly evidenced during the last occurrence of such a revival in the north of Ireland. Further, insanity follows on indulgence in vice or debauchery; may be produced by exciting passions or violent mental exertions; by the state of pregnancy, and other physical conditions of the system. But perhaps intemperance is in this country the most frequent exciting cause.

The treatment of the insane is now conducted upon the most humane and philosophic principles. All experience goes to prove the desirability, nay necessity, of seclusion, and many of the objections which formerly existed against lunatic asylums have been removed. In a well regulated establishment restraint is very seldom resorted to, and every means are used to employ and gratify the inmates. The moral treatment is of more efficiency than the medical, and hence it is that the heads of lunatic asylums require to be men of mental vigour and capacity.

It is beyond our province in this mere sketch of the subject to dwell upon the numerous and weighty points which occur in medical jurisprudence relative to insanity. These have principally reference to the responsibility of criminals, and are attended often with great difficulty, and cause no little perplexity. The true difficulty lies in determining where eccentricity ends and insanity begins, and we cannot hope to lay down general rules which will apply to every individual case. Then there are instances in which the succession to property is disputed on the ground of mental incapacity of the testator. In the records of the law many curious cases will be found, and all the great English lawyers have endeavoured, but fruitlessly, to lay down a test by which insanity can be tried.

It only remains to add, that of late years there seems good reason to believe that, owing partially to the excitement of life, the wear and tear of business, the hurry of railway travelling, and such like causes, insanity is increasing; and as these will in all likelihood be augmented and aggravated with the progress of the times, the increase of this disease must be looked upon as one of the penalties we have to pay for our advancing civilization.

The laws relating to the insane are fully explained in the article LUNACY, and statistics, mode of treatment, &c., in LUNATIC ASYLUMS.

INSECTA, or INSECTS, invertebrate animals of the homangliate or articulate sub-kingdom, having the body divided into three portions, whence their title. [ENTOMOLOGY.] Insects are in general covered with a horny or coriaceous integument, serving as an external skeleton; they possess, when mature, three pair of legs; they are capable, for the most part, of flight, having two or four wings. The sexes are distinct, the females oviparous; they

undergo, as a common rule, three transformations from the egg to maturity. Eyes compound, with additional simple eyes or stemmata in certain groups. Circulation is effected by a pulsating dorsal vessel, provided with numerous valves, and respiration by tracheæ, which form two lateral trunks, and ramify through the body.

Insects fly, walk, leap, swim, dive, mine into the earth, bore into wood, build structures which fill our minds with astonishment, and in various ways exhibit the possession of marvellous instinctive faculties, inasmuch that many of their proceedings appear to be the result of profound reasoning. They furnish us with silk, wax, honey, lac, cochineal, and gall-nuts. Some are eaten by various tribes of men; and they furnish food to mammalia, birds, reptiles, and fishes, and to the carnivorous of their own class.

Some are remarkable for beauty, for splendour of colouring, for gracefulness and delicacy; others surprise us by the strange singularity of their forms, and others again by their natural lantern, which gleams brilliantly in the hours of darkness.

If we place an insect before us, we shall find that it is divided into three distinct parts; the head (*caput*), the thorax, and the abdomen.

The principal parts of the head are termed respectively the *clypeus* or *nasus*; the *vertex*; the *occiput*; the *genæ* or *cheeks*; the *canthus*; the *gula*. To the head belong the two compound eyes, the simple eyes, or *stemmata*, when present; the antennæ, and seven portions of the mouth called *trophæ*.

The mouths of insects are either mandibulate, formed for biting, or haustellate, formed for suction.

In a mandibulate mouth, the seven portions, collectively termed *trophæ*, consist of a *labrum*, or upper lip; a *labium*, or under lip; two *mandibulæ*, or jaws; two *maxillæ*, or under jaws; and a *lingua*, or tongue. To the maxillæ are attached a pair of feeders called *maxillary palpi*; and a similar pair are also attached to the labium, or under lip; these are the *labial palpi*. The *labrum* is usually movable, and articulated to the clypeus, terminating the head anteriorly; it is opposed to the *labium*, and their joint use appears to be to keep the food in its proper place, while the jaws work upon it. The *labium* is divided into three portions; the *palpiger*, the *mentum*, and *stipes*. The labial palpi generally consist of two articulations, exclusive of their basal attachment. The *mandibulæ* or mandibles are used for seizing and biting; when viewed from above beneath, they generally represent a figure more or less approaching to a triangle; are externally convex, but internally concave, the concave surface being furnished with serrations, or tooth-like processes. As mandibulate insects vary in their food, some being frugivorous, others granivorous, others herbivorous, others lignivorous, and others again carnivorous, there is great variation in the form and development of the *mandibulæ*.

With respect to the *maxillæ*, or under jaws, it may be observed that, exclusive of the maxillary *palpus*, each *maxilla*, besides its true and effective part, or *lobus inferior*, has an appendage sometimes rudimentary, sometimes wanting, but often composed of two or three joints, and resembling an additional *palpus*. The *maxillæ* appear to assist in turning

the food about during the operation of the mandibles. The basal joint of the *maxillæ*, on which it moves, is called the *cardo*, or hinge. The tongue is situated within the *labium*, or lower lip, and sometimes emerges from it. In many cases it constitutes an organ for the collecting of food, which it transmits to the gullet. For an account of the antennæ of insects see ANTENNÆ.

Now, however different the mouths of haustellate insects may be from the mouths of mandibulate insects, still the difference is one of modification only. The parts are the same, but newly fashioned and proportioned. Indeed, among the *mandibulata* we find a remarkable modulation in the mouth of some insects, as the bee, which laps the honey of flowers. In the bee and its allies, the mandibles are large and powerful; the *labrum* varies in shape, but is distinct. The maxillæ are elongated, and modified into a sheath for the tongue, and are affixed to the mentum, or base of the labium, with small palpi. The labium is elongated, and articulates with the tongue, which is carried from it. The tongue, which in most mandibulate insects is short, is long and slender in haustellate insects. The labial palpi have four joints, the most which these organs ever have, and they are remarkable for exceeding in length the maxillary palpi, which are ordinarily the longest. The first two joints are compressed, and set on below the apex of the second joint. The tongue, moreover, is sheathed at its base with two membranous appendages, found also in predaceous beetles, and termed *paraglossæ*. The upper part of the tongue is cartilaginous, and remarkable for a number of transverse rings; it is moved by numerous muscles. Below the middle is a membrane longitudinally folded when not in use, but capable of being distended to a considerable size; this membranous bag receives the honey which the tongue laps from the flowers.

As examples of the haustellate insects, in which the mouth is modified for suction, we may mention the Butterfly, the Aphid, the *Cimex lectularius*, the Flea, the Fly, the Tabanus, the Gnat, Mosquito, &c. The vast variety of modifications presented by the suctorial mouth of haustellate insects are fully detailed in Kirby and Spence's 'Entomology.'

The thorax is composed of three segments consolidated together, respectively named *prothorax*, *mesothorax*, and *metathorax*; these terms, however, rather apply to the upper than the under surface, for the under part of the *prothorax* is called *prosternum*, of the *mesothorax*, *mesosternum*, and of the *metathorax*, *metasternum*. The prothorax carries the first pair of legs, the mesothorax the second pair, and the first pair of wings, or in their place the wing-cases (*elytra*); the metathorax supports the third pair of legs and the second pair of wings. Dipterous insects, which have only two wings, are furnished with *halteres*, or poisers, and above them a little scale or winglet (*alula*), the use of which is not very clear.

The *limbs*, variously modified for running, leaping, swimming, burrowing, and even for adhesion, by means of suckers, to panes of glass, the ceilings of rooms, &c. (as we see in the common fly), consist of five principal parts, viz., the *coxa*, or hip, next to the body; the *trochanter*; the *femur*, or thigh;

the *tibia*, or shank; and, lastly, the *tarsus*, or foot, never composed of more than five joints, and often ending in two hooked claws, called *unguiculi*, in addition to suckers.

The abdomen consists of nine segments. The respiratory spiracles, or *stigmata*, are disposed in regular succession along the sides of the thorax and abdomen; the aerating tubes ramify throughout the body, and run along the nervures of the wings.

The digestive system of insects is well developed, and consists of an intestinal canal, in which a crop, gizzard, stomach, and small intestine are generally distinct; and, as in the higher orders of animals, these parts vary according to the nature of the food.

Insects are either *ametabolous*, or *metabolous*. In the former the larva resembles the perfect insect, yet it wants wings if the perfect insect be winged; the pupa in this case has their rudiments; it runs about and eats. The Cockroach is a familiar example of an *ametabolous* insect; so is the Water-boatman (*Notonecta*), and so are Crickets, Grasshoppers, Locusts, &c. Under this section Burmeister places three orders, viz., *Hemiptera*, *Orthoptera*, and *Dictyoptera*, which latter might be incorporated with the preceding.

In *metabolous* insects the larva consists of thirteen segments, either with or without legs; the pupa is inactive, or if it moves, it takes no food. To this section belong Beetles, Butterflies, Moths, Flies, Gnats, &c.

The larvæ of many insects, as the Gnat, the Dragon Fly, &c., are aquatic in their habits, but furnished with an apparatus which enables them to respire air. Some weave cocoons of silk, some bury themselves in the earth, and some suspend themselves in order to pass through the pupa state.

The legs of larvæ, or caterpillars, are divided into two series, viz., the *true* or *persistent*, and the *prolegs*, which are temporary. The true legs consist of three pairs attached respectively to the first three segments of the body, which constitute the future thorax. The prolegs are soft, short, and conical; they vary in number in different species. The caterpillar of the common cabbage butterfly has five pairs; and it is to be observed that, when five pairs are present, none are found on the fourth, fifth, tenth, or eleventh segments, but a pair respectively on the sixth, seventh, ninth, and twelfth segments, the twelfth being the last.

With respect to the various systems upon which insects have been classified, the student must consult the works of Linnaeus, Fabricius, Burmeister; Latreille, in 'Règne Animal'; Kirby, Spence, and Rymer Jones, 'Structure of the Animal Kingdom'; and the productions of the Entomological Society. [BOMBYCIDÆ; COLEOPTERA; DIPTERA; HEMIPTERA; ORTHOPTERA, &c.]

INSECTA, FOSSIL. Until within a few years the occurrence of insects in a fossil state could only be substantiated by reference to a small number of localities, situated (as at Aix in Provence) among lacustrine tertiary strata, or (as at Stonesfield in Oxfordshire, and Solenhofen in Franconia) among marine oolitic beds. But Mr. Prestwich has added traces of coleoptera from the coal formation of Coalbrook Dale, and Mr. Strickland parts of neuroptera from the lias of Warwickshire, Dr. Buckland ob-

tained neuroptera from the oolite of Stonesfield, and Mr. Brodie portions of insects belonging to various natural orders from the lias of Somersetshire, Gloucestershire, and in the Wealden deposits of the Vale of Wardour in Wilts, and the Vale of Aylesbury.

Still the number of fossil insects, whether we estimate individuals or species, is very small compared to the probable number of anciently existing races; a circumstance quite explicable by reference to the phenomena which are now taking place in nature; for of upwards of 12,000 British species of insects there is reason to believe that but a very minute proportion is buried and preserved in lacustrine, estuary, or marine deposits now in progress.

No doubt vast numbers of insects pass from the shore and fall in the sea, as we learn from the first voyage of Cook, who sailed through myriads of insects, some on the wing and others in the water, even thirty leagues from land off the coast of South America; but few of these escape the watchful finny races, or ever reach the bottom of the sea.

In like manner we find land insects heaped in profusion by winds on certain tracts of fresh water, and borne down the course of rivers by inundations: and these cases, by the aid of particular suppositions, such as evaporation or slow draining off of the water, may offer the nearest analogy to the facts actually observed in the greater number of insect deposits.

INSECTIVORA, a group or order of lissencephalous mammalia, feeding chiefly upon insects and their larvæ. The Shrew, the Hedgehog, and the Mole are familiar examples. [CARNIVORA.] Also, an order of birds in the ornithological system of Temminck.

INSESSORES, the name given by Mr. Vigors to the *Perchers*, the second order of Birds in his system; and as the families of which it is composed are very numerous, he classes them in comprehensive sections or tribes, which he thus denominates:—*Fissirostres* (Cuvier), *Dentirostres* (Cuvier), *Conirostres* (Cuvier), *Scansores* (Auct.), *Tenuirostres* (Cuvier).

The *Fissirostres*, according to Mr. Vigors, include the *Meropidae*, the *Hirundinidae*, the *Caprimulgidae*, the *Todidae*, and the *Halcyonidae*.

The *Dentirostres* include the *Muscicapidae*, the *Laniidae*, the *Merulidae*, the *Sylviidae*, and the *Pipridae*.

The *Conirostres* comprise the *Fringillidae*, the *Sturnidae*, the *Corvidae*, the *Buceridae*, and the *Loxiidae*.

The *Scansores* consist of the *Ramphastidae*, the *Psittacidae*, the *Picidae*, the *Certhiidae*, and the *Cuculidae*.

The *Tenuirostres* are composed of the *Nectariniidae*? *Cinnyridae*, *Trochilidae*, *Promeropidae*? and *Meliphagidae*?

INSOLVENT is, literally, a man who cannot pay his debts. The term in England was formerly confined to non-traders; persons in business who could not meet their liabilities being called **BANKRUPTS**. But a man is not properly called insolvent till he has been found to be so by the process to which he is liable under the insolvent acts, if he does not pay his creditors. The law as to insolvency formerly applied to those who did not come within the operations of the law relating to Bankruptcy.

The Insolvent Law of England was administered

by commissioners appointed by the Crown, in a court called the Insolvent Debtors' Court, and three of the commissioners from time to time made circuits, and gave their attendance at the assize towns or places where prisoners might be ordered to appear.

The general object of the law as to insolvency was to release the debtor from prison, to free his person from liability as to debts contracted previous to his discharge, but to make all his present and future acquired property available for the benefit of his creditors. Where new creditors had a claim on the insolvent's subsequently acquired property, which was of such a nature that it could not be taken in execution, it was necessary to apply to a court of equity, which, in administering such estate of a deceased insolvent, would pay the creditors subsequent to the insolvency first, and then the creditors prior to the insolvency. Of course this law is still applicable to cases under the Insolvent Acts.

The Act 7 & 8 Vict., c. 70, which came into operation the 1st September, 1844, and is entitled 'An Act for facilitating arrangements between Debtors and Creditors,' is of the nature of an insolvent act. Under this act a debtor who was not subject to the Bankrupt Laws might apply by petition to a court of bankruptcy, and obtain protection from arrest, provided his petition be signed by one-third in number and value of his creditors. Under Lord Westbury's Act of 1861 the distinction between insolvency and bankruptcy no longer prevails; but the whole Bankruptcy Law will be revised and modified in the present session (1866).

The law of debtor and creditor has been a difficulty in all countries. In England an insolvent debtor might, in certain cases, be subjected to the operation of the Bankrupt Laws. [BANKRUPT.] If he could not claim the benefit of the Bankrupt Laws, he was subject to the law that related to insolvent debtors.

Formerly there were two kinds of arrest in civil cases—that which took place before trial, and was called arrest on mesne process; and that which takes place after trial and judgment, and is called arrest on final process. In the arrest on mesne process it was only necessary for the plaintiff to make an affidavit that the cause of action amounted to 20*l*. (7 & 8 Geo. IV. c. 71), upon which he could sue out a writ called a *capias*, which was directed to the sheriff, who thereupon gave his officers a warrant for seizing the alleged debtor. The Statute 1 & 2 Vict., c. 110, ss. 2, 3, 4, 5, 6, enacted that no person can be arrested for alleged debt before a judgment has been obtained against him, unless it can be shown to the satisfaction of a judge of one of the superior courts that the plaintiff has a cause of action against such person to the amount of 20*l*. or upwards, and that there is probable cause to believe that the defendant is about to quit England. A defendant might also be arrested upon mesne process when he has received an unfavourable judgment in the court for the relief of insolvent debtors (1 & 2 Vict., c. 110, s. 85).

Arrest in execution is therefore now the only arrest that is of any practical importance: it means the arresting of a man after a court of justice has decided that he owes a debt. On this subject there has been difference of opinion.

The whole jurisdiction of the Insolvent Court was, by the Bankruptcy Act of 1861, transferred to the Court of Bankruptcy, and there is now no distinction between bankrupts and insolvents; but this Act having failed in operation, considerable changes will probably be introduced during the present session (1866). [BANKRUPTCY.]

In Scotland the being in a state of insolvency has the same effect in regard to questions of stoppage in transitu, and others connected with sale and delivery, as it has in England. The word is often used in connection with the bankrupt law, because being insolvent is one of the ingredients of Notour Bankruptcy. *Cessio Bonorum* is the name of the procedure that in Scotland stands in place of the old insolvency relief system in England.

INSPECTOR OF FACTORIES. [FACTORIES.]

INSPECTOR OF SCHOOLS. [SCHOOLS.]

INSPECTOR-GENERAL, a military office, the duties of which are the periodical inspection of the corps in their districts, and the pointing out of deficiencies in their arms, dress, drill, or deportment; the corps being under the command of its own officers, and not of the inspector-general. In the army estimates for 1865-66 the pay of the Inspector-general of Engineers and Director of Works is 1874*l*. per annum, of the Inspectors-general of Cavalry, of Infantry, of Artillery, each 691*l*. 19*s*. 7*d*., and of Volunteers 691*l*., in addition to regimental, unattached, or half-pay. There are also two Inspectors-general of Militia at 347*l*. per annum, with allowances for servants, forage, and lodgings; and six Inspectors-general of Medical Establishments, who constitute the highest grade of surgeons, at 821*l*. a year each.

There are also inspecting field officers, inspectors of musketry, eleven inspectors of volunteers, five inspectors of military schools, and inspectors of fortifications.

INSTALLATION, in church law, means the process by which a clergyman is formally put in possession of his office, and by which he is empowered to exercise its functions, and enjoy its honours and emoluments. The ceremony is called 'enthronization' when a bishop is installed in his office; 'induction' for a rector. Installation in its strictest sense only refers to the office of a canon or prebendary; but the word is also used generally for a formal introduction to any office.

INSTANCE, COURT OF. [ADMIRALTY COURTS.]

INSTINCT is a natural impulse to certain actions which animals perform without deliberation, and without having any end in view, and without knowing why they do it. That the spontaneity of instinct operates unconsciously is fully established by observation. A calf butts with its head before its horns are grown; and the hen broods over the eggs of another species, or even simulated eggs, as patiently as over its own. Lastly, children in certain states of the body are observed to devour eagerly chalk and other earths which are the proper remedies for the disease, although they can have no knowledge of their beneficial nature.

Instinct differs from intellect by the unerring certainty of the means it employs, the uniformity of its results, and the perfection of its works prior to and independent of all instruction or experience; and

lastly, by the pursuit of nothing beyond what conduces directly either to the welfare of the individual or the propagation of the kind. But the arts of rational creatures proceed slowly through diversified and oft-repeated experiments, while the means they employ are always various and seldom the best.

INSTITUT NATIONAL, or *Institute of France*. The various academies of learning in France having been dispersed during the first storms of the Revolution, a decree of the Republic, dated October, 1795, established a national academy, for the promotion of the arts and sciences, called the *Institut National*. It was at first divided into three classes—viz., physical and mathematical sciences, moral and political sciences, and literature and the fine arts. Each class consisted of a certain number of members residing at Paris, and a number of associates in different parts of France, with a small number of foreign honorary members. Napoleon I., when he was made first consul, reorganized the *Institut*, suppressing the class of moral and political sciences, and forming the four classes of—I., physical and mathematical sciences, divided into eleven sections, viz.: geometry, mechanics, astronomy, geography and navigation, general physics, chemistry, mineralogy, botany, veterinary surgery, anatomy and zoology, and medicine and surgery. This class consisted of sixty-two resident members, who could appoint one hundred correspondents, including foreigners. II. French language and literature, consisting of forty members, like the old *Académie Française*. III. Ancient history and literature, corresponding to the old *Académie des Inscriptions et Belles Lettres*, and consisting of forty members, eight foreign associates, and sixty correspondents. IV. Fine arts, divided into five sections, painting, sculpture, architecture, engraving, and music. This class consisted of twenty-eight members, eight foreign associates, and thirty-six correspondents, native and foreign. An annual allowance of 1500 francs was fixed for each resident member, and a salary of 6000 francs to each of the perpetual secretaries, of whom there were two for the first class, and one for each of the other three. Annual prizes were also awarded. This arrangement continued during the Empire, except that the *Institut* took the name of Imperial. After the Restoration, Louis XVIII., by an ordinance, 21st March, 1816, without changing the arrangements of the departments of each class, restored the old names of *Académie des Sciences*, *Académie Française*, *Académie des Inscriptions et Belles Lettres*, and *Académie des Beaux Arts*, giving to each a more independent organization, but still keeping them united in one academical body called the *Institut*. Louis Philippe, by a royal ordinance, October 26, 1832, added a fifth class, or *Académie des Sciences Morales et Politiques*. This constitution has been continued under the Emperor Napoleon III. These various classes or academies have published numerous valuable memoirs and reports. Each year a sum is voted by the French government for the general fund of the *Institut*, and from this fund are paid the allowances of members, salaries of secretaries and other officials, several prizes, and the expense of experiments and printing. Many eminent Englishmen are foreign associates, and a still greater number are correspondents of the Institute.

INSTITUTES, the title of a book, in the old

civil law of the Romans, which contained the elements or principles of their law. They constituted the great body of the *corpus juris civilis*, and were compiled by order of the Emperor Justinian for the use of students, and as a book of reference on law questions.

INSTITUTION. [ADVOWSON; BENEFICE.]

INSTRUMENTS, MUSICAL, may be divided into four sorts. 1. *Keyed*, as the organ, pianoforte, harmonium, &c.; 2. *Stringed*, as the violin, harp, guitar, &c.; 3. *Wind*, as the flute, clarinet, horn, &c.; 4. *Percussion*, as the drum, triangle, cymbals, &c. There are only two ways of producing musical sounds, one by the vibrations of a fixed elastic body, such as the string of the violin or pianoforte, the reed of the hautboy, &c., or by the vibrations of a confined column of air put in motion by a stream of compressed air, as in the flute, and all kinds of organ pipes. The various instruments are described under their respective names.

In the year 1864 the exports of musical instruments from the United Kingdom—chiefly to Australia and India—were valued at 167,851*l.* The value of the imports in the same year was 224,249*l.*, nearly two-thirds coming from France.

INSULATORS. When a body containing an amount of electric fluid or free caloric is surrounded by non-conductors, and its contact with other bodies thereby prevented, it is said to be *insulated*, and the non-conducting bodies are called *insulators*. The most effectual of these are, caoutchouc, silk, glass, dry fur, gutta-percha, sulphur, shellac, and dry air.

INSURANCE, FIRE. Associations for securing individuals from the ruinous consequences of accidents beyond their own control now form almost a necessary part of our social institutions. Among such combinations for the security of individuals, companies for assuring the owners of property from loss arising from fire are among those of most obvious utility, and have long been established in this country.

It might have been expected that the great advantage to society of individuals providing against loss, by means of trifling annual payments, would have been so far acknowledged by the British legislature as to prevent the imposing of a tax upon prudence. Such, however, is not the fact, and a duty is still levied at the rate of 1*s.* 6*d.* per cent. per annum upon the amount of property insured against destruction by fire, which rate is, in most cases, equal to 100 per cent. upon the premium (1*s.* 6*d.* per 100*l.*) demanded by the insurance offices for non-hazardous property, such as ordinary dwelling-houses; which premium is found sufficient to cover all losses, as well as to defray the expenses of management, and to afford an adequate return to capitalists who embark their property in the undertaking. For property considered hazardous, such as cotton mills, sugar refineries, and theatres, higher premiums are, of course, charged; and some kinds, such as powder mills, are entirely declined.

Till last year (1865) the tax was 3*s.* per cent., but as such an impost undoubtedly prevented many persons from insuring who would otherwise have done so, it was, after persistent efforts in the House of Commons on the part of Mr. Hubbard, reduced to 1*s.* 6*d.*, and it is probable that it will eventually be repealed.

The amount of revenue derived from the fire insurance duty of late years has averaged 1,550,000*l.* per annum—the property insured being valued at about 1,100,000,000*l.* There can be no doubt that the reduction of the duty will have the effect of rapidly increasing the latter amount.

During a period of distress experienced by the agriculturists, the landowners and farmers of Great Britain obtained in 1833 an advantage over other classes of the community by the repeal of the duty upon insurance of farm produce, farming stock, and implements of husbandry (3 & 4 Will. IV., c. 23.)

Cases occur in which frauds are practised by parties insuring for more than their property is worth; and there are also cases in which property has been burnt by insolvent persons in order to obtain the insurance money.

Fire insurance policies are too well known to require description here, but insurers cannot be too careful in filling them up, for an apparently unimportant misstatement or reservation is quite sufficient to render it void if the company chooses to be at all arbitrary.

INSURANCE, LIFE, OR REVERSION. By a reversion, in the widest sense, is meant a right of property the enjoyment of which is to commence at some future period, fixed or depending on contingencies, and is to continue either for ever or during a term either fixed or depending on a contingency: anything, in fact, which is to be entered upon, or which may be entered on, at a future time, is a reversion in books which treat on the value of property. The legal sense of the word is more restricted.

Thus an assurance of 100*l.*, or a contract to pay 100*l.* at the death of a given individual, is 100*l.* in reversion to the executors of that individual. Our object in this article is to treat of this most common species of reversionary contract, life insurance, or assurance.

The value of a reversion depends in a very easy manner upon the value of the corresponding annuity; that is, any given sum, say 100*l.*, to be received when a given event arrives, depends for its value upon that of 100*l.* a year to be received till the event arrives. Suppose, for example, that money makes five per cent., and that an annuity, say upon a life, is worth fourteen years' purchase: that is, 100*l.* paid a year hence, and again two years hence, and so on as long as the life lasts, is now worth 1400*l.* Required the value of 100*l.* to be paid at the end of the year* in which the life drops. We must now reason as follows:—Suppose a perpetual annuity of 100*l.* a year is to be enjoyed by A during his life and by his legatees after him. By hypothesis A's portion is now worth 1400*l.*, and (money making five per cent.) the annuity for ever is worth twenty years' purchase, or 2000*l.*; consequently the legatee's interest is now worth 2000*l.* — 1400*l.*, or 600*l.* But at the end of the year of death the legatee will come into 100*l.* current payment, and a perpetual annuity worth 2000*l.*; for the remainder of a perpetual annuity is also a perpetual annuity: his interest will then be worth 2100*l.* Hence we have ascer-

tained that 2100*l.* at the end of the year of death is now worth 600*l.*: and the rule of three then gives the value of any other sum: thus 100*l.* at the end of the year of death is now worth $600 \div 21$, or 28*l.* 11*s.* 5½*d.* Hence the following easy

Rule.—To find the value of a given reversion, subtract the value of the same annuity from that of a perpetual annuity, and divide the difference by one more than the number of years' purchase in a perpetual annuity: or multiply the excess of the number of years' purchase in a perpetual annuity over that in the life annuity by the reversionary sum, and divide as before.

Next, to find what premium should be paid for the reversion. A premium differs from an annuity in that a sum is paid down, and also at the end of every year: consequently it is worth one year's purchase more than an annuity. In the preceding question, the annuity was worth fourteen years' purchase; consequently the premium now is worth fifteen years' purchase. But the present value of all the premiums is to be also the present value of the reversion, or 28*l.* 11*s.* 5½*d.*, whence the premium should be the fifteenth part of this, or 1*l.* 18*s.* 1*d.* Hence to find the premium, divide the present value of the reversion by one more than the number of years' purchase in the life annuity. But when, as most commonly happens, the premium is wanted without the present value, the following is an easier

Rule.—Divide the reversionary sum separately by one more than the number of years' purchase in the perpetual annuity, and one more than the number of years' purchase in the life annuity: the difference of the quotients is the premium required. Thus, if in the preceding example we divide 100*l.* by 20 + 1 and by 14 + 1, or by 21 and 15, we find 4*l.* 15*s.* 3*d.* and 6*l.* 13*s.* 4*d.*, which differ by 1*l.* 18*s.* 1*d.*, the same as before.

The life we have been tacitly considering, when we talked of an annuity being worth fourteen years' purchase, at five per cent., is one of about thirty-six years of age. The first impression must be, that the proposed premium is ridiculously small. Make it up to 2*l.*, and it will be fifty years before the premiums reach 100*l.* Some such consideration must have moved the law officers of the crown in 1760, when they refused a charter to the Equitable Society, then charging a premium of about 4*l.* at the age of thirty-six, on account of the lowness of their terms. But it is to be remembered that those who receive the premiums are to invest them immediately at five per cent., and are to invest the interest, thus making compound interest; persons aged thirty-six live, one with another, about thirty years, which is sufficient time for the premiums, with their interest, to realize 100*l.* for each person, one with another.

We now show the manner in which a simple result of calculation answers its end. To simplify the case, suppose an office starts with 5642 individual subscribers, each aged thirty years, the mortality among them being that of the Carlisle Table. The bargain is for a short assurance, as it is called, of twenty years, and of 1000*l.*; that is to say, the executors of each one who dies within twenty years are to receive 1000*l.* at the end of the year of death. Money makes three per cent. once a year. According to the table, then, there are 57, 57, 56,

* Assurance Companies usually pay in a few months after proof of death, which gives a trifling advantage to the assured, not worth considering in a very elementary statement of the question.

&c., deaths in the successive years, and the following is the result, the proper premium being calculated at 11*l.* 12*s.* 3½*d.* each person, or more exactly 11,614*l.* 16*s.* for 1000 persons. It is supposed that there are no expenses of management. At the outset the office receives 65,530*l.* from the 5642 persons assured: this is immediately invested at three per cent., and yields 1966*l.* by the end of the year, making 67,496*l.* But at the end of the year the claims of the executors of fifty-seven persons who have died during the year are to be satisfied, which requires a disbursement of 57,000*l.*, reducing the society's accumulation to 10,496*l.* The contributors who are left, 5585 in number, now pay their second premiums, 64,869*l.*, so that, these being immediately invested, the company has 75,365*l.* at interest during the second year. This yields 2261*l.*, so that by the end of the year 77,626*l.* is accumulated. Then comes the demand of 57,000*l.* on behalf of fifty-seven contributors deceased during the year, which reduces the accumulation to 20,626*l.* This is more than it was at the same time last year. In this way the company goes on, accumulating to an amount which would lead a person unacquainted with the subject to conclude that the premium must be too large; in fact, ten years give an accumulation of 91,809*l.* But now the state of affairs begins to change; the contributors have been diminishing, while the claims have been increasing, until the yearly incomes no longer equal the outgoings. The accumulations then come in to make good the difference, in such manner that by the time the remaining contributors come to be fifty years of age, and the claims of sixty-one who died in their fiftieth year have been satisfied, there only remains 8*l.* of the 91,809*l.*; and this 8*l.* is merely the error arising from omitting shillings, &c., in the calculation. Something of the same kind must take place in every office which dies a natural and solvent death; the only difference being that, when new business ceases, instead of a number of contributors all of the same age, and under similar contracts, both ages and contracts vary considerably.

Life Assurance Companies are divided into three classes—Mutual, Proprietary, and Mixed.

A Mutual Company is one in which the members stand bound to each other, and constitute the company themselves. In such a company no capital is, generally speaking, raised at the outset, except a small sum for necessary expenses at starting. This, however, is not necessarily the feature of a mutual company; for if its members choose to constitute themselves an investment company as well as an assurance company, they may, without losing their mutual character, require every assurer to be also a shareholder. In a mutual company the profits, of course, are divided among the assured.

A Proprietary Company is one in which a body of proprietors raise a capital and pledge it for the payment of claims, in case the premiums are not sufficient: for this security they receive, in addition to the interest of their own capital, the profits of the assurance business. It has long been proved that, with proper tables of premiums, and a fair amount of business at starting, this capital is an unnecessary security; and the only reason which could now make such an office desirable would be the lowness of its

premiums. Of course it matters nothing to the assured how they are paid, as long as they are paid; the capital may be diminished, but the assurer dreads nothing except its exhaustion before his turn comes. This must be the sole consideration with a person who is tempted by low premiums to a purely proprietary office: the nominal capital signifies nothing; it is upon the amount of assurance to which it (with the premiums) is pledged that the solvency of the office depends. Generally speaking, however, we believe it will be found that the purely proprietary offices have not allowed themselves to run much risk.

A Mixed Office is one in which there is a proprietary company, which does not take all the profits, but a share, the rest being divided among the assured. The only good effect of the capital upon the condition of the assured in such a company is this—that the directors, having fixed capital as well as premiums, may justifiably seek for investments which a mutual company must avoid. Having the capital to make good purely commercial losses, they may perhaps attempt to get a higher rate of interest, and of course take more risk of loss; the assured, who are sharers in the whole of the profits, since the profits of premiums and profits of original capital are not distinguished, come in for their share of the extra profits of the capital. But no such attempt at gaining higher interest by secondary securities should be made until a sum sufficient (with future premiums) to meet all claims is invested in the very safest securities which the state of society offers.

It would, of course, be quite out of our province to attempt to define the respective merits of the three different systems; but it is an unquestionable fact that well-established mutual offices have, of late years, enjoyed the largest share of public support. It is estimated that the sum for which existing life assurance offices of all kinds in Great Britain are now liable is considerably over 200,000,000*l.*, and that the amount paid annually as premiums exceeds 6,000,000*l.*

In the construction of a table of premiums, three points must be left to the judgment of the constructor—the rate of interest, the table of mortality, and the addition to be made for expenses of management and probable fluctuation, or discrepancy between the predictions of the table and the events which actually arrive.

The rate of interest to be assumed is an element which requires the greatest caution. It must be a rate which can actually be made, and therefore prudence requires that it should be something below that which may reasonably be looked for. To show how powerful an agent it is, we shall repeat the example already given, of the 5642 insurers for twenty years, on the supposition that the office which charges as for 3 per cent. finds itself able to make 3½ per cent., and it will appear that the office leaves off with an accumulation of 15,441*l.* nearly; and, if it be lucky during the first years, it may be said to be safe against any fluctuation for which there is an even chance, by the increase of interest alone.

Take what amount of precaution we may, an office must, at first starting, depend upon something either of capital or guarantee. Even a mutual office

must raise something at the outset. Tables must be constructed with very large additions to the calculated premiums, which are to meet the very earliest contingencies alone; indeed it is difficult to say what addition would be too large. But this point it is unnecessary to insist on, since we can hardly suppose it possible that any set of men would found an office with no resource except premiums from the very commencement. Supposing proper precautions to be taken, we imagine that an addition of 25 per cent. to premiums calculated from the Carlisle Tables at 3 per cent. per annum, is sufficient to place a mutual office upon a sound footing, and to give a very great prospect of a return in the shape of what is called profit. It never has been found that an office charging at this rate has been without surplus of some kind.

This surplus has been called by the inaccurate name of profit, whereas it is really that part of the security against fluctuation of interest and mortality which has been found to be unnecessary. In mutual offices it is to be returned to the assured in an equitable manner; in purely proprietary offices it is really profit to the proprietors, whose capital has yielded them the ordinary interest, since, by hypothesis, none of it has been necessary to meet claims, and they therefore share among themselves the residue of the premiums. It is impossible to avoid this surplus in a well-constituted office; for the mathematical line which separates surplus from deficiency cannot be expected to be attained, so that those who would not have the latter must take care to have the former. It is usual among the offices to adopt a plan for increasing this surplus, which we will now describe.

Two rates of premiums are adopted, the one less than the other. Those who pay the higher rate are to have a share of the surplus: those who pay the lower rate have nothing but the nominal sum for which they assure. If the table of lower rates yield a surplus (which it is supposed it will do), that surplus goes to augment the final receipts of those who assure for profits.

The expenses of management are relatively trifling when the office has obtained a large amount of business, but they bear heavily on young offices during the first years.

The rates of mortality are generally based upon what are called 'the Carlisle Tables'—having been derived from the observations of Dr. Heysham, of Carlisle, from the nine years 1779 to 1787 inclusive, which are generally admitted to be a correct representation of *healthy* life in England. There are certain tables called 'Commutation Tables,' the invention of Mr. George Barrett, which greatly facilitate the necessary calculations in connection with life assurance. They are described in the 'Treatise on Annuities,' published by the Society for the Diffusion of Useful Knowledge. Much valuable information on life assurance may also be found in the Transactions of the Institutes of Actuaries, published quarterly; but perhaps the best work on the whole subject is 'The Assurance Guide and Handbook' (London: W. S. D. Pateman, 1857), the anonymous author of which has no leaning to any particular offices or systems.

The benefits of life assurance (which is in reality

a large combination of small sums for the purpose of beneficial investment, with a contract among those who invest that the inequalities of life shall be compensated so that those who do not live their average time shall be sharers in the good fortune of those who exceed it), and the moral considerations which should induce every friend of his species to promote and extend it, are of course not the particular motives which actuate the founders of such offices, though no doubt they have them in the same degree as others. To bring business to a particular office becomes their interest and their object; and every possible mode of investment has been held out to engage the attention and suit the particular objects of the assurer. To this of course, in general, we do not object: for instance, when a company proposes twenty different kinds of assurances, it is enough for the public that the terms of each kind are sufficiently high, and not too high. But it sometimes happens that among the proposals which are held out for the assurer's acceptance are to be found some which altogether militate against the moral principles of assurance; these are prudence, foresight, and present self-denial for the attainment of ultimate prosperity and of present security against the chances of life. When an office announces that it is willing to leave a part of the premium in the assurer's hands, on his paying interest for it in advance, the office in the meanwhile holding the policy as a security—what is it but enticing a person to assure for more than he can afford to do, and to borrow money for the purpose of paying the premiums? The office may, with caution, make itself secure; but it throws upon the customer the strong probability of future disappointment. When the time comes for thinking of the repayment of the advances which the office has virtually made, the assurer will frequently find himself obliged to sell that policy to the office which he had counted upon for the benefit of his family. Now out of the purchase-money must be deducted the sums in arrear to the office (upon which interest has always been paid in advance); and when the assurer comes to put his balance against what he has actually paid, he will see that he never did a more imprudent act. The office is not to blame for anything but having thrown the original offer in his way; they have only lent him money on the same terms as they would have lent it to others; and they may say, and truly, that it was his own fault if he engaged in an imprudent speculation. But is it not, then, a fault to entice others to imprudence, knowing how much more easily men are induced to be imprudent than to be prudent?

In 1865 the 27 and 28 Vict., c. 43, was passed, which cannot fail to greatly influence the future of life insurance among the working and lower classes. It is known as the *Government Annuities Act*, and under its provisions the postmaster-general may insure the life of any person between sixteen and sixty years of age, and guarantee them direct government security for the payment of the sums insured immediately after their death. These sums must not exceed 100*l.*, or be less than 20*l.*; but Mr. Tidd Pratt, the registrar of Friendly Societies, and therefore a first-class authority on the subject, thinks that to make the plan thoroughly useful for the humbler classes the latter sum should be reduced

to 10l. Immediate and deferred annuities, to any amount not exceeding 50l. a year, may also be granted, under the same Act, to any person not less than ten years of age. Insurances may now be effected at nearly every post-office in the kingdom, where also copies of the plainest of instructions may be obtained gratuitously, so that it is here quite unnecessary to enter into any further details of the scheme.

INSURANCE, MARINE. [SHIPS.]

INSURANCES, LAW OF. *Fire.*—In order to insure property against fire it is necessary that the insurer must have some interest in it, so that there may be no inducement to commit arson. As before stated, in the description of the premises and goods the greatest care should be taken, and the premises must not be materially altered during the risk, otherwise the policy will be void. A person in lodgings may insure his goods, and call the house his 'dwelling-house' for the purpose. When a fire happens full particulars of the damage done must be sent to the office, and it is only the *actual* loss which can be recovered. Thus if a man is insured for 1000l. and a fire takes place in which only 100l. worth of property is destroyed, he can only recover 100l. In the case of property insured in several offices the insurer can only recover the amount of damage once. He can claim it from either office, if each policy cover the whole value of the loss, and the party who pays can then recover from the other offices a proportionate part of the amount.

Life.—As in the case of fire, no person can insure another's life unless he has some pecuniary interest in it. Thus a creditor may insure the life of a debtor, a wife that of a husband, or a husband that of his wife. It is sufficient that the interest existed when the policy was first accepted; so that a creditor may recover even after the debt has been paid, if he has kept up the policy. A person may insure his life in as many offices as he thinks proper, and his executors will recover the full amount insured from each, regardless of the rest. Great care should be taken in answering the questions proposed by the company, as any material misrepresentation or reservation renders the policy void in the eye of the law. If a person commits suicide or is hanged the policy is also void, unless, in the case of suicide, he was in a state of insanity at the time.

In both fire and life insurances particular attention should be paid to the interval of from fifteen to twenty-one days which is generally allowed after the expiration of the year to pay up the premiums, as it is dangerous to run the risk of fire or death in that interval, unless the policy expressly states the insurer will be just as liable as if it had happened previously.

INTAGLIO, an Italian word, composed of *in* and *tagliare*, to cut. It is a term of art applied to small works of the gem class, in which the design is indented or engraved, to distinguish them from those in which the subject or device is raised, called *Cameos*.

The Greeks carried this branch of the fine arts to the same perfection which their genius and feeling for the beautiful enabled them to reach in all others to which they devoted their attention; but we do not trace its existence among them to a very remote date. We have no information respecting the process by which the ancient intagliatori (or sculptores)

executed works which are now justly referred to as the best examples of the art. The lathe is not described by any ancient writer; but the works themselves seem to afford evidence of its employment, and Pliny refers to the invention of an instrument which he calls 'tornum' ('Nat. Hist.,' lib. vii.), which may fairly be supposed to mean a turning machine or tool. It is certain they were acquainted with the use of diamond powder.

The modern practice of cutting stones in intaglio is by an apparatus similar in principle to the turning lathe, which gives the cutting tool, placed horizontally, a quick rotatory motion; and the stone on which the design is to be engraved being brought in contact with it, the surface is ground away or indented, till the effect required is produced. Instruments of various sizes are used, which can easily be removed and replaced; and it is usual, during the process of engraving, to supply the points of the tools with diamond-dust mixed with a little sweet oil. As the work proceeds, proofs are occasionally taken in wax.

Engraving dies is an important branch of the art of intaglio, and requires great care and skill for its perfection. The die is made of finely prepared and tempered steel. When the first intaglio, or original die, is executed, it forms a *matrix* (or mould), into which a conically formed block of softer steel is compressed, the matrix first undergoing a process by which it is hardened. An impression taken in this way is called a *punchoon*. When this is completed (and frequent annealing and restriking are necessary before it is perfected), the engraver retouches the work, now in relief, and gives it all the delicacy of the original model; the metal is then hardened, and by pressing this punchoon into other steel which is soft (by almost a repetition indeed of the before-mentioned process), it serves for the purpose of making the dies for coining.

INTEGER, a whole number, as distinguished from a fraction.

INTEGRATION, INTEGRAL CALCULUS.

The integral calculus is the inverse of the **DIFFERENTIAL CALCULUS**; that is to say, if, A being given, it be a question of the differential calculus to find B; then, B being given, it is a question of the integral calculus to find A.

The question of finding a differential coefficient requires the attainment of the limit of the ratio of two simultaneously diminishing increments of y and x , y being a function of x : and therefore the fundamental principle of the integral calculus is as follows: Knowing the limit of the ratio of the increment of y to the increment of x , required the function of x which y is. Or, having given a function of x , required that function of which the given function is the differential coefficient.

But though this view of the fundamental question is sufficient in pure mathematics, it is not calculated to connect the process of integration with those conceptions which the mind employs in application to geometry or mechanics. We are here accustomed to a rough species of integral calculus, with which the preceding seems at first to have no connection. Thus a number of small straight lines joined together appear to compose a curve with sufficient exactness: we arrive at the calculation of a body's variable

motion by supposing it uniform during small intervals, and accelerated at the end of each interval: and we obtain the area of a curve with any degree of exactness by subdividing it into a large number of small curvilinear areas, for each of which we substitute a rectangle. It should seem, then, that when, making the proper use of the terms, we say that every magnitude is made up of an infinite number of infinitely small parts, we might add that every one of the parts is of a more simple kind than the whole. Thus we appear to have a right to say that a curve is made of infinitely small *straight lines*; that *gradual* variable motion is made up of infinitely small separate *impulses*; that the area of a curve is made up of infinitely small *rectangles*. A correct understanding of this connection is the key to that of the integral calculus, and most completely so to that of its ready application.

An integral is said to be definite when its limits are given: and indefinite when they are not given.

INTEGRATION, FINITE. By this term is meant the summation of any number of terms of a series which follows a regular law.

INTELLECT (*intellectus*), that which perceives and understands, comprehending all the cognitive powers of the mind, in contradistinction to the active powers of the will. In the Aristotelian philosophy the intellect first works on the phantasms, and discerns by a spontaneous energy what in many is one, what in things dissimilar is similar and the same. By this means it attains to a new kind of perceptions more comprehensive than those of sense; and each of these general ideas subsists entire in each individual of an infinite multitude without losing its own unity and permanence. On the other hand, it is the source of those primary principles on which all science rests, as conversant about universal and demonstrable truth.

For intellect Mr. Stewart prefers the vernacular term understanding, which he employs in the same extensive signification. But the critical philosophy of Kant distinguishes the intellect into two faculties, understanding and reason. The understanding acting on experience merely compares, judges, and measures its representations, and is conversant solely with their mutual limits and relations, classifying them according to certain schemes of its own which are called categories. While, however, the understanding is thus limited, the activity of the reason is unbounded, and, as the principle of principles, it is the base and the verification of every special principle and reasoning.

INTERCALARY DAY (Lat. *intercalo*, 'I insert'), in the calendar, a day inserted out of the usual order, to maintain the full sum of time. Thus every fourth year contains 366 days, or one more than usual, and the extra day is the intercalary day. It was given to February, as that was the shortest month, and thrust in by the Romans between the 24th and 25th days. It still retains that place in the ecclesiastical calendar, but in the civil calendar it is the 29th.

INTERCOSTAL (Lat. *inter*, 'between,' and *costa*, 'a rib'), in Anatomy, the appellation bestowed upon those bloodvessels, veins, and muscles, which lie between the ribs.

INTERDICT, ECCLESIASTICAL, a mode of censure employed at times by the Roman Catholic

Church, by which, in consequence of some offence alleged to have been committed by the people or rulers of a town or country, the Pope forbade by a bull the performance of any kind of church rites within the same; the church service was suspended, the sacraments were not administered, and the funeral service was not read. The use of interdicts appears to have originated with the bishops in the ninth century. In the middle ages this measure was often resorted to by the popes in consequence of some serious dispute with the sovereigns of particular countries, and it had the effect of throwing whole kingdoms into consternation, and even into a state of rebellion, by which the refractory sovereigns were obliged to sue for pardon from the pontiff.

In the course of time an interdict was found no longer to answer its object, so that it became of rare occurrence, and has for a long period been entirely disused as a general measure, although occasionally, in very special circumstances, and to mark the horror of the church for some enormous crime, instances are still recorded in which a particular place or church has been visited with the penalty of a local interdict.

The most remarkable interdicts were those laid upon Scotland in 1180 by Alexander III.; on Poland by Gregory VII., on the occasion of the murder of Stanislaus at the altar; by Innocent III., on France, under Philip Augustus, in 1200; and on England, under John, in 1209. The last instance was the ineffectual interdict levelled against Napoleon by Pope Pius VII. in 1809.

INTERDICT, in the law of Scotland, supplies the place of an injunction from a court of equity in England. It is a prohibitory order, forbidding some act from being done, and it is obtained on the application of the party who would be injured by the performance of the act. It may be issued by the Court of Session, or by the Sheriff's Court. Interdicts in the Court of Session are frequently obtained for preventing inferior courts, or the courts of limited operation, such as the ecclesiastical courts, from going beyond their jurisdiction.

INTEREST, money which is paid for the use of other money, the lender stipulating for a fixed sum to be paid yearly, half-yearly, or quarterly, for each 100*l.* lent, until the money is returned. When this is not the case, and when the money paid for the loan depends upon the success of an undertaking, or any casualty not connected with the duration of life, it is called a *dividend*: when the money and its interest are to be returned by yearly instalments, and paid off in a certain fixed number of years, it is called an *annuity certain*: but when the payment is to depend upon the life of any person or persons, it is called a *life annuity*.

INTEREST. (Law.) [USURY.]

INTERJECTIONS have been defined to be 'words used to express some passion or emotion of the mind,' as exclamations of joy, grief, astonishment, &c. Interjections, however, can hardly be considered as a distinct part of speech, but are more properly natural sounds common to all men when laughing, in pain, &c.

INTERLACKEN ('between the lakes'), a small town in the canton of Bern, Switzerland, between the lakes Brienz and Thun—whence its name. It is most beautifully situated on the left bank of the Aar, and has a population of 1364. It consists almost

entirely of boarding houses, as within a few miles are many of the most wonderful sights in Switzerland. The inhabitants carry on an enormous trade with visitors in beautiful wood carvings. The surrounding scenery is some of the finest in Switzerland, including the snow-capt peak of the Jungfrau, and the beautiful valley of Lauterbrunnen.

INTERLOCUTORY (*inter*, 'between,' and *loquor*, 'to speak'), a term applied to those judgments, decrees, and orders of courts of law and equity which are made in the progress of a suit before final judgment. Thus, orders for the production of papers, or for taking an account of the dealings out of which the dispute arises, are interlocutory orders or decrees. Those judgments which, though they establish the right of the plaintiff, leave the amount of damages to be ascertained by a jury, are generally, but incorrectly, called interlocutory judgments.

INTERLUDE, a brief piece of church music for the organ, seldom exceeding a few bars, generally produced *extempore*, and played between the verses of the hymn or psalm, or between different parts of a service. This, being merely for the purpose of giving breathing time to the singers, should always be short and grave, and in keeping with the psalm tune. On the stage, an interlude is a short entertainment introduced between longer pieces, or between the acts of a piece. The term *intermezzo* is sometimes employed in a similar sense.

INTERMARRIAGE. [CONSANGUINITY.]

INTERMENT. [FUNERAL.]

INTERMITTENT. [AGUE; FEVER.]

INTERNAL and EXTERNAL, geometrical terms applied to the angles made by the sides of a bounded figure. The angle made by two sides is an internal angle; that made by a side and a side produced, is an external angle.

INTERNATIONAL LAW. This term was originally applied by Bentham to what is generally called 'the law of nations.' The term 'law of peace and war' has been sometimes used as synonymous with 'the law of nations,' and as indicative of the boundaries of the subject. It was thus restricted to the disputes which governments might have with each other, and did not in general apply to questions between subjects of different states, arising out of the position of the states with regard to each other, or out of the divergences in the laws of the separate states. But under the more expressive designation, International Law, the whole of these subjects can be comprehended and examined, and thus several arbitrary distinctions and exclusions are saved. The following instances may be taken:—A port is put in a state of blockade; a vessel of war of a neutral power breaks the blockade: this is distinctly a question between nations, to be provided for by the law of peace and war, in as far as there are any consuetudinary rules on the subject, and the parties will submit to them. But suppose a merchant vessel belonging to a subject of a neutral power attempts an infringement of the blockade, and is seized—here there is no question between nations in the first place. The matter is adjudicated on in the country which has made the seizure, as absolutely as if it were a question of internal smuggling; and it will depend on the extent to which just rules guide the judicature of that country, and not on any

question settled between contending powers, whether any respect will be paid to what the party can plead in his own favour, on the ground of the comity of nations, or otherwise. But there is a third class of cases most intimately linked with these latter, but which are completely independent of any treaties, declarations of war, or other acts by nations towards each other. They arise entirely out of the laws of the respective nations of the world, in as far as they differ from each other. The 'conflict of laws' is a term very generally applied to this branch of international law, and the circumstances in which it comes into operation are when the judicial settlement of the question takes place in one country, but some of the circumstances, of which cognizance had to be taken, have occurred in some other country where the law applicable to the matter is different. One of the most common illustrations of this subject is—a judicial inquiry in England whether a marriage has taken place in Scotland according to the law of that country; or an inquiry in Scotland whether a marriage has taken place according to the law of England; in either of which cases there will generally be the further and nicer question, Which country's law ought to prevail as the criterion?

Thus the three leading departments of international law are:—

1. The principles that should regulate the conduct of states to each other.

2. The principles that should regulate the rights and obligations of private parties, arising out of the conduct of states to each other.

3. The principles that should regulate the rights and obligations of private parties, when they are affected by the several codes of different nations.

The first of these has been the principal subject of the works of Grotius, Puffendorf, Vattel, and other publicists, who have derived from general principles of morality and justice a series of rules for the conduct of nations towards each other, and subsidiarily for the conduct of their subjects in relation to international questions. It has been usual to call this department the 'Law of Nature,' as well as the Law of Nations, on the supposition that it is founded on the universal principles of justice.

The Law of Nations wants one essential element of that which is entitled to the term of law—a binding authority. Nations, even the most powerful, are not without checks in the fear of raising hostile combinations and otherwise; but there can be no uniformity in these checks; and in general, when the interest is of overwhelming importance, and the nation powerful, it takes its own way. The importance of the questions which may be involved in the Law of Nations thus materially affects the question how far it is uniformly obeyed. In minor questions, such as the safety of the persons of ambassadors, and their exemption from responsibility to the laws of the country to which they are accredited, and in other matters of personal etiquette, a set of uniform rules has been established by the practice of all the civilized world, which are rarely infringed. But in the more important questions, regarding what is a justifiable ground for declaring war? what territory a nation is entitled to the sovereignty of? what is a legitimate method of conducting a war once commenced? &c., the rules of

the publicists are often precise enough, but the practice of nations has been far from regular. The later writers on this subject have from this circumstance directed their attention more to the means by which any system of international law can be enforced, than to statements of what may be just, but has little chance of being enforced.

The second department into which we have considered international law divided—the rights and obligations of individuals as affected by the conduct of states towards each other—has, like the first, been examined by the publicists in their theoretical manner; but it has never, perhaps, received so much practical illustration as it did in the British courts, particularly the Prize Admiralty Court, during the late wars.

The third division of international law is that which most properly comes under the head 'Conflict of Laws,' the principles that should regulate the rights and obligations of private parties when they are affected by the codes of different nations. The leading rule of international law in this department is, that each civilized nation is to give efficacy to the laws of another country, unless its own laws or the general principles of justice are thereby contradicted. It has also been contended that when any neutral state has municipal laws for the regulation of its own subjects, with reference to their dealings with foreign countries at war with each other, either or both of such foreign countries in amity with such state may invoke the enforcement of such provisions of her municipal laws as restrict the subjects of such neutral state from committing any acts, the doing of which may be injurious to such foreign country. This principle appears to have been admitted during the late war between the Northern and Southern States of America, in the celebrated case, 'the Attorney-General v. Sillem and others,' touching the liability to forfeiture of the vessel *Alexandra*. The question there was, whether, by the municipal statute called 'the Foreign Equipment Act,' a British subject could be restrained from building or fitting out vessels of war for foreign belligerent states in amity with the queen? Although the finding of the jury, in accordance with the direction of the judge, was that the defendants had not been guilty of any infraction of the law, the duty of the Crown to prosecute offenders under that Act against friendly states was not questioned. But as the obvious policy of the 'Foreign Equipment Act' is to guard against this country being embroiled, by the acts of her own subjects, in foreign complications, it may still be a moot point whether a foreign country could claim its enforcement as a right. As regards the actual issue of the trial referred to, the ruling of the Lord Chief Baron (Pollock) was, in effect, that although it would be illegal for the British subject to build, fit out, or equip a vessel of war with intent to use it in hostilities against either of the belligerent states in amity with the queen, it would be perfectly lawful for him to build, fit out, and equip in this country, a vessel of war for sale to either of the belligerents, subject to its liability to capture and forfeiture as contraband of war, if intercepted by one belligerent in transit to the other. This dictum was the subject of several successive appeals upon one ground or other—from the

Court of Exchequer to the Exchequer Chamber, and ultimately to the House of Lords—but chiefly on collateral issues, which did not reverse or affect the ruling of the judge and verdict of the jury given in accordance therewith.

INTERNUNCIO, a papal envoy despatched to small states and republics, inferior to the nuncio, whose mission is confined to the courts of emperors and kings.

INTERPLEADER, or ENTER PLEADER, the name of a suit or action at law, or in equity. When a person who holds goods, or owes a debt or duty, is sued by two or more claimants, the court will order them to interplead upon the application of the party sued, and upon his delivering up or offering to deliver up the matter in dispute, and disclaiming all interest therein. The claimants then try their right to the thing demanded between themselves. [FEIGNED ISSUE.]

INTERPOLATION. Every mathematical table consists of a series of values of some algebraical expression corresponding to equidistant values of the letter on which it depends. Thus, the most extensive table of logarithms in common use is a succession of values of $\log. x$, answering to $x = 10,000$, $x = 10,001$, $x = 10,002$, and so on up to $x = 99,999$. The process of interpolation is that of inserting in a table values of the tabulated function intermediate to those given in the table. For example, suppose that p, q, r, s , &c., are written in a table opposite to $a, a + b, a + 2b, a + 3b$, &c., and it is demanded what is the value of the function corresponding to $a + 2\frac{1}{2}b$: this is a question of interpolation.

Such a question can only be solved approximately, but generally speaking, the values in the table are themselves but approximations, and the interpolated values are as correct as the tabular ones. A sufficient rule for most cases is, if a and $a + 1$ have A and B in the tables, differing by D , then to $a + m$, m being a fraction less than unity, belongs $A + mD$ or $A - mD$, according as B is greater or less than A .

INTERPRETATION. [HERMENEUTICS.]

INTERPRETATION. (Mathematics.) This word has come into use as descriptive of a process which it was long customary to employ, though without any express name. When an algebraical definition is laid down, there is frequently some restriction implied in the manner of making the definition, so that the process to which it leads presents more cases than can be explained by it, or were contemplated when it was made. For example, the abbreviation of a, aa, aaa , &c., into a, a^2, a^3 , and the rules which spring from it, soon lead to such results as—

$$a^{-3}, a^0, a^{\frac{1}{2}}, a^{-\frac{1}{2}};$$

which, though they follow from algebraical processes, yet, when they first arrive, are without algebraical meaning. In such a case, the process of interpretation enters. The question is, what should such symbols mean? have they a necessary meaning? if not, is there any meaning which will be more convenient than another? A definition has been laid down, leading to results which cannot be explained by it: required the extension of the definition which will enable it to explain its own results.

Examples are found in all works which explain

the principles of algebra. The rule always is, let the interpreted meaning of the new symbols be such as will make the whole of the process true by which they were obtained. Now, as they must have been obtained by the application of those formulæ which are true of the intelligible results of the definition, the rule just mentioned leads to the following: let the meaning of the intelligible results be such as will make the formulæ of the intelligible ones true of them. Thus, in the preceding instance, the fundamental formula which connects the terms of the series, a, a^2, a^3, a^4 , &c., is—

$$a^m \times a^n = a^{m+n}$$

which is intelligible when m and n are positive whole numbers. Suppose it now required to interpret a^0 , that is, to give it a meaning which shall make the preceding formula true of it. Write 0 instead of m , and we have $a^0 \times a^n = a^0 + n = a^n$, or a^0 must stand for 1. Again, suppose it required to interpret $a^{\frac{1}{2}}$. In order that the preceding formula may be true of the meaning of $a^{\frac{1}{2}}$, we must have

$$a^{\frac{1}{2}} \times a^{\frac{1}{2}} = a^{\frac{1}{2} + \frac{1}{2}} = a^1 \text{ or } a,$$

whence $a^{\frac{1}{2}}$ must stand for $\sqrt{a}$. And similarly for other cases.

INTERREGNUM, in an elective monarchy, the period between the death of one king and the election of another, or in a republic, between the expiration of the period of office of one ruler and the appointment of another. In a hereditary monarchy no interregnum can occur: *Le roi est mort; vive le roi* ('the king is dead; long live the king').

INTERVAL, in Music, is the difference or distance between two notes of different pitch.

Intervals are Simple when confined within the octave, *Compound* when they exceed it, and are named according to the distance of the two boundary notes. Thus the interval of a whole tone (C D) is called a 2nd; of a whole tone and a semitone (C E♭), a minor 3rd; of two whole tones, a major 3rd, &c.

INTESTACY is either the dying without a will, or with a will which does not dispose of the whole of the real or personal estate of the deceased; and therefore there may be either general or partial intestacy. Real estate, not disposed of by will, descends to the heir. [HEIR; DESCENT.] Personal estate, not disposed of by will, goes to the next of kin.

INTESTINA (*Intestinaux*), the second class of the *Radiata*, or fourth division of the animal kingdom, according to the classification of Cuvier. In the 'Règne Animal' this class is divided into two orders, *Cavitaria* and *Parenchymata*, which include all the *Entozoa* of Rudolphi; but the term Intestina, if retained at all, should be applied only to the true intestinal worms, or those parasites which live in the intestines of other animals, and should exclude the *Entozoa* which are found in the cellular tissue and substance of the different viscera of the body.

The principal species of worms infesting the stomach and intestines of man are enumerated under ANTHELMINTICS. For further details see ENTOZOA.

INTESTINES are that portion of the digestive canal into which the food is received after it has been partially digested in the stomach, and in which its further assimilation, the separation and absorp-

tion of the nutritive matter, and the removal of that which is excrementitious, take place. In an adult the intestines consist of a convoluted tube of from 30 to 40 feet in length, and are, from the difference of their diameters in different parts, divided into the *small intestines*, which comprise about the first four-fifths, and the *large intestines*, which constitute the other fifth of their length. The former again are divided into the *duodenum*, into which the ducts from the liver and pancreas open, and in which the chyme from the stomach is converted into chyle; the *jejunum*, in which the absorption of the nutritive matter of the food is principally effected; and the *ileum*. The large intestines are divided into the *cæcum*, *colon*, and *rectum*.

INTONATION, in vocal music, is the tuning of the voice—the singing true or false—in tune or out of tune. Correct intonation is the first requisite in a singer; this wanting, all his other musical qualities, however good, are unavailing. *Intoning* is the peculiar style of chanting or reading adopted in certain churches for particular portions of the liturgy.

INTRENCHMENT, in military matters, is a ditch or trench dug for temporary defence, with a parapet of earth thrown up for protection. When the ground is loose or sandy, fascines, gabions, or bags filled with earth or sand are employed to consolidate or strengthen the work.

INTROIT (Lat. *introitus*, 'entry'), in church ritual, the verses chanted or repeated when the congregation first enters the church; a custom as old as the fourth century, but not retained in the Protestant form of worship.

INULA, a genus of composite plants. *Inula Helenum* (Elecampane), one of the species of this genus, is an indigenous perennial herbaceous plant, found in moist meadows, the root of which is used in medicine. It is expectorant and stimulating, and is employed in debility of the stomach, but is not much used. It contains a white amylaceous matter called *inulin*.

INVALIDES, HOTEL DES. [PARIS.]

INVERARY. [ARGYLESHIRE.]

INVERCARGILL is the name of a town in South Island, New Zealand, the capital of the province of Southland. It is situated at the mouth of the New Ross river, five days' sail from Melbourne, and 156 miles by sea from Port Chalmers, in lat. 41° 15' S. Several newspapers are published here, and in the town are two banking establishments. In 1864 its port, Bluff Harbour, was opened, and a railway has since been constructed to it. The population of the town and suburbs was about 2000 according to the last return; and 235 ships, carrying 12,758 tons, entered the port in 1862.

INVERKEITHING. [FIFESHIRE.]

INVERNESS, a seaport town and royal burgh, the capital of the county of Inverness, and the principal town of the Highlands, is beautifully situated near the extremity of the Moray Frith, and the eastern entrance of the Caledonian Canal, 255 miles by railway N.W. from Edinburgh. The town is of considerable size and well built; the houses are lofty, and many of them elegant. The streets, since 1831, have been paved with granite and hard sandstone, brought from the banks of Loch Ness. Common

sewers have been constructed, and the town is well supplied with gas and water. Lat. $57^{\circ} 28' N.$, long. $4^{\circ} 13' W.$

The main streets are built on the eastern bank of the river Ness, which is traversed by a suspension bridge, replacing a stone bridge carried away in the floods of 1849, and by a wooden bridge at the north end of the town. The principal buildings are, three Established churches; ten chapels; county hall, and prison, on the site of the old castle; town-hall; a handsome spire, which once had connection with the lock-up; two newsrooms; a Working Men's Club; the head office of the Caledonian Bank; the usual public offices; royal endowed academy; infirmary; and reformatory. The climate is much milder than might be supposed from the northern position of the town, the mean annual temperature being about 46° . Inverness unites with Fortrose, Nairn, and Forres in returning one member to Parliament. The population of the entire district in 1861 was 20,380; the number of registered electors being about 900. The parliamentary borough of Inverness contained 12,509 inhabitants; the royal burgh, 9393; and the parish, 16,162. The parish measures 14 miles in length, by 2½ miles in breadth. There are extensive railway works, shipbuilding yards, iron foundries, rope works, two breweries; and manufactures of plaidings and woollen stuffs are carried on. The chief articles imported are coal, wine, grain, and tar; oats, timber, wool, sheep, and fish are exported. The port admits vessels of 400 tons to the harbour, and larger craft at Kessock Ferry and the Caledonian Canal. Its sub-ports are Cromarty, Burgh-head, Findhorn, Lossiemouth, Portmahomack, Fortrose, Fort George, Nairn, and from Sutherland to Fort William on the west coast. The number of vessels registered as belonging to the port in 1865 was 238 (11,615 tons). The entries in 1864—principally coastwise—were 2065 (167,348 tons), and the clearances 1837 (149,296 tons). The customs revenue in the year 1865 was 4851*l*. Regular traders ply to London, Leith, and Aberdeen; and by means of the Caledonian Canal to Glasgow, Liverpool, and Ireland. Inverness is the terminus of a system of railways which connect it with Sutherland, Ross, Perth, Edinburgh, and Aberdeen. Since the introduction of these lines, the town has been much visited by tourists, and greatly improved by the building of villas, and the erection of several handsome new streets. Its environs, well cultivated and beautifully wooded, are almost surrounded by mountains and hills of various heights, forming altogether a most picturesque and interesting landscape. The islands of the Ness, within a mile of the town, have been formed into a fine promenade, connected with the banks by elegant suspension bridges.

Though of great antiquity, the origin of Inverness is unknown; but a castle occupied an eminence to the south-east in the eleventh century, in which, according to tradition, King Duncan was murdered. English or Lowland Scotch is now the ordinary language of the inhabitants; but Gaelic is known to most of the working population, and to nearly all the servant girls belonging to the district, and is alone spoken in some of the secluded parts of the county. About 5 miles east of Inverness lies Cul-loden Moor, where the army of Prince Charles was

totally defeated in about half an hour in 1746, and became the victims of an unsparing slaughter.

INVERNESS-SHIRE, the largest county of Scotland, is bounded N. by Ross-shire, S. by the shires of Perth and Argyle, E. by those of Nairn, Elgin, Banff, and Aberdeen, and W. by the Atlantic Ocean. The mainland is comprised between $56^{\circ} 40'$ and $57^{\circ} 36'$ N. lat., and between $8^{\circ} 50'$ and $5^{\circ} 50'$ W. long. The greatest length from N.E. to S.W. is 85 miles, and the greatest width from N.W. to S.E. is nearly 55 miles. The entire county contains about 4600 square miles, or 2,944,000 acres. The population in 1861 was 88,888—47,524 females and 41,364 males—being a decrease of nearly 8000 on the census of 1851. There were 16,615 inhabited houses, 252 uninhabited, and 82 building. According to a parliamentary return issued in 1865, the number of electors then on the county register was 878, of whom 617 were tenants. Inverness sends one member to Parliament. It comprehends various districts, particularly those of Badenoch on the S.E., Lochaber on the S., Glenelg on the N.W., besides many inferior districts, such as Glengarry, Glen Morriston, Strathspey, Strathglass, &c. It also comprehends a considerable portion of the Hebrides, or Western Isles, including the Isles of Skye, Harris, Benbecula, North and South Uist, Barra, &c.

This county, which is extremely mountainous, is intersected by innumerable lakes and rivers, and is divided into two nearly equal parts by the deep valley usually called the Great Glen of Scotland, which runs from Fort William to Inverness. The county forms a large part of the Highlands of Scotland, and the Highland character and Gaelic language predominate in it. The low grounds are well cultivated; the lower hills are pastured by sheep, or reserved for grouse shooting, and the high grounds are for the most part set apart as deer forests, for which they are well adapted.

The prevailing rocks are of the primary class. Gneiss and mica slate are perhaps the most abundant, but huge masses of granite and of the oldest trap or porphyritic rocks are met with in the Grampians and the mountains of Glencoe and Ben Nevis. Limestone is found in several districts, and frequently approximates to the nature of marble. Sandstone is also met with in the southern sections of the country. The beds of the stratified rocks are usually highly inclined to the horizon, approaching almost to the vertical. Some veins of lead and silver have been discovered, and also iron ore in small quantities. The soil is for the most part light and sandy, with a subsoil of gravel or clay. The principal rivers are the Spey, Lochy, Ness, and Beaulie, in all of which there are valuable salmon-fisheries. The two principal mountains are Ben Nevis and Mealfourvounie. The former, which is separated from the Grampians by the desolate tract called the Moor of Rannoch, is composed of porphyry and granite; recent surveys have determined it to be the highest point in Great Britain, being 4406 feet above the level of the sea. It is easily ascended on the western side. Near its summit the snow lies for a great part of the year. Mealfourvounie rises 2730 feet above the sea-level. The surface of the county is an alternation of mountain ranges and deep shadowy glens. The principal ranges are the Grampians and the Monadhli,

the latter stretching from the borders of Lochaber to the neighbourhood of Nairn; its highest peaks attain an elevation of 2500 to 3000 feet, and in many parts the ridge forms an immense rugged mass, full thirty miles in breadth, presenting the utmost variety of outline and contrast of colour. The Ben-alder range, near Loch Erich, is less lofty but more picturesque; and the artist might well resort to its romantic recesses and abrupt pinnacles for inspiration.

All kinds of cereals and green crops are grown, but attention is chiefly directed to the rearing of sheep and cattle. The sheep are mostly of the black-faced and cross breeds; the cattle of the Skye or cross breeds. A great deal of waste land has been drained and reclaimed, and much ground planted. The fir woods in Glenmore and those of Strathspey, belonging to the earl of Seafield, are supposed to be more extensive than all the other natural woods in Scotland together. The native woods chiefly consist of oak, fir, birch, ash, mountain ash, elm, hazel, and the Scotch poplar. Those which are planted are the larch, spruce fir, silver fir, beech, plane, and fruit-trees. Red-deer, roe-deer, grouse, black-game, ptarmigan, woodcock, partridges, the alpine and common hare, and other game, are abundant.

Formerly a good deal of hemp, worsted, and linen yarn was made in this county; but this has greatly declined since the establishment of the large manufactories of the south. One considerable woollen factory (Mr. Nicol's) has long been in existence: another is in course of construction, and two others are in immediate contemplation.

The Glenmore, or Great Glen of Albion, as it is sometimes called, which stretches across the county from Fort William to the town of Inverness, is partially covered by three lakes, Loch Lochy, Loch Oich, and Loch Ness, lying nearly in a straight line between the above-mentioned limits. Their aggregate length is 37 miles, and the entire distance between Fort William and Inverness 60 miles. In 1802 Mr. Telford was appointed by the commissioners of the Treasury to make a survey of these lakes and of the adjoining country preparatory to the cutting of a canal. His report was made in the following year, and the works were in full operation in 1805, but the whole line of navigation was not opened till the latter end of the year 1822. It was repaired and re-opened in 1847. The expense of constructing the Caledonian Canal, as it is called, was defrayed by government, and amounted to 986,924*l*. That part of the navigation which is not upon the lakes is 22 miles and 1628 yards in length: it is 50 feet wide at the bottom, 110 feet at the surface, and 17 feet deep. Loch Oich is nearly the summit-level of the canal, and its elevation is 94 feet above the level of the sea on the east coast, at high water. The canal has not fully answered the expectations of its promoters; for instead of availing themselves of the route, seamen seem to prefer taking the chance of a favourable run round the northern extremity of Scotland. It is, however, extensively employed in summer for the transit of passengers and goods between the Clyde and Inverness; and forms an important link in the system of Highland tours inaugurated and still carried out by Messrs. Hutcheson, of Glasgow.

The scenery of Inverness-shire is exceedingly romantic and highly diversified.

The county contains thirty-six parishes, but no royal burgh, except Inverness, its capital. Fort William and Fort George, at opposite extremities of the Great Glen, were originally erected as strongholds to overawe the Highlanders. The former is a considerable garrison, capable of accommodating two or three thousand men. Fort Augustus, at the south-west extremity of Loch Ness, was built soon after the rebellion of 1715.

Portree, a fishing town on the east shore of the Isle of Skye, is the principal place on the west side of the county.

INVERSE, INVERSION. Any two operations of algebra are said to be inverse when one of them undoes, so to speak, the effect of the other; so that, if both be successively performed upon the same quantity, the result is that quantity itself. For instance, the operations implied in $1 + x^2$ and $\sqrt{x-1}$ are inverse to one another; for

$$1 + \left\{ \sqrt{x-1} \right\}^2 = x, \sqrt{1 + x^2 - 1} = x.$$

We need do no more than name addition and subtraction, multiplication and division, raising of powers and extraction of roots, as pairs of inverse operations.

INVERSION, in Music, is a change in the relative position of two sounds, or of the several notes of a chord. Thus C D, an interval of a 2nd, becomes by inversion (D C) a 7th.

INVERTEBRATE ANIMALS are those animals which do not possess a vertebral column or spine. All systems of zoology accept the natural division of animals into vertebrate and invertebrate. Cuvier divides the latter into Mollusca, Articulata, and Radiata, to which later zoologists have added Acrita and Protozoa.

INVERURY. [ABERDEENSHIRE.]

INVESTITURE. [FEUDAL SYSTEM.]

INVOLUTE AND EVOLUTE (the curve unrolled and the curve from which it is unrolled), a name given to two curves so formed and placed, that, supposing the second to be cut out from solid matter, the first can be formed by fastening one end of a thread upon a point in the second, attaching a pencil to the other end, and moving the pencil so that the thread may either gradually enwrap or be unwrapped from the curve to which it is fastened. Thus the pencil in the diagram is describing the involute of a circle, or the curve of which the circle is the evolute. But the evolute of a circle is evidently a point.

Every curve has one evolute, and an infinite number of involutes. The proper name for curves described from the same evolute is *parallel curves*, since they have the fundamental property of parallel lines: for they never meet, though (if they admit of it) ever so far produced; a straight line perpendicular to one is always perpendicular to the other; and the part of

the perpendicular intercepted is always of the same length. When arcs of parallel curves are required to be laid down, the most commodious method of proceeding is to construct the evolute of one of the arcs approximately, as follows. On the arc draw tangents at moderately small distances, and draw perpendiculars to those tangents. The parts of the tangents cut off from each by its neighbours will together give the arc of the evolute near enough for all purposes. And it may be well to notice that it will be a sufficiently accurate method of drawing the perpendicular to the tangent at a point P, if we take a small circle whose centre is P, bisect the arc A C B in C, and join and produce P C.

The angular error thus committed is only a small portion of the angle made by the tangents at P and A.

INVOLUTION AND EVOLUTION are algebraical terms—the former signifying the raising of powers, and the latter the extraction of roots. When any number is multiplied by itself, we get its square or second power; and if we multiply this product by the number again, we get the cube, or third power, and so on. The inverse process, called Evolution, enables us to find a particular root of a number—say, the fourth, or that number which, being multiplied into unity four times, the product will be the number originally given. Both subjects are treated of in every algebraical text-book.

INWOOD, the family name of three architects, father and two sons, who constructed many public and private buildings in London and elsewhere.

William Inwood was born about the year 1771. He was brought up to the professions of architect and surveyor. He was employed as steward to Lord Colchester, was surveyor to a large number of gentlemen, and several eminent architects were instructed by him. He died March 16, 1843.

Henry William Inwood, the eldest son of William Inwood, was born May 22, 1794. He was several years in Greece, and examined with great care the architectural remains at Athens and elsewhere. He

assisted his father in most of his architectural pursuits, especially in designing and constructing St. Pancras Church, New Road, London. He died March 20, 1843, when the ship in which he had sailed for Spain was wrecked, and all on board perished.

H. W. Inwood published in 1827 'The Erectheion at Athens, Fragments of Athenian Architecture, &c., illustrated with Thirty-nine Plates.'

IO (Gr. *ἰώ*), in ancient mythology, a daughter of Inachus, king of Argos, whose beauty excited the admiration of Zeus, and the jealousy of Hera. The queen of heaven, therefore, transformed her into a heifer, and intrusted her to the care of Argos Panoptes, who was slain by Hermes, thence called Argeiphontes, or the slayer of Argos. Hera then sent a gadfly who stung the heifer into madness, and drove her wandering over the earth; furnishing Æschylus with a subject for his tragedy of 'Prometheus Bound.' This legend seems to be connected with an old Egyptian myth.

IODINE (Gr. *iodēs*, 'violet-coloured'), a non-metallic elementary body, discovered by M. Courtois in 1812. Iodine exists in the water of the ocean and mineral springs, and in marine molluscous animals and sea-weeds; but it is principally obtained from *kelp*, or sea-weed which has been burnt for the purpose of obtaining alkali.

Iodine is a soft opaque solid, of a bluish black colour and metallic lustre. The primary form of the crystal is a right rhombic prisin, and the crystals are usually flat. According to Gay-Lussac, its specific gravity is 4.948. When moderately heated (at 345°) it rises in vapour of a violet colour, and hence its name, from the Greek *iodēs*. On cooling, it again crystallizes unchanged, nor is it decomposed or altered by being subjected to very high temperatures, and it has resisted all attempts to decompose it. Iodine has a strong disagreeable odour and taste; it stains the skin of a brownish colour, but not permanently; it is readily dissolved by alcohol, but scarcely at all by water. It is very poisonous. Its characteristic property is that of giving an intense blue colour when added to a solution of starch. It unites with metals to form compounds, which are termed *Iodides*, and, like chlorine and bromine, it forms acids both with hydrogen and oxygen.

Oxygen and Iodine combine to form three or four compounds. One of these, *Oxide of Iodine*, is said by Sementini to be a soft yellow substance, which by an addition of oxygen becomes *Iodous Acid*, a yellow liquid; but very little is known of these substances. *Iodic Acid* ($O^5 I$) is a white semitransparent solid substance, inodorous, but astringent. It is so dense as to sink in sulphuric acid, and it deliquesces in a moist atmosphere. It is very soluble in water; the solution reddens vegetable blue colours; it detonates when mixed and heated with charcoal, sugar, and sulphur. It combines with metallic oxides to form salts, which are termed *Iodates*. *Oxidic or Peroxidic Acid* ($O^7 I$) is a crystalline substance, easily resolvable by heat into its elements. *Nitrogen and Iodine* form *Iodide of Nitrogen*, which is a dark brown powder, very explosive: it consists of $N^1 I^3$. *Hydrogen and Iodine* form *Hydriodic Acid*, which has a sour taste, reddens vegetable blues, and when mixed with atmospheric air forms dense white fumes with its moisture. It is soluble in water. The salts

which it forms are termed *Hydriodates*. It consists of $H^1 I^1$. Chlorine and Iodine unite to form a *protochloride* (with chlorate of potassium); a *trichloride* (with chlorine gas); a *tetrachloride*, and a *pentachloride*. Sulphur and Iodine combine to form a *sulphuret*, which is a dark substance easily decomposed by heat. Phosphorus and Iodine combine to form three compounds: one ($P^1 I^1$) is an orange-coloured substance, which sublimates when heated; another ($P^2 I^2$) is a dark gray crystalline mass, which fuses at 84° ; a third ($P^2 I^3$) is a black substance, fusible at 114° .

The compounds of iodine and metals are mentioned under the names of the metals.

Medicinal Properties of Iodine.—Iodine, though only obtained in an isolated state of late years, has been long employed as the efficient principle of other preparations and therapeutic agents, namely, burnt sponge and certain mineral waters. It is only since it has been procured as a distinct principle that its action has been ascertained with precision. In the present day it is administered rather in some artificial compound than as pure iodine, owing to its very sparing solubility in water.

The diseases in which it has been found useful are glandular swellings, especially bronchocele or goitre, which rarely resists its action; in some strumous diseases; in chronic rheumatism; and also as an antidote in instances of poisoning with strychnia, brucia, and veratria; but its claims to confidence are not clear as to these formidable poisons.

IOLITE (Gr. *ion*, 'a violet,' and *lithos*, 'a stone'), a mineral of a dark violet colour, which, when viewed by a light transmitted at right angles, appears of a yellowish brown. It is found crystallized in six-sided prisms. Its specific gravity is 2.56; and its constituent elements, silica, 50.24; alumina, 33.42; magnesia, 10.84; oxide of iron, 4.00; water, 1.50.

IONA, also known by the names of Icolmkill and Hy, or I, is one of the Hebrides belonging to Argyleshire. It is situated on the western side of the Isle of Mull, from which it is separated by a narrow channel called the Sound of I. Its length is three miles, and at its widest part it is about one mile and a half in breadth. The general aspect of the island is rugged and mountainous, and the surface for the most part consists of moor and bog, occasionally varied by a patch of green pasture. It is one of the trap islands of the western coast, being composed chiefly of basaltic and trappean rocks, which frequently collect in grand columnar masses, and attain a considerable elevation.

The soil is naturally so very fertile that it was regarded as miraculous in the dark ages. Barley sown in the middle of June is ready for the sickle in August. The area is estimated at 2000 acres, of which about one-fourth is under cultivation. There is only one village, Baile Mòr, at which steamers from Oban call twice a week during the summer. A church and manse have been erected by government grant, and there is also a Free church and school. A small and comfortable inn, erected for the accommodation of tourists by the duke of Argyll, the present proprietor, was opened in 1864. The population of the island in 1861 was 264.

A religious establishment was founded on the

island by Columba, a native of Ireland, about the year 563. This was an establishment of Culdees, not subjected to vows, but governed by a code of laws formed by Columba; and it so continued for several centuries, with the highest reputation, not only for sanctity, but for learning. The remains of forty-eight Scottish kings, four Irish kings, and eight Norwegian kings, were interred there. For about 200 years it was a bishopric under the kings of Norway. When the papal power was established in Iona, the monastery became a Benedictine abbey. In 1507 the abbey of Iona was annexed to the diocese of the bishop of the Isles. In 1561 the whole of the ecclesiastical buildings were demolished. The revenues of the monastic institution were united to the see of Argyll, and upon the abolition of episcopacy they became the property of the duke of Argyll. This island is now chiefly interesting on account of its numerous architectural and other antiquities, a full account of which is given in Dr. Macculloch's 'Highlands and Western Isles of Scotland.'

IONE', or **JONE'**, a parasitic genus of minute crustaceans, placed by Desmarest under the *Isopoda*, but by Latreille under the *Amphipoda*.—Example, *Oniscus thoracicus*, Montagu, in 'Linn. Trans.,' ix. iii. 3, 4. This parasite hides itself under the shell of *Callianassa subterranea*, and there forms a tumour on one of its sides.

IONIA and **IONIANS**, a people belonging to the Greek or Hellenic race. Herodotus (viii. 44) says that the Athenians were Pelasgi, and that they took the name of Iónes from Ion, the son of Xuthus. The name only occurs once in the Iliad, and under the form Iáones. The Ionians at some unknown early period occupied the northern part of the Peloponnesus, along the Corinthian Gulf, and their country was called Ionia. When the Dorians invaded the Peloponnesus, about B.C. 1100, the Achæi [ACHÆI] took refuge in Ionia, which from that time was called Achæa, and the Ionians emigrated to Attica, but this emigration was probably gradual. From Attica there was a great emigration of Ionians and others under the sons of Codrus, the last king of Athens, which is called the great Ionian emigration; but there may have been various emigrations at different times. The Ionians established colonies in most of the Cyclades, such as Naxos, Andros, Paros, and Delos, and also in Eubœa. The emigrants who proceeded to the coast of Asia, under their leader Neleus, took Miletus, which was then inhabited by the Carians. They also took other towns on the same coast, which, with the islands of Chios and Samos, ultimately formed the confederation of the twelve cities of Ionia. Smyrna being seized by Colophonian exiles (according to Herodotus), was added to the confederation.

This confederation was united by a common religious worship and the celebration of a periodical festival. The place of assembly was the Panionium, at the foot of Mount Mýcale, where a temple, built on neutral ground, was dedicated to Poseidon. We have no materials for a history of these cities of Ionia as a political community, and no reason for supposing that their political union came near the modern notion of a federation.

Asiatic Ionia extended from the Cumæan Gulf on the north to Mount Grius and the Gulf Basilicis,

south of Miletus, a length of not more than 100 miles in a straight line, but with a coast three times that length, owing to the many sinuosities, and the form of the large Chersonesus opposite Chios. The Ionian territory did not extend inland above 40 miles from the coast as far as Mounts Sipylus and Tmolus. The principal rivers of Ionia were the Hermus, the Caystrus, and the Mæander.

The Asiatic Ionians early attained a high degree of commercial and maritime prosperity. Miletus alone is said to have founded seventy-five towns or colonies. They became wealthy and luxurious. The remains of their monuments prove their taste for the arts; and their temples and public buildings rivalled those of European Greece. The literature of Greece may be said to have originated on the coast of Asia Minor. The historian Hecateus was a native of Miletus; Thales, one of the earliest philosophers, was from the same country. Anacreon was a native of Teos; and Herodotus, though a Dorian, adopted, in his History, the language of his Ionian neighbours.

The subjection of the Ionians to the Lydian kings, their conquest by Cyrus, B.C. 546, and their subsequent struggle with the power of Persia, are the chief events in their history to B.C. 479, the date of the battle of Mycale. From that time their history is connected with that of Athens and Sparta, until the peace of Antalcidas, B.C. 387, by the terms of which the Asiatic cities were given up to Persia. Their subsequent history under Alexander and his successors can be very obscurely traced. Under the Roman empire several of the cities of Ionia still maintained the rank of wealthy cities, such as Smyrna and Ephesus. (Chandler's *Travels in Asia Minor*, and the *Ionian Antiquities*, published by the Dilettanti Society, 2 vols. folio; Colonel Leake's *Travels*; Dr. Smith's *Dictionary of Greek and Roman Geography*.)

IONIAN ISLANDS, the collective name given to the islands of Corfu, Cephalonia, Zante, Santa-Maura, Theaki, Paxo, Cerigo, and some small islets, all situated in the Ionian Sea, off the west coast of Albania and the coast of Greece. The area and population of the seven principal and only inhabited islands are as follows:—

	Area in sq. miles.	Population in 1862.
Corfu, ...	275	75,532
Cephalonia, ...	256	70,541
Cerigo, &c., ...	107	13,007
Leucadia, ...	110	20,043
Paxo, ...	7	5,025
Ithaca, ...	37	11,348
Zante, ...	164	38,627
Total, ...	956	234,123

The islands rise in irregular rugged abruptness from the sea, and their structure consists chiefly of limestone, gypsum, and sandstone. Oil, wine, corn, some cotton, the small species of grape called currants, and other fruits, and flax, are the chief productions; the olive is extensively cultivated in all the islands; the currant is grown in the greatest perfection in Cephalonia and Zante. Earthenware, salt, soap, and some coarse woven goods, are the

principal industrial products. The fisheries give employment to a considerable number of hands. The coasting trade is important. The imports consist of sugar, coffee, and drugs; raw and manufactured cotton and silk; wool and woollen cloth, glass, hardware, staves and hoops; iron, timber, wheat, Indian corn, rice, cheese, flour, fish, cattle, sheep, tobacco, &c. The import and export trade is almost entirely carried on in British ships. The productions of the Ionian Islands in 1860 comprised 69,553 barrels of olive oil, worth from 50s. to 55s. a barrel; 30,250,897 lbs. of currants, worth from five to ten guineas per 1000 lbs.; and 148,539 barrels of wine, ranging from 11s. to 21s. a barrel. Only 67,580 bushels of wheat were grown in the year. The soil is more favourable to grape cultivation than to the raising of corn, and corn and flour are the chief imports. The live stock consisted of 13,171 horses, 10,374 horned cattle, 131,684 sheep, and 111,907 goats, showing a considerable increase within a few years. The revenue of 1860 was 140,855*l.*, the expenditure 151,187*l.*; in the preceding twelve years the Ionian revenue had only on two occasions provided the exchequer with a surplus. The export duty on oil produced above 80,000*l.* in 1857, only 19,000*l.* in 1859, and 27,000*l.* in 1860. More than a third of the revenue in the year 1860 was raised from the export duties of 19½ per cent. on olive oil and currants. The total value of the goods exported from the Ionian Islands to Great Britain—chiefly currants and olive oil—in 1864 was 189,259*l.* The exports from this country were valued at 454,599*l.* Cotton and woollen goods were the staple commodities.

Shipbuilding is an important branch of industry, and many of the inhabitants are engaged in maritime trade and navigation.

The climate of the Ionian islands is mild and healthy; the winters are rainy, and attended by boisterous winds; the heat in summer is moderated by the north-east wind; it is only when the sirocco blows that any inconvenience is experienced from the heat. Shocks of earthquake are often felt in winter, especially in Zante.

There is a university and an ecclesiastical college for clergy of the Greek Church at Corfu; and each of the islands and chief towns has a school, in which ancient Greek and Latin, modern languages, and mathematics are taught. Besides these educational establishments there are numerous district schools.

About four-fifths of the whole population are of the Greek Church, which is the established religion, and are under the spiritual government of an exarch or primate, which office is held for five years in rotation by the Greek archbishops of Corfu, Cephalonia, and Santa-Maura; each island has besides its own archbishop or bishop. The rest of the population, with the exception of some of the British residents, and about 5000 Jews, are Catholics, who are superintended by one archbishop and two bishops. The language of the islands is modern Greek. The inhabitants are of Greek and Albanian descent, with a considerable admixture of Italian blood.

Cephalonia and *Corfu* have been noticed under separate heads.

Cerigo, the ancient *Cythera*, the fabled birth-place and resort of the goddess Venus, presents a rocky and barren aspect. It is the most southern of the

islands, lying E. of Cape Matapan, and is traversed nearly through its centre by the meridian 23° E. long. The chief products are corn, wine, oil, raisins, honey, and wax; some cotton and flax are also grown; a great number of goats are fed. More cattle are reared here than in any other of the Ionian islands. Some remains are shown, near the chief town, Capsali (population 5000), which are stated to have formed part of the temple of Venus, mentioned by Pausanias. The olive oil and honey produced in this island are much esteemed.

Santa-Maura, the *Leucas* of the ancient, and the *Leucadia* of the modern Greeks, lies nearly opposite the entrance of the Gulf of Arta, and is twenty miles long by from six to ten wide. It is separated from the mainland by a long narrow channel navigable only for canoes (monoxyla), and consists of a range of mountains, terminating northwards in a flat peninsula, and southwards in the Leucadian promontory or Cape Ducato, about two miles N. by W. of which is the rock called Sappho's Leap, whence the lovelorn poetess is said to have plunged into the sea from a height of 200 feet. The east side of the island is barren; the north and west parts consist of a rich soil, and are very productive. The olive, the vine, and other fruit trees, are the principal objects of cultivation; corn is produced, but not in quantity nearly enough for the consumption; the fisheries and the manufacture of salt are a great source of employment to the inhabitants, many of whom emigrate to the mainland in harvest time to work. The chief town of the island, *Amazichi*, or *Santa-Maura*, is unhealthily situated on the low peninsula in the north of the island; it is much resorted to for the purchase of manufactured goods, which are supplied chiefly from Malta. Population 7000. On an islet N. of the town stands the castle of Santa-Maura, which is joined to it by a causeway, constructed on 365 arches, over the salt lagoon that separates the island from the main. In the mountains, the highest of which is St. Elias (3000 feet above the sea), game is abundant, and the lagunes swarm with pelicans and almost every species of water-fowl. The antiquities are the tomb of Artemisia and the ruins of the town of Leucas.

Paxo lies ten miles S. of Corfu; it is only about five miles long, and scarcely two broad; the surface is rocky, mountainous, arid, and deficient in water. The principal produce is oil, which is of excellent quality. The chief place is *Porto-Gayo*, a mere cluster of houses built on the shore.

Theaki, or *Ithaca*, lies E. of Cephalonia, from which it is separated by a long narrow strait. It is fourteen miles long and four broad at its widest part; but it is deeply indented about the middle of its length on the eastern side by the beautiful Bay of Vathi, between which and the channel of Cephalonia is a narrow isthmus that unites the northern and southern parts of the island. The limestone range which runs through its whole length, rises everywhere into rugged eminences, so that the surface of the island is entirely destitute of plains and valleys properly so called, there being scarcely one hundred yards of continuous level ground in the island. The soil is light and shallow; yet olives, currants, fruits, superior wine, and some corn, are raised by the industrious population. The honey of

Ithaca is greatly valued. The climate is renowned for its salubrity; the inhabitants commonly reach 80, 90, and not unfrequently 100 years of age. *Vathi*, the chief town, stands on the shore of the little bay of Dexia, an inlet from the Bay of Vathi, and has 2500 inhabitants. The chief antiquities of the island are the cyclopean walls, named the castle of Ulysses, which stand on Mount Aito, in the isthmus before mentioned. The rocky surface of the island presents numerous caverns, to which the shepherds and their flocks retire by night.

Zante, the *Zakynthos* of the ancient and modern Greeks, situated about eight miles S. of Cephalonia, and fifteen W. of the Morea, is a beautiful and fertile island. It is about twenty-three miles long, and consists chiefly of an extensive plain that stretches from the north to the south coast, with a breadth of six to eleven miles, and terminates westward in a range of hills running parallel to the coast, and eastward in Mount Skopo and the hills about the city of Zante. The products are similar to those of the other islands, but more abundant. Pomegranates, peaches, melons, and citrons, are cultivated, and some salt is manufactured. The wine of Zante is of superior quality, and in great request all over the Levant. The great trade of the island is in *currants*, the fruit of a dwarf vine originally brought from Corinth, whence the name. The *Petroleum* or *Pitch Wells*, described by Herodotus (iv. 195) are about twelve miles S. from the town of Zante, in a marshy district, near the shore of Chieri Bay, in the south-eastern part of the Island. Another well, called the *Tallow Well*, is in a cavern on the shore. There are very few remains of antiquity in the island. *Zante*, the largest, most populous, and most commercial town of the Ionian Islands, stands at the head of a bay on the east coast. The population is 20,000. The streets are narrow, as in all warm climates; the houses are well built, chiefly in the Italian or Venetian style. The churches are numerous, and richly ornamented. There are two piazzas or squares, in one of which is erected a handsome monument to Sir Thomas Maitland. The harbour is protected by a wall, and has a lighthouse; but it is much less secure than those of Theaki and Cephalonia. From the citadel, which stands on the highest part of the town, there is a magnificent view over Cephalonia, the gulf of Lepanto, and the coast of the Peloponnesus. Zante is the seat of a Greek archbishop and a Catholic bishop; it has a theatre, a custom-house, and an arsenal. The city has frequently suffered from earthquakes; those of December 29, 1820, and January 19, 1825, were very destructive.

The smaller dependent islands are *Merlera* and *Fano*, which lie N.W. of Corfu; *Anti-Paxo*, S.E. of Paxo; *Kalamo* and *Meganisi*, E. of Santa-Maura; and *Cerigotto*, which lies S.E. of Cerigo, and is the most southern, as well as the most eastern, of the Archipelago.

The Ionian islands were subject to Venice from 1386 to 1797, when they were ceded to France. They were seized by Russia and Turkey in 1800, by France in 1807, by Great Britain in 1809, and on November 5th, 1815, were formed into a republic ('the Septinsular Republic') under the protectorate of the latter, and so remained till October, 1863, when the Parliament at Corfu unanimously voted

their annexation to the kingdom of Greece, which was accomplished, with the consent of the British government, in 1864. [GREECE, CORFU.]

IONIAN SCHOOL comprises several of the earliest philosophers of Greece, whose speculations were chiefly of a physical character, and who, with one or two exceptions, were natives of the Ionian colonies in Asia Minor.

IONIC DIALECT, one of the four written varieties of the Greek language, was spoken in the Ionian colonies of Asia Minor, and in several of the islands of the Egean Sea. As the new Ionic, it is distinguished from an older, which was the common origin of itself and the Attic. The old Ionic was widely diffused, and its use was co-extensive with the Ionian settlements in the Peloponnesus and Northern Greece. The language of epic poetry arose out of this original tongue, which after the Dorian conquest passed, on the one hand, with the fugitives into Asia Minor, while on the other, it continued to be spoken, for a while at least, by the conquered peasantry who remained in Greece Proper. Herodotus (i. 142) distinguishes four varieties of the new Ionic, in one of which he wrote, and though a Dorian, has left us the best and most complete specimen of it. Hippocrates and Galen also wrote in this dialect.

IONIC ORDER. [CIVIL ARCHITECTURE.]

IONI'DIUM, a genus of violaceous plants inhabiting the tropical parts of America. Several species are used medicinally. *I. Ipecacuanha* and some others have emetic roots. [IPECACUANHA.]

I O U. A mere acknowledgment of a debt which does not amount to a promissory note.

Such an acknowledgment is frequently made in an abbreviated form, thus:—

London, 1st January, 1866.

To Mr. A. B.

I O U one hundred pounds. C. D.

An acknowledgment in this form is called an I O U, and is evidence that at the time when it was made, there was a debt due to the party to whom it was given for the amount specified.

Being merely evidence of the existence of debt, it requires no stamp. It is neither a promissory note nor a receipt, but, except that it cannot be negotiated and circulated, it has all the effect of a promissory note payable on demand; for a debt is acknowledged to be due, and may be sued for at any time.

It is always desirable to adhere strictly to the above form, for if words be added expressing a promise to pay the amount on a particular day, the instrument would then be a promissory note, and could not be given in evidence without a stamp. Again, the addition of certain other words might make the document amount to an *agreement*, in which case, if over 20*l.*, it would require a stamp. In this case, however, there is less danger, for an agreement may be stamped after it is written, or even at the trial, on payment of a fine, but a promissory note cannot.

If the name of the person to whom it is given does not appear on the I O U, it will, *prima facie*, be taken as evidence of a debt due to the person who produces it; but this the defendant may, of

course, rebut. To avoid difficulties, the creditor's name should always be mentioned, as in the form given above.

IOWA, one of the United States of North America, had its boundaries defined by an Act of Congress passed August 4, 1846. It is situated between 40° 20' and 43° 30' N. lat., and 90° 12' and 96° 53' W. long., the area being 55,045 square miles. It is bounded N. by Minnesota; E. by Wisconsin and Illinois, from which it is separated by the Mississippi river; S. by Missouri; and W. by the Nebraska Territory, from which it is separated by the Missouri river. The population in 1840 was 43,112; in 1850, 192,214; in 1860, 674,948.

The surface is undulating and beautiful, with alternate forests and prairies. There are no mountains, but bold bluffs, with picturesque ravines, line the rivers, which, rising in the elevated grounds of the northern parts of the territory, flow respectively eastward into the Mississippi, westward and southward into the Missouri, and northward into the British possessions. James River has a course S. of upwards of 400 miles, and falls into the Missouri. Of the rivers which fall into the Mississippi, one of the largest is the Des Moines River, which is navigable for 300 miles from its mouth. Next in size is the St. Peter's River, with its numerous tributaries, which flows about 300 miles S.E., then about 200 miles N.E., and falls into the Mississippi a little below the Falls of St. Anthony. The Skunk River, the Lower Iowa, with its affluent the Cedar River, the Wabepisipimecon River, the Great Macquonetois River, the Turkey River, and the Upper Iowa are also rivers of large size. Of the rivers which flow northward the Red River is the largest; it has a course of from 300 to 400 miles northward before it enters the British possessions, through which it flows to Lake Winnipeg. In the most northern and north-eastern part of the state the country is flat and swampy, and there are numerous lakes.

The soil is exceedingly fertile, and the climate generally healthy. Maize, wheat, barley, potatoes, fruits, wool, tobacco, and furs are the chief products; and lead, copper, zinc, and iron ore are abundant. Portions of the state are occupied by the Ottawa, Chippeway, and several other Indian tribes.

Iowa was separated from Wisconsin in 1838. In 1855 *Fort Des Moines* was made the capital. The state is now being rapidly covered with railways. It is divided into forty-nine counties, and returns two members to Congress. Besides the capital, the chief towns are Iowa, Burlington, and Dubuque.

Iowa, on the river of the same name, has 5214 inhabitants, and a capitol of Grecian-Doric architecture, now used as the state university. It was formerly the capital of the territorial government, and is built on a succession of plateaux rising from the river. It has some state asylums and several factories on the falls of the river.

Burlington, on the Mississippi, 250 miles above St. Louis, has a population of 6706, with a court-house, several churches, and a gaol.

Dubuque is on the right bank of the Mississippi, 70 miles N.E. of Iowa city. It is the emporium of the lead mines of this and the states of Wisconsin and Illinois. Many railways meet here. In 1860 the inhabitants numbered 13,000.

The legislature of Iowa consists of forty-six senators and ninety-three representatives. The senators are elected for four years, and the representatives for two years.

IPECACUANHA (Peruvian, *ipe*, 'a root,' and *cacuan*, the name of this particular plant) is an emetic substance, the root of several plants growing in South America. All the kinds have nearly the same ingredients, but differ in the amount of the active principle which they respectively contain, termed emeta. The best is the annulated, yielded by the *Cephaelis Ipecacuanha*, a small shrubby plant, native of Brazil and of New Granada. Of this sort there are three varieties, namely, the brown, red, and gray, or gray-white, called also greater annulated ipecacuan. As this is the only sort sent from Rio Janeiro, it is sometimes called Brazilian or Lisbon ipecacuanha. It is sent in bales and barrels.

The dust or powder of ipecacuanha applied to any mucous surface causes irritation and increased secretion from the part. It is chiefly employed to excite the stomach either to augmented secretion, or to invert its action, and effect vomiting. It is also capable, by being combined with other substances, of being directed to the skin, and producing increased perspiration. From 15 to 20 grains of the powdered root in an ounce of water is an emetic; one to four grains, a nauseant; and a fourth of a grain to a grain, an expectorant and diaphoretic.

The imports of ipecacuanha into the United Kingdom in 1864 amounted to 59,078 lbs., value 23,359*l*.; and the exports to 45,891 lbs., value 18,165*l*.

IPHICRATES, an Athenian general, who introduced a happy innovation upon the ancient routine of Greek tactics, during that general war which was ended B.C. 387 by the peace of Antalcidas. Iphicrates laid aside the weighty panoply which the regular infantry, composed of Greek citizens, had always worn, and substituted a light target for the large buckler, and a quilted jacket for the coat of mail; at the same time he doubled the length of the sword, usually worn thick and short, and increased in the same, or by some accounts in a greater proportion, the length of the spear. It appears that the men also carried missile javelins, and that their mode of attack was to venture within throw of the heavy column, the weight of whose charge they could not have resisted, trusting in their individual agility to baffle pursuit. When once the close order of the column was broken, its individual soldiers were overmatched by the longer weapons and unnumbered movements of the lighter infantry. In this way Iphicrates and his targeteers (*peltastæ*) gained so many successes, that the Peloponnesian infantry dared not encounter them, except the Lacedæmonians, who said that their allies feared the targeteers as children fear hobgoblins. They were themselves taught the value of this new force, B.C. 392, when Iphicrates waylaid and cut off nearly the whole of a Lacedæmonian battalion. Iphicrates afterwards commanded in the Hellespont, B.C. 389; in Egypt, at the request of the Persians, B.C. 374; relieved Corcyra in 373, and served with credit on other important occasions.

IPOMEA (Gr. *ipa*, 'a worm,' and *homoios*, 'like'), a genus of plants of the natural family of *Convolvulaceæ*, which is very closely allied to

Convolvulus, or Bindweed. The species are very numerous, and found in the tropical parts of Asia, Africa, and America. A few ascend the mountains in such latitudes.

Like the kindred genus *Convolvulus*, which affords us scammony, many of the species of *Ipomœa* are useful for their purgative properties; thus the Jalap plant is of this genus. [*CONVOLVULUS JALAPA*.]

I. Jalapa is a species which has not long been accurately determined, though its root has so long and so extensively been employed as a powerful medicinal agent.

IPS (Gr. *ips*, a wood-piercing insect, so called from *ipto*, 'to destroy'), a genus of coleopterous insects, of the family *Silphidæ*, generally found under the bark of trees.

IPSAMBUL. [*ABOUSAMBUL.*]

IPSWICH. [*SUFFOLK.*]

IRAK ARABI. [*BAGDAD.*]

IRAWADDY. [*BERMA.*]

IRELAND, an island on the N.W. of Europe, forming part of the United Kingdom of Great Britain and Ireland, extends from 51° 26' to 55° 21' N. lat., and 5° 20' to 10° 26' W. long. It is surrounded by the Atlantic on all sides, except the E., where it is separated from Great Britain by St. George's Channel, 47 miles across where narrowest; the Irish Sea, 138 miles; and the Northern Channel, 13 miles. Its shape is that of a rhomboid, the greatest diagonal of which is 302 miles, and the lesser, 210 miles; the greatest length on a meridional line is 225 miles; the greatest and least breadths on parallels of latitude, 174 and 111 miles; comprising an area of 32,509 square miles, or 20,808,271 acres.

Coasts.—The northern, western, and southern coasts are indented with numerous deep and safe bays; the eastern side presents but few suited for large vessels. Their total number has been estimated at fourteen capable of harbouring the largest men-of-war; fourteen for frigates; from thirty to forty for coasting vessels; and twenty-five good summer roadsteads; besides numerous inlets for fishing craft. There are in operation more than sixty coast light-houses, and three floating lights, which are maintained in an efficient state at an expenditure of about 60,000*l*. a year.

The Islands are numerous but small. The total number is 196: the largest are Rathlin and Tory, N.; Achill, Clare, the South Arran Isles, and Valentia, W.; and Whiddy and Cape Clear, S.

Surface.—The greater part of the surface is a plain, not strictly level, but mostly interspersed with low hills. The principal mountain groups are, N.E., the Mourne mountains in Down county—highest, Slieve Donard, 2796 feet above high sea-level; W., the mountains surrounding Clew Bay in Mayo county—highest, Mulrea, 2688 feet; S.W., M'Gillicuddy's Reeks in Kerry county—highest, Carran-Tual, 3414; E., the Wicklow mountains—highest, Lugnaquilla, 3039 feet. The interior of the country is intersected by several lofty ranges, among which the Devil's Bit, Slieve-Bloom, Galtees, Mount Leinster, and Blackstairs, are the most remarkable.

The Rivers are numerous: the principal is the Shannon, 159 miles long, from Lough Allen to Limerick, where it expands into an estuary of 45 miles, opening into the Atlantic; it is navigable through

nearly the whole of its course. The Suir, Barrow, Nore, Blackwater, Slaney, Boyne, Foyle, Erne, Lee, Bandon, Bann, and Moy, are all navigable to a greater or less extent: smaller rivers, serving chiefly for agricultural and domestic purposes, are to be met with in every district.

The Lakes, generally termed loughs, are numerous: the largest, Lough Neagh, in Ulster, covers 98,255 acres; the others more remarkable are, Loughs Erne, Corrib, Mask, Conn, and the Lakes of Killarney. Altogether the lakes in Ireland occupy a surface amounting to nearly 1000 square miles.

Climate.—The climate is temperate and moist. The number of days on which rain fell, as registered at the Ordnance Survey Office, Phoenix Park, was in 1855, 189, in 1860, 210, and in 1863, 212 days. The crops are more frequently injured by excess of moisture than of aridity. Plants which require artificial heat in England, flourish here in the open air; while, owing to the humidity of the atmosphere, many kinds of seeds must be supplied from England or the Continent. This peculiarity of climate is not prejudicial to health; the average of life is much the same as in Great Britain; longevity much greater. The prevalent diseases are low fever and consumption. The mean temperature in the N. is 48° Fahrenheit; in the middle, 50°; and in the S., 52°.

Geology.—The geological structure of Ireland has this striking peculiarity, that most of the great mountain ranges are near the coast, while the central portion is an almost uniform plain, varied only by low hills. The prevailing formations are limestone, granite, mica-slate, clay-slate, old red sandstone, yellow sandstone, and basalt or trap. The limestone extends over the central plain, 120 miles E. and W., from Dublin to Galway Bay, and 120 miles N. and S. Its greatest elevation is about 300 feet, which is the height of the summit levels of the canals that traverse it. The principal tracts of granite are those of Wicklow, Galway, Newry, and Donegal. The mica-slate of Leinster is confined to a narrow fringe, edging the granitic region of the province; in Donegal and Galway it spreads over large tracts. The clay-slate is among the most important rocks, both for extent of area and valuable mineral deposits. The counties of Wexford, Louth, Waterford, Cork, and Kerry, are mostly formed of it. In the north it is contained in the district bounded by a line from Longford to Drogheda, eastward, and to Donaghadee, north-eastward. At Kingscourt, Carrickmacross, and Cavan, the clay-slate dips and forms a basin, in which the limestone and coal formations are deposited. Slate is quarried extensively at Killaloe and Westport, in Clare, and in Wicklow. The old red sandstone is chiefly developed in the south; it forms the greater part of Cork and Waterford counties, and of the inland mountain ranges of Knockmeledon, Comme-ragh, and the Galtees; it shows itself also in several places in Westmeath, Longford, and Leitrim. A large tract of old red and yellow sandstone forms the sea-coast at Killaloe, skirts Loughs Conn and Cullen, and reaches the Atlantic at Westport. An extensive tract in Fermanagh and Tyrone, from Lough Erne to Cookstown, has this rock for its basis. It is also found in patches in Antrim, Derry, and Tyrone. Crystallized gypsum occurs in Derry and Antrim, and selenite at Benburb. Uncrystallized gypsum is raised in

large quantities at Carrickmacross. The yellow sandstone usually accompanies the red, and rests upon it. The basalt or trap occupies a very limited area, being confined almost exclusively to the N.E. portion of the island, forming the substrata of the county of Antrim and of some portions of Derry and Armagh.

Mines, &c.—The principal minerals are coal, iron, copper, lead, and gold. The coal-fields are seven in number: one in Leinster, occupying large portions of Kilkenny and Queen's counties, with a small part of Carlow; two in Munster, one in Tipperary, bordering on that of Kilkenny, the other spread over large portions of Clare, Limerick, Cork, and Kerry counties, being the most extensive development of the coal strata in the British empire. All these beds lie S. of Dublin, and yield only stone coal, or anthracite, which burns without flame. The remaining fields, which lie to the N. of Dublin, are formed of bituminous or flaming coal. Of the northern coal-fields, three are in Ulster—one at Coal Island, near Dungannon, the second in the northern extremity of Antrim county, and the third in Monaghan. They are all small—the narrowness of the seams of coal rendering the last-named almost valueless. The Connaught coal-field extends over portions of Roscommon, Sligo, Leitrim, and Cavan counties. The total quantity of coal raised in Ireland in 1864 was 70,000 tons of anthracite and small coal, and 55,000 tons of bituminous coal. The number of collieries in Ireland is seventy-three, chiefly situated in Kilkenny, Tipperary, and the Queen's County. Only thirty-nine of these are working. Besides the stores of fuel applicable to manufacturing and domestic uses which lie imbedded in the coal-fields, Ireland enjoys two others—lignite, and turf or peat. Lignite, an intermediate species of fuel between wood and coal, is found in dense strata encompassing the southern half of Lough Neagh. The total area of turf bog is estimated at 2,830,000 acres, nearly one-seventh of the surface of the island. Of this quantity, 1,576,000 acres are flat bog, spread over the central portions of the great limestone plain; the remaining 1,254,000 are mountain bog, chiefly scattered over the hilly districts near the coast.

The tracts of peat bog which cover the limestone plain of Ireland seem to be formations occasioned by inequalities of surface. The natural course of streams from springs and rain-falls having been obstructed, stagnant lakes and pools were formed, which promoted the growth of aquatic reeds, grasses, and rushes; and these, by their constant increase and decay, appear to have composed the mass of the bogs in Ireland. The average depth of these bogs is commonly from 16 to 25 feet, but some reach from 30 to 35 feet; and the extreme depth observed is 47 feet.

That fallen forests were not the origin of these peat bogs seems evident from the circumstance, that two and even three successive growths of trees have been observed at different depths in a section of the same bog. In these instances the trees lay horizontally, frequently crossing each other, either attached to their roots or broken over; and in the latter case the stumps usually stood erect. The prostration of trees may, however, to a certain extent, have been an auxiliary in promoting the growth of peat; and

this prostration appears to have taken place either from natural decay, or from trees which possessed little hold of a wet spongy soil having been overturned by storms. This may partly account for trees of all ages being found in the bogs of Ireland, whether these bogs be in plains, or form the immediate cover of high mountain tracts. That Ireland was once covered by extensive forests, even in the more elevated chains, can scarcely be doubted; for numerous stools of trunks, long since cut down, yet remain in most of the mountain districts. The destruction of the forests of Ireland is to be attributed principally to the general introduction of iron furnaces; and the almost total neglect of copping the tracts in which the woods had been felled. The bogs of Ireland have no analogy to the fens of England, as they lie in all cases so far above the sea level as to be readily susceptible of drainage and reclamation. Notwithstanding their moisture they are not insubrious, owing to the large quantity of tannin which they contain; and such are their antiseptic properties, that bodies of men and animals have been found in them with but few symptoms of decay, after the lapse of generations.

Iron ore is found in all the localities of coal, and was largely manufactured while timber for fuel was abundant, but there are now only a few mines working. The total yield of ore in 1864 was 60,602 tons, value 20,326.

In 1864 the mines of Wicklow produced 66,894 tons of iron pyrites, valued at 37,320*l.*; and from the Belfast district considerable quantities of black band ironstone are now shipped to Scotland.

The copper mines are distributed throughout the clay-slate districts in a great number of localities. The quantity of Irish copper ore sold at Swansea in 1864 was 14,237 tons, valued at 122,000*l.*

Lead is more extensively diffused through Ireland than copper. The granitic district of Wicklow contains numerous veins. The clay-slate districts also yield numerous indications of this metal, but few of the mines have proved profitable. The quantity of lead raised in 1864 was 441 tons, containing 15,534 ounces of silver.

The value of silver produced from ores raised in Ireland during the years 1859-64 was 22,467*l.*, at 5*s.* 6*d.* per ounce.

Tin stone has been found in the auriferous soil of Wicklow, but no veins or working deposits have been discovered. Zinc was obtained at the Silver Mines in Tipperary in 1860.

Other minerals, useful in manufactures and the arts, and found in quantities in various parts of the country, are manganese, antimony, nickel, tin, alum, clays of various kinds, building stone, marble, flags, and roofing slates.

Salt rock has latterly been worked near Carrickfergus. The quality is said to be superior to the Cheshire rock-salt, and the present annual produce is about 20,000 tons.

Agriculture, &c.—Ireland is essentially an agricultural country; and upon the cultivation of the soil the mass of the people depend for their subsistence. It was almost exclusively a pasturing country until the middle of the last century. That the soil of Ireland is, however, eminently fitted for tillage, appears from the evidence of every intelligent person qualified to

give a sound opinion, who has visited the country. Arthur Young, who travelled through it in 1776-78, says of Limerick and Tipperary—'It is the richest soil I ever saw.' Wakefield, in his 'Statistical Account of Ireland,' says, 'Ireland may be considered as affording land of excellent quality: some places exhibit the richest loam I ever saw turned up by a plough.' And the late Mr. McCulloch, in his valuable work on the 'Statistics of the British Empire,' confirms these statements. 'The luxuriance of the pastures,' he writes, 'and the heavy crops of oats that are everywhere raised, even with the most wretched cultivation, attest its extraordinary fertility.' Natural manures abound in most districts. The greatest portion of the soil lies on a substratum of limestone; marl is raised in many places, as is gypsum or sulphate of lime; coralline sand and seaweed are collected along the shores.

In the ten years from 1851 to 1861, no less than 784,952 acres of bog were reclaimed and converted into grass land. But land under bog and waste must not be considered as altogether unprofitable, as the large areas of bog distributed throughout the country afford the necessary fuel at a cheaper rate than coals could be procured.

The tenure of landed property in Ireland varies considerably. Formerly the custom prevailed of granting leases either in perpetuity, for 999 years, or for lives renewable for ever, with or without renewal fine. Hence some of the owners of very large estates receive a very small share of the actual profits. The leases commonly granted at present are for sixty-one, thirty-one, or twenty-one years, with very frequently a life or lives. Landlords ordinarily neither erect nor repair the farmsteads, and the maintenance and improving of the farm is, in too many instances, thrown on the tenant. Estates are of every extent, from a very small quantity to a very large number of acres. Grazing farms are large; the arable in general small, particularly in Ulster, in which province much of the land in several counties, particularly in those where the domestic manufacture of linen prevails, is parcelled out into very minute subdivisions. The practice of taking into cultivation large tracts of mountain bog or other land hitherto unreclaimed, is now very prevalent. The cottier system, by which the occupying tenant receives a patch of land in part or whole payment of wages, and that of rundale, in which a large tract is held by a number of individuals in common, are still kept up, though by no means to such an extent as formerly.

Few of even the moderate-sized farms are entirely under tillage, and the extensive farms, especially in the western and some of the midland counties, are devoted exclusively to pasture, or have a small portion of arable attached to a large share of permanent pasture. The farm buildings are therefore suited to these circumstances, and present a marked contrast to English and Scotch steadings erected for farms of similar extent and fertility.

Though now improving, the general husbandry of Ireland has long been in a backward state, owing to the minute divisions of land, the system of subletting, and the undue dependence of tenants upon landlords or their agents. To the effect of these circumstances in discouraging enterprise and paralysing effort, political agitation in time past contri-

buted. Besides the cereal produce, of which oats form the largest crop, as suited to the moisture of the climate, a considerable extent of surface is devoted to the growth of flax for the linen trade, chiefly in the northern province of Ulster, with limited spaces in other quarters. The light calcareous soil, the softness of the climate, and the fresh breezes which fan the island from the Atlantic, tempering the heat of the summer sun, conduce to the health and perfection of that delicate plant. It is usually sown in March or April, flowers about the beginning of July, and is considered ripe towards the end of August. The extent of land devoted to flax cultivation had steadily increased from 91,646 acres in 1858 to 301,693 in 1864. With a view to promote its cultivation in the south and west, the government granted in 1864 a sum of 2000*l.*, and in the following year 3000*l.*, to send out instructors to teach the farmers, and a great impetus was thus given to its growth. Among the green crops are potatoes, which had long formed the staple food of the Irish peasantry, till their memorable failure in 1845-47, when a government grant of 10,350,000*l.* was found necessary to prevent starvation.

Dairy produce and live stock, consisting of cattle and swine and poultry, are exported to an immense extent. The pig, especially, is an inmate of almost every peasant's cabin, is remarkably docile, and as carefully provided for as any member of the family. The animals are sent in large numbers to Bristol and Liverpool; and after supplying the local demands, the surplus stock, alive or cured, is sent to the metropolitan and other inland markets. The following table shows the extent under each of the principal crops in 1863 and 1864, and the increase or decrease in the latter year:—

Crops.	Extent Cultivated in		Increase or Decrease in 1864.	
	1863.	1864.	Increase.	Decrease
	Acres.	Acres.	Acres.	Acres.
Wheat, . . .	260,311	276,483	16,172	—
Oats, . . .	1,953,883	1,814,586	—	138,997
Barley, . . .	171,892	172,700	808	—
Bere and Rye, .	8,659	8,594	235	—
Potatoes, . . .	1,023,414	1,039,724	16,310	—
Turnips, . . .	351,436	337,355	—	14,081
Mangel Wurzel,	16,320	14,073	—	2,247
Cabbage, . . .	34,125	31,821	—	2,304
Flax, . . .	214,089	301,693	87,594	—
Hay, . . .	1,560,638	1,609,569	48,931	—
Total Increase,	5,594,777	5,607,198	12,421	

The total number of cattle in Ireland in the year 1864 was 3,257,309, being an increase of 113,078 over 1863; number of sheep, 3,363,068, being an increase of 54,864. In horses there was a decrease in 1864, the total number being 564,361, which was 18,617 less than in 1863; and pigs also decreased, the number amounting to 1,056,245, being 11,209 less than in 1863. The total value of live stock in Ireland in the year 1864 was computed at 30,085,082*l.* In 1859 its value was 35,368,259*l.*, showing a falling off to the extent of more than 5,000,000*l.* within a period of five years; but in 1865 the number again increased, and it may be observed that during the last ten years the oscillations

in the sum of the whole value of stock have pretty nearly balanced themselves, being a little above 30,000,000*l.*

Botany.—Generally speaking, the botanical characteristics of Ireland are identical with those of Great Britain. The oak, however, does not flourish, and the principal trees are the birch, aspen, alder, willow, blackthorn, and elm.

Ireland once had the name of the Island of Woods, from being covered with forests, and latterly acquired the poetical name of the Emerald Isle, from the perennial brilliancy of its verdure. Its Flora contains some rare varieties; the *Arbutus unedo* flourishes in Killarney; varieties of saxifrage and of ferns are found in the mountains of Kerry; Connemara, Benbulbin Mountain in Sligo, and Antrim county, abound in scarce Alpine plants; rare and hitherto unknown species of algæ have been discovered on various parts of the coast.

Zoology.—None of the larger carnivorous quadrupeds are found in Ireland, though the wolf and the bear were common up to a comparatively recent date. The fox is rare; and the badger and the otter are seldom met with, except in the neighbourhood of the Lakes of Killarney. The wild cat haunts the wooded districts, and two or three varieties of the weasel and marten occur.

The common squirrel has only recently been introduced. Of hares and rabbits numerous varieties exist, and in many localities their 'name is legion.' The mole is not found in Ireland, and while it can boast of the red deer, it lacks the roebuck. The fossil remains of a large species of deer, commonly known as the Irish elk, are frequently discovered in boggy localities. The golden eagle inhabits the wild mountainous districts.

The elk, or moose deer, was a native of the country; its bones have been found in several places: wolves were once so numerous that a price was set upon them, and the Irish wolf-dog kept for hunting them. Venomous animals are unknown; the moisture of the climate is destructive to them.

As is well known, from a tradition associated with St. Patrick, no snakes occur in Ireland; and the only reptiles which it possesses are a single species of lizard, and four of the order of *Batrachians*.

Fisheries.—Bounties to encourage the fisheries of Ireland, granted in 1764, and continued for several years, failed to place them on a productive footing. The experiment was repeated in 1819, when commissioners were appointed, with power to grant bounties to persons building fishing boats of a certain tonnage, and for the curing of herring and some other kinds of fish. An annual sum of 5000*l.* was placed at their disposal, the application of which was afterwards limited to the building of piers and the repairing of boats; a large portion of the grant was also employed as a loan fund, to enable the poorer fishermen to procure the necessary gear on advantageous terms. The commission was revoked in 1830, and no further measures were adopted respecting the fisheries until 1842, when the Board of Public Works were appointed commissioners for their improvement and regulation. The country is portioned out into forty coast fishery districts, and seventeen salmon and inland fishery districts. In 1848 the Act of 11 & 12 Vict., c. 92, passed, which first imposed a

license duty on all engines used for the capture of salmon and trout, and constituted, for the first time, an organized body for the general protection of the salmon fisheries. The amount of license duty paid in Ireland in 1864 was 7002*l*.

The number of vessels and hands engaged in the sea fisheries in 1864 was:—

Vessels and boats, ...	9,300
Men and boys, ...	40,946

The herring fishery is prosecuted chiefly on the east coast of Ireland by a fleet of between 200 and 300 vessels from Cornwall, which for several weeks continue profitably employed in the capture of fish for the Dublin and Liverpool markets. The native fishermen of Howth are now successfully competing in energy and skill, number and character of boats, and superior fishing equipments. The Irish markets are still extensively supplied with cured fish from Scotland and the Isle of Man. The number of barrels of herrings imported into Ireland in 1864 was 55,420.

Notwithstanding that in her sea fisheries Ireland has an almost unbounded source of wealth—for there are unlimited supplies of cod, ling, hake, herring, pilchards, &c.—yet strange to say, they are comparatively neglected. An Irish sea fishery company under the Limited Liability Act has just been established (1866) for the purpose of developing the great resources of the fisheries on the Irish coast.

Trade and Commerce.—The staple manufacture of Ireland is that of linen, which has long been established in the country, and to promote which has always been a favourite idea with the government. It was formerly carried on chiefly by hand-loom at the homes of the weavers, and at one time had begun to seriously decline, but of late years it has greatly revived in consequence of the application of machinery to the spinning of yarn, and of the introduction of the power-loom in weaving. The export of linen yarns and linen manufactures from Ireland to Great Britain and foreign countries, was in 1862, 6,292,000*l*.; in 1863, 8,084,000*l*.; and in 1864, 10,327,000*l*. The number of spindles in operation for spinning flax in Ireland, in 1864, was 761,060; 200,000 persons are altogether employed in connection with the trade, and the amount invested in buildings, machinery, and the requisite floating capital, is estimated at 3,000,000*l*. The estimated quantity of flax grown in Ireland in the seven years ending 1864 was 216,897 tons, or on an average 30,985 tons per annum. The number of acres sown in 1863 was 214,092; the average product, 64,227 tons. In 1864 there were 301,693 acres, or an increase of 87,594 acres. The trade is almost entirely confined to the province of Ulster—the town of Belfast being the principal seat of its manufacture.

A great source of employment for females has recently sprung up in the North of Ireland, in the working of patterns on muslin with the needle. Belfast is also the centre of this manufacture, which employs about 300,000 persons, chiefly females, scattered through all the counties of Ulster and some localities of the other provinces. About forty firms are engaged in the trade, some being Irish houses and others agents for Scotch firms, and the gross value of the manufactured goods amounts to about 1,400,000*l*.

Cotton, woollen, silk, and paper manufactures are

carried on in different parts of the country, but only to a comparatively limited extent, the Irish character not being suited to the restraints and confinement necessary both to factory life and mining operations.

The exportation of the agricultural produce of the country has always been the principal commercial business carried on in Ireland. During the revolutionary war, the country furnished a large share of the provisions for the army and navy, and it still sends supplies to the colonial markets. But Great Britain is by far the best and most extensive market for all sorts of Irish produce. By much the greater part of the export trade is carried on by the cross-channel navigation, chiefly to Liverpool, Bristol, and Glasgow, the staple articles being black cattle, sheep, swine, salted provisions, grain, flour, butter, eggs, and linen. The trade with the colonies and with foreign parts is comparatively inconsiderable. The cessation of the collection of the duties on the cross-channel trade, which took place in 1825, has taken away the means of estimating the amounts of imports and exports to and from Great Britain since that period.

The number of vessels registered as belonging to Ireland is 2300, of about 250,000 tons burthen. The total entries at the different ports in 1864 were 27,518 (4,084,613 tons), and the clearances 13,665 (2,722,592 tons).

Railways, Telegraphs, and Canals.—The chief features of the railway system in Ireland are—1st, the gauge, which is 5 feet 3 inches, and is compulsory; 2nd, the heavy weight of rails (on some lines 90 lbs. per yard), the permanent character and moderate cost of the works generally, and a singular and almost entire freedom from tunnels. The average cost of the lines that are open has been, including carrying stock, &c., about 16,000*l*. per mile. The Irish railways are exempt from passenger duty, and have participated to a considerable extent in the government loans. The portion of capital in Irish railways held by resident proprietors has been estimated at 1,500,000*l*. in 1841, at 11,000,000*l*. in 1859, and at 13,000,000*l*. in 1865. There are now (1866) nearly 2000 miles open.

Lines of electric telegraph wires connect the principal towns, and submarine communication has existed between Ireland and England for many years.

The principal canals of Ireland are the Royal Canal, commenced in 1789, from Dublin to Tarmonbarry, on the Shannon, with a branch from Killashee to Longford; total length, ninety-seven miles; the Grand Canal, commenced in 1765, from Dublin to the Shannon at Shannon Harbour. It has several branches. The length of the main trunk, from the Liffey to the Shannon, is eighty miles, and thence to Ballinasloe, fifteen miles, being ninety-five miles in a western direction; that of all the branches is 65½; total length, 160½. The Ulster Canal proceeds from Charlemont, on the Blackwater river, by which it communicates with Lough Neagh, and passing by Monaghan and Clones, enters the upper Lough Erne. Its length is forty-eight miles.

Shannon Navigation.—The River Shannon rises in Quilca Mountain, in Leitrim county, passes southward between Connaught and Leinster to Limerick, forming in its course several large lakes, the principal of which are Loughs Allen, Reagh, and Derg, and turning westward, discharges itself into the Atlantic

through a large estuary between the counties of Clare and Kerry, a distance of 254 miles. The navigation is open for traffic throughout its entire length, between the northern extremity of Lough Allen and Limerick, a distance of 143 miles in a direct course; but by adding the Boyle branch of nine miles, and the Strokestown branch of six miles, a total length of river and canal navigation of 158 miles is now open; of which 129 miles, viz., from Killaloe to Leitrim, including the two branches above mentioned, are suited to the navigation of large steamers. In the main river of 115 miles the entire fall amounts only to thirty-five feet, which has been overcome by the erection of five locks. This important navigation, which occupies nearly a central position between the east and west coasts of Ireland, is connected with Dublin by means of the Grand and Royal Canals.

Incumbered Estates.—Much of the land in Ireland having long been so loaded with debt that improvements were well-nigh impossible, and many of the proprietors being reduced to a chronic state of bankruptcy, in 1848, the Act 11 & 12 Vict., c. 48, to facilitate the sale of incumbered estates in Ireland, was passed, but owing to the defectiveness of its construction it proved wholly inoperative; and in the following year it was superseded by the Act of 12 & 13 Vict., c. 77. Under the provisions of this Act a royal commission was issued, with the title of 'The Commission for sale of Incumbered Estates in Ireland,' having three commissioners appointed by the Crown; and to be a court of record, with powers to frame rules for regulating its proceedings.

The commissioners commenced their sittings in October, 1849. The total number of petitions presented in the eight years ended 31st August, 1857, was 4413. Of these 1363 were lodged by owners; and the court made 3547 absolute orders for sale. The first sale was held on the 21st of February, 1850.

The gross amount produced by sales from October, 1849, up to August, 1859, was 25,190,839*l*. The court distributed to creditors 24,229,027*l*., inclusive of 3,692,611*l*. allowed to incumbrancers who became purchasers. A sum of 961,809*l*. remained at that date in hand to satisfy unadjusted claims.

In 1858, an Act was passed extending the powers of the Incumbered Estates Court for the sale of incumbered properties to properties that are unincumbered. By this Act the judges and officers of the former court are transferred to a new court, called 'The Landed Estates Court,' which commenced its sittings on 1st November. Since this date the amount of sales made by the court have been nearly 10,000,000*l*., so that altogether by means of these tribunals land of the value of 35,000,000*l*., and comprising one-seventh of the whole area of Ireland, has within the last seventeen years been brought into the market and transferred from necessitous to solvent hands.

Political Divisions and Population.—Ireland is now divided into the four provinces of Leinster, Munster, Ulster, and Connaught; Meath being merged into Leinster and Ulster. These are subdivided into thirty-two counties, besides the eight small exempt jurisdictions of Dublin, Cork, Kilkenny, Limerick, Waterford, Carrickfergus, Drogheda, and

Galway; the first five of which are styled counties of cities, the remaining three, counties of towns. The counties are divided into 316 baronies, and again into 2422 parishes. The smallest political divisions are called townlands, and in some parts, ploughlands. Irrespective of those divisions the whole of the country is divided, under the Poor Law Act, into 163 unions, subdivided into 3439 electoral divisions.

The following is the area in acres and population enumerated in 1851 and 1861, in each county and county of a city or town (including the army and navy serving in Ireland):—

Provinces, Counties, and Cities.	Area in Statute Acres.	Population.		Increase or Decrease in the Number of Persons between 1851 and 1861.	
		1851.	1861.	In- crease.	De- crease.

1861	5,798,967	—	753,418

The returns for 1861 give a density of population of 181 inhabitants per square mile, showing that Ireland is more thickly populated than France, but slightly less than Germany. Of the population in 1861, there were 2,837,370 males and 2,961,597 females. The decrease was $11\frac{1}{2}$ per cent. during the ten years from 1851.

The decrease is most apparent in the city of Kilkenny and town of Galway, and the counties of Tipperary, Wexford, Meath, Kilkenny, King's, Clare, Waterford, and Cork. The only localities in which an increase of population has taken place are Dublin county, and the towns of Carrickfergus and Belfast, in which latter locality it amounts to 20,476 on the returns for 1851. The decrease in the number of families between 1841 and 1851 was 268,468, or 18·23 per cent.

The earliest known inhabitants of the island were of Celtic origin; these intermixed in the south and west with Milesian tribes from Spain; in the maritime districts of the east and south-east, with Danes and Anglo-Normans; and in the north with the Scotch, who settled there in great numbers in the reign of James I.; subsequently, many English families settled in the country, and small colonies of French emigrants settled in Dublin, the Queen's county, and Lisburn in Antrim; some Germans, called Palatines, in Tipperary.

Public Works.—The Board of Public Works in Ireland has in charge the disposal and regulation of the loans and grants for public works, landed improvements, and drainage; also the expenditure for public buildings, roads and bridges, fisheries, piers and harbours, and certain lines of inland navigation.

The drainage works executed through the medium of loans under the Land Improvement Acts, have, as a whole, been tolerably successful; and improvements in agriculture, especially in the spread of rotative husbandry and the introduction of green crops, have generally followed the completion of the works. A number of loans which had been sanctioned have been relinquished or cancelled by the Board, in consequence of which a sum amounting to 250,000*l.* remains unappropriated out of the fund of 2,000,000*l.* voted by Parliament for the Land Improvement service.

The total area that has been thorough-drained amounts to 250,000 acres, which has been effected at an average cost of 5*l.* per acre.

Government.—The executive government is vested in a lord lieutenant, assisted by a privy council, appointed by the Crown and indefinite in number, the bishop of Meath being always one, *ex officio*; and by a chief secretary, a member of the House of Commons. In the absence or vacancy of the lord lieutenant, his place is supplied by lords justices, who generally are the primate or the archbishop of Dublin, the lord chancellor, and the commander of the forces. Each county is in charge of a lord lieutenant, generally a peer, an indefinite number of deputy lieutenants and magistrates, who act gratuitously, and one or more resident paid magistrates, all appointed by the Crown during pleasure. The counties of cities and towns, and the boroughs, are governed by their own magistrates.

Representation.—The country is represented in the Imperial Parliament by 4 Spiritual and 28 Temporal Peers, and 105 Commoners; of which latter class 64 represent the 32 counties, 2 Dublin University, 12 the cities and towns of Dublin, Cork, Limerick, Waterford, Belfast, and Galway, and 27 the boroughs. The Act 13 & 14 Vict., c. 69, was passed in 1850 to amend the representation; and in addition to those persons previously qualified to register and vote in county elections, occupiers of any tenements rated in the last poor rate at a net annual value of 12*l.* and upwards, are entitled to vote in elections for counties, also owners of certain estates of the rated net annual value of 5*l.* In boroughs, occupiers rated in the last poor rate at 8*l.* and upwards are entitled to vote, subject to certain limitations. By this Act the polling at contested elections is to continue in counties for two days only, and in cities and boroughs for one day only. The number of electors was, by the last returns, 172,000 in the counties, and 30,000 in the cities and boroughs; total, 202,000.

Religion and Education.—By a special provision, inserted in the Act 23 & 24 Vict., c. 62, for taking the census of Ireland upon April 8, 1861, it was ordered that there should be an inquiry into the religious creed of the population. It was the first occasion on which this subject formed a portion of the decennial census; nevertheless, it is stated to have given rise to few, if any, complaints and objections. The return, therefore, may be admitted as tolerably correct. The numbers in the principal religious denominations, as estimated by the commissioners of public instruction in 1834, and ascertained by the census commissioners in 1861, were as follows:—

Profession.	1834.	1861.
	Number.	Number.
Established Church, . .	853,160	693,357
Roman Catholics, . . .	6,486,060	4,585,265
Presbyterians, ...	643,058	523,291
Protestant Dissenters, .	21,822	76,661
Jews, ...	—	398
Total, ...	7,954,100	5,798,967

In 1834 there were 100 Roman Catholics to 13·25 members of the Established Church, and in 1861 the proportion was 100 to 15·38.

Previously to the Church Temporalities Act, 3 & 4 Will. IV., c. 37, the country was divided for eccle-

statistical purposes into four archbishoprics, nearly identical with the four civil provinces, but taking their names from the cities which were the seats of the sees. By that Act the archbishoprics of Cashel and Tuam were reduced to bishoprics, and the whole of Ireland divided into two provinces, by a line drawn from the north of Dublin county to the south of Galway bay, and the bishoprics were reduced to ten.

The revenues of the suppressed bishoprics, together with those of suspended dignities and benefices, and disappropriated tithes, were vested by the Church Temporalities Act in the Board of Ecclesiastical Commissioners, to be applied by them to the erection and repairs of churches, to the providing for the church expense which had been defrayed by vestry rates, and to other ecclesiastical purposes. The revenues of the suppressed sees are now nearly £70,000 per annum—the income of the Commissioners being altogether over £150,000.

From a recent parliamentary return it appears that the number of adherents to the Established Church, and the income of the several Irish dioceses in 1834 and 1861 were as follows:—

Dioceses.	Number of Members of the Established Church in		Revenues of the Estab. Church in each Diocese in
	1834.	1861.	1861.
Armagh and Clogher, . .	207,371	150,386	£82,930
Dublin and Kildare, . .	120,506	112,766	55,103
Meath, ...	25,626	16,321	34,828
Derry and Raphoe, . .	83,857	65,603	56,153
Down, Connor, & Dromore,	136,650	152,722	44,785
Kilmore, Elphin, & Ardagh,	81,046	53,165	47,410
Tuam, Killala, & Achonry,	22,755	17,156	27,539
Ossory, Ferns, & Leighlin,	57,424	35,663	62,248
Cashel, Emily, Water- ford, and Lismore, . .	19,307	13,853	43,093
Cork, Cloyne, & Ross, . .	55,156	43,228	65,423
Killaloe, Kilfenora, Clon- fert, & Kilmacduagh, }	24,801	15,906	28,789
Limerick, Ardfer, and Aghadoe, ... }	18,651	15,103	32,117
Total, ...	853,160	691,872	£580,418

The Roman Catholic hierarchy consists of four archbishops, whose sees are in Armagh, Dublin, Cashel, and Tuam, and twenty-four bishops. [BISHOPRIC.] The bishops are nominated by the pope, generally from a list of names submitted to him by the bishops of the province and the clergy of the vacant diocese. In case of expected incapacity from age or infirmity, the bishop names a coadjutor, who is usually confirmed by the pope. Every diocese has a dean and an archdeacon, the former appointed by the cardinal protector at Rome, the latter by the bishop; but these dignities are without jurisdiction or emolument. The whole of the clergy are supported solely by the voluntary contributions of their flocks. The episcopal emoluments arise from the parish in which the bishop officiates, from marriage licenses, and from the cathedraicium, an annual sum varying from 2*l.* to 10*l.*, paid by each incumbent in the diocese. The parochial clergy are nominated exclusively by the bishop. The number of priests in Ireland in 1864 was 2291, of whom 1222 were educated at Maynooth College. Their incomes arise from fees on marriages,

baptisms, and deaths, on Easter and Christmas dues, and from incidental voluntary contributions, either in money or labour. All the places of public worship are built by subscriptions. There are numerous monasteries and convents; the latter are supported partly by sums, usually from 300*l.* to 500*l.*, paid by those who take the vows in them, and partly by the fees for the education of the daughters of respectable Roman Catholics. The friars and nuns also devote themselves to the gratuitous education of the children of the poor. Candidates for clerical ordination, formerly under the necessity of obtaining their education in continental colleges, are now educated at home; the principal clerical colleges are the Royal Colleges of St. Patrick, Maynooth, supported by grants of public money and by pensions from the students, the Catholic University, Dublin, and the College of St. Patrick, Carlow, and St. Jarlath, Tuam, by voluntary contributions.

The Presbyterians, who are found chiefly in Ulster, are formed into congregations, each of which is under the ecclesiastical government of a court called a session, consisting of the minister and elders of the congregation. An indefinite number of the ministers of these congregations, with a lay elder for each, constitutes a presbytery, which has the charge of the congregations represented in it. Delegates from each of these presbyteries, consisting of all the ministers, with a lay elder for each, constitute the general assembly, which is presided over by a moderator chosen annually, and regulates the ecclesiastical concerns of the body. The General Assembly of the Presbyterian Church in Ireland comprises about 550 congregations, arranged under 40 presbyteries. The ministers are supported by voluntary contributions, the rents of seats or pews, and the *Regium Donum*, or royal gift, first granted in 1672 by Charles II., who gave 600*l.* of 'secret service money' to be distributed in equal portions among them annually. The grant was discontinued towards the close of his reign and during that of James II., but was renewed by William III., who augmented it to 1200*l.* a year. In 1784 the amount was increased to 2200*l.*; in 1792 to 5000*l.*; and in 1803 a classification was made according to the number of families in each congregation and the amount of the minister's voluntary stipend, by which those of the 1st class received 100*l.* annually; of the 2nd, 75*l.*; and of the 3rd, 50*l.* In 1831 the system of classification was altered, and 35 (1st class) ministers now receive 92*l.* 6*s.* 2*d.* each, and 512 (2nd class), 69*l.* 4*s.* 8*d.* each, per annum. As the ministers in the first class die, their successors will only receive the latter amount. The number of members of other denominations of Protestant dissenters in Ireland is very limited.

The institutions for communicating instruction are—the University of Dublin; the Queen's Colleges of Belfast, Cork, and Galway, in connection with the Queen's University in Ireland (established in 1850); the College of St. Columba, near Dublin; the General Assembly's College, Belfast; the Belfast Academical Institution; the Roman Catholic University, Dublin; the Roman Catholic Colleges of St. Patrick, Maynooth; St. Jarlath's, Tuam; St. Patrick's, Carlow; Armagh, and Thurles; St. Kyrn's, Kilkenny; Clongowes, Clane, and the Missionary College of All Hallows, Drumcondra, near Dublin; endowed

schools, parochial school, national education schools, church education schools, &c.

In 1833 the grants of public money for the education of the poor were intrusted to the charge of the lord lieutenant, to be expended on the instruction of the children of every religious denomination, under the superintendence of commissioners appointed by the Crown, and named 'The Commissioners of National Education.' The principles on which the commissioners act are, that the schools shall be open alike to Christians of every denomination; that no pupil shall be required to attend at any religious exercise, or to receive any religious instruction which his parents or guardians do not approve, and that sufficient opportunity shall be afforded to the pupils of each religious persuasion to receive separately, at appointed times, such religious instruction as their parents or guardians think proper. This system of united education is one which does not exclude children of any denomination, while it admits to a participation of its benefits those of every religious creed who may wish for instruction without interfering with any conscientious scruples. The duty of the commissioners consists, therefore, in guarding against any infraction of these fundamental principles from any quarter; in establishing regulations as to details, so as best to secure the general efficiency of the system; and in granting or refusing assistance to every applicant, for erecting and maintaining suitable buildings for schools, and for furnishing them with books and other requisites.

In 1845 the commissioners were incorporated under the name of 'The Commissioners of National Education in Ireland,' with power to hold lands to the yearly value of 40,000*l.*, to erect and maintain schools where, and as many as they shall think proper, to grant leases, &c. The commissioners (who must not be more than fifteen in number, and are removable at the pleasure of the lord lieutenant) being enabled, under this charter, to accept conveyances of property in their corporate capacity, have resolved, in every case of making a grant for building a national school-house, to take upon themselves the trust for the public, and the charge of repairs; leaving the local managers, who in general are not the trustees, the rights they now possess as to the appointment and removal of teachers, and the general regulation of the school.

The number of schools under the superintendence of the commissioners in 1834 was 1106, with 145,521 pupils on the rolls, and having a parliamentary grant of 35,000*l.* In 1864 the schools had increased to 6263, the pupils to 870,401, and the parliamentary grant to 251,016*l.*

According to the census of 1861, the proportion of the population able to read and write had risen, since 1851, from 33 to 41 per cent.; the number of those who could read only remained stationary at 20 per cent.; and the number of those who could neither read nor write had fallen from 47 to 39 per cent.

Judicial Divisions and Criminal and Pauper Statistics.—The judicial establishment of Ireland consists of the Chancellor, the Lord Justice of the Court of Appeal in Chancery, the Master of the Rolls, four judges in each of the Courts of Queen's Bench, Common Pleas, and Exchequer, those of the Exchequer being styled Barons, three judges in the

Landed Estates Court; the Bankrupt and Insolvent Court, with two judges, and the judges of the Courts of Probate and Admiralty; and a Chairman of Quarter Sessions for each county, the county of Cork having two. The superior courts are held in Dublin; their terms of sitting are Hilary, Easter, Trinity, and Michaelmas. Two of the judges hold assizes for criminal and civil pleas, in each county, in spring and summer every year, for which purpose the country is divided into six circuits. Two of the judges also hold a general gaol delivery for Dublin every six weeks.

The decrease in the number of criminals in Ireland during the last fifteen years is altogether unexampled—amounting altogether to 60 per cent. In 1850 not less than 17,108 persons were convicted of various offences; in 1855 the number had been reduced to 5220, and in 1860 to 2979. In 1865 there was a slight increase on the latter number—the convictions then being 3000. This satisfactory result is no doubt partly due to the improvement of the police and judicial organization; but, besides being a sign of social progress, it must in a great measure be credited to Sir Walter Crofton's system of prison discipline, which is a plan of preparing men for liberty and for an honest life by a gradual emancipation earned by their own good conduct. It has gone far to abolish the class of regular criminals; and from an inquiry just instituted by a distinguished English philanthropist, it has been ascertained that the employers of the released convicts in Dublin—builders and other tradesmen—universally testify to the completeness of the reformation of the men who were once professed thieves and felons. One only form of crime remains beyond the reach of any force yet in action—the cruel 'agrarian murders,' which year after year, as the autumn closes, send desolation into one home after another. In the matter of pauperism, also, the improvement of the country is very clearly proved by the returns. The total number of persons in receipt of relief in 1850 was 307,970; in 1865, only 69,217.

Military Divisions.—The staff of Ireland consists of the departments of commander of the forces, adjutant-general, and quartermaster-general, under which are those of the judge-advocate-general and medical director-general. The military divisions are according to the following districts:—Dublin, or Northern District, Dublin; Cork, or South-Western District, Cork. For Recruiting Service—Northern District, Head-quarters, Belfast; Centre District, Dublin; Southern District, Cork. The number of troops stationed in Ireland in 1864 was 24,000.

The Militia of Ireland, when embodied, consists of 12 regiments of artillery (5002 men) and 35 regiments of infantry (26,347 men); total, 31,349 men.

The Constabulary of Ireland is very efficient. The first regular police force was established in 1814. The reserve force was established in 1839. Originally the expense was paid partly by grand jury presentments, and partly out of the consolidated fund; but the Act 9 & 10 Vict., cap. 97, passed in 1846, provides that the whole expense shall be borne by the consolidated fund, except a moiety of the cost of additional constabulary force applied for by the Magistrates of any county or district, or of the reserve force when employed therein, or of an

increased force stationed there by the lord lieutenant. The Act 6 Will. IV., c. 13, likewise authorized the lord lieutenant to appoint resident stipendiary magistrates, to act in disturbed districts, or in districts where, owing to the absence or non-residence of the local magistrates, or for any other sufficient cause, it should appear to be expedient. The constabulary force, on the 1st January, 1865, consisted of 11,824 men, and 376 horses. Its total maintenance for the year 1864 amounted to 696,310*l.*, including the expenses of 72 stipendiary magistrates, whose annual salaries are—22 at 500*l.*, 30 at 400*l.*, and 20 at 300*l.*, with extra allowances for forage, travelling expenses, &c. The expense of the force charged on the consolidated fund in 1864 was 680,606*l.*; and on the counties, cities, and towns of Ireland, for augmentations, conveyance of prisoners, &c., 15,784*l.*

Revenue, Expenditure, and Debt.—The public revenue collected in Ireland averages about 6,750,000*l.* per annum. Of this sum 2,750,000*l.* is derived from excise duties—chiefly in the 10*s.* per gallon levied on the 5,000,000 gallons of whisky consumed yearly—and 2,250,000*l.* from the customs. The expenditure generally exceeds the income by at least 500,000*l.*, and often considerably more, but this is in a great measure owing to the very large military and constabulary force maintained in the country. The unredeemed debt of Great Britain and Ireland, in British currency, as in the Treasury Return of 15th April, 1824, was:—

Great Britain.	Ireland.	Total.
1801, 420,305,944 <i>l.</i>	26,841,219 <i>l.</i>	447,147,163 <i>l.</i>
1817, 688,820,032 <i>l.</i>	107,380,158 <i>l.</i>	796,200,190 <i>l.</i>
1818, 755,737,972 <i>l.</i>	21,004,430 <i>l.</i>	776,742,402 <i>l.</i>

On the 5th January, 1818, the unredeemed debt of Great Britain was increased 66,917,940*l.*, out of 86,375,728*l.* taken from the unredeemed debt of Ireland as it stood on the 5th January, 1816. In the intervening time there was transferred to the names of the Commissioners for Reduction of National Debt, 22,348,528*l.* The action of the sinking fund, therefore, covered all additions in the year, and provided for the diminution appearing on the 5th January, 1818. No separate account of the debt of Ireland has been kept since its consolidation with that of Great Britain in 1817, per Act 56 Geo. III., cap. 98.

History and Antiquities.—All the early names of Ireland, such as *Iris*, *Erim*, *Hibernia*, are believed to be derived from the same Celtic roots. The *Scoti*, who were in possession of the island at the time of the introduction of Christianity, appear to have been to a great extent the successors of a people whose name and monuments indicate a close affinity with the Belgæ of Southern Britain. The monuments and relics which attest the presence of a people considerably advanced in civilization at some period in Ireland, such as cyclopean buildings, sepulchral mounds containing stone chambers, mines, bronze instruments and weapons of classic form and elegant workmanship, would appear to be referable to some of the predecessors of the *Scoti*.

The *Erse*, a dialect of the Celtic, is the native language, and is now chiefly used in the west and south part of the country.

Their dark complexion, and smaller and more

slender form of body, as well as their more volatile temperament, distinguish the Irish from the Saxons.

The general conversion of the Irish Scots to Christianity took place in the earlier and middle portion of the fifth century. The principal instrument in effecting the change was St. Patrick, who landed in Ireland on this mission in the year 432. A considerable advance in civilization followed the introduction of the new religion. Greek and Roman literature got some footing among the clergy, and an improved system of architecture became requisite for religious edifices. The Irish round towers are now generally ascribed to an ecclesiastical origin, and are supposed to have been erected during the sixth, seventh, and eighth centuries. Extensive monasteries were also founded, in which religion and learning were zealously cultivated, and from which numerous missionaries issued, and carried the doctrines of Christianity, under great difficulties, into the still pagan countries of Europe. Many students of distinction, from England and the Continent, frequented Ireland, and received gratuitous instruction at this period. The country was torn by civil contests, from the eighth to the twelfth centuries, between the kings and chiefs. In 1174 Henry II. of England took possession of the island with the formal sanction of the Pope, and made the native kings and chiefs his tributaries. The country was portioned out among the Anglo-Norman conquerors. In the twelfth year of the reign of King John, the division into counties took place, and appears to have embraced almost the whole of Ireland, though through subsequent reverses most of the counties in Ulster and Connaught ceased to be considered shire-ground. English laws and customs were to some extent introduced; but the great barons, finding the Irish laws more congenial to arbitrary authority, gradually assumed the character of despotic chieftains; so that on the accession of King Henry VIII. there was only an inconsiderable tract along the eastern coast in which the English law was fully recognized.

In this and the succeeding reigns of Elizabeth and James I., the English government having now the double motive of effecting a religious as well as a civil reformation in Ireland, applied themselves with great energy to the recovery of their authority, and, after a tedious series of rebellions and confiscations, succeeded at length, in the beginning of the seventeenth century, in making the entire island shire ground, and planting a numerous Protestant proprietary in Ulster. In 1641, the Irish, taking advantage of the disordered state of England, rose in insurrection and massacred nearly 40,000 Protestants. The country remained in a state of anarchy till 1649, when it was thoroughly reduced by Cromwell. At the revolution in England in 1688, most of the Irish took the part of James II., and again rose in rebellion, which lasted from 1689 to 1692. At its conclusion most extensive confiscations followed; and a system of much severity was adopted towards the political leaders; yet notwithstanding the harshness of the penal laws from time to time enacted against Roman Catholics, the country generally prospered during the century of uninterrupted tranquillity that ensued. Another outbreak occurred in 1798; but this, being likewise suppressed, led the way to the Act of Union, by which the Parliament

of Ireland, which had of late years enjoyed an absolute independence of all power but the Crown, was merged in that of the United Kingdom in 1800.

In 1829 the Roman Catholics, who had greatly increased in Ireland, were emancipated from many of the penal laws which pressed upon them. In 1832 the Irish Reform Bill passed. About the same year, the agitation for a repeal of the legislative union with Ireland commenced, and was continued almost yearly to 1849. In 1833 and 1836 Acts were passed by which several of the bishoprics were incorporated with others, and regulations were made for the improved application of the revenues of the church. In 1838 a poor law for Ireland was first enacted, which has been altered, amended, and extended by subsequent Acts. In 1838, also, an Act was passed for commuting Irish tithes into rent-charges. In 1840 a law was put into operation in Ireland, similar to the Municipal Reform Act of England. In the summer of 1842 food riots in many parts of Ireland bore witness to the impoverished state of the peasantry. Political agitation reached a great height in Ireland in 1843. The measures advocated were—the total abolition of the tithe rent-charge; fixity of tenure for occupying tenants; encouraging Irish manufactures; universal suffrage and vote by ballot; and abandonment of the new poor law. Two great meetings were held, but another was prevented by the government, and Mr. O'Connell and several other persons were tried for sedition. These trials, and the appeals, and 'writs of error,' consequent thereon, occupied public attention during a great part of 1844. Mr. O'Connell was eventually acquitted on purely technical grounds; but the blow dealt by the British government was not the less effectual, and the repeal agitation never again rose to any degree of importance. In the same year another step was made towards the removal of penal statutes against the Roman Catholics of Ireland. In 1845 two important Acts were passed: one for placing on an improved footing the Roman Catholic College of Maynooth; and the other for enabling the Crown to endow new colleges in Ireland. The potato crop of this year was almost wholly diseased; a circumstance which led immediately to the adoption of large plans for relief, and indirectly to the repeal of the corn laws. The year 1846 exhibited the effects of this failure of the potato crop in starvation and insurrection. The spring of 1847 brought with it the full horrors resulting from the famine; many thousands perished from actual hunger, and thousands more from fever, notwithstanding the unprecedented aid derived from England and elsewhere. In August nearly 3,000,000 rations of food were daily distributed to the suffering Irish by the relief commissioners. By the month of October outrages and murders became very frequent, and the government had to adopt stringent measures for their prevention. In 1848 the revolutionary party attained great influence, and carried on those proceedings which led to the conviction and transportation of Mr. Smith O'Brien, Mr. Mitchell, and others.

Although the effects of the potato blight were so terrible at the time, it undoubtedly had the good result of breaking up the vicious circle into which the evils of Ireland had run; a peasantry ill-fed and ill-housed, yet satisfied to live in misery, since living

was just possible, rather than emigrate, or incur harder labour than the culture of the miserable plot of potato-ground and the care of the swine; and a landholding class, burdened with debt and charges, and unable to expend on the land which supported them the capital necessary to render it productive. Famine and the exodus [EMIGRATION] mitigated the difficulties of the peasant, and the Incumbered Estates Court, previously noticed, those of the landlord; and, during the last ten years, Ireland has experienced such an amount of material prosperity as could never have been realized under the former system. It is true there is still room for great improvement, and the vast resources of the country require to be much more fully developed before its position can be said to be thoroughly satisfactory; but the results which have already been accomplished justify sanguine expectations as to the future. No outbreak of a serious character has occurred since 1848 except the Fenian movement of 1865–66, which became sufficiently formidable to require the suspension of the Habeas Corpus Act and other stringent measures for its suppression. It is satisfactory, however, to note that from this last movement the more respectable classes have entirely held aloof.

(Thom's *Irish Almanac*, 1866; *Statesman's Year Book*, 1866; Parliamentary Papers, and Communications from Ireland.)

IRELAND ISLAND. [BERMUDAS.]

IRELAND, NEW. [NEW IRELAND.]

IRELAND, REV. DR. JOHN, Dean of Westminster, was born at Ashburton, Devonshire, in 1761. He was the intimate friend and associate of William Gifford, translator of Juvenal; and, like him, he was of very humble origin, being the son of a butcher in the same town. They were associates in the Grammar School at Ashburton; and Gifford, in the preface to his edition of Ben Jonson, thus alludes to his old friend Dr. Ireland, on his elevation to the deanery of Westminster. 'With what feelings do I trace the words, "The Dean of Westminster!" Five and forty years have now passed over my head since I first found Dr. Ireland, some years my junior, in our little school, at his spelling-book. During this long period, our friendship has been without a cloud; my delight in youth, my pride and consolation in old age!' Dr. Ireland's first promotion in the church was to the vicarage of Croydon, in Surrey, to which he was collated, in 1793, by Archbishop Moore. In 1802 he was promoted to a prebendal stall in the collegiate church of Westminster; and on the death of Dr. Vincent, in 1816, he was installed to the deanery, and also succeeded to the rectory of Islop, which is in the patronage of the Dean and Chapter of Westminster.

Dr. Ireland was not only a warm patron and friend of learning, but he also extensively applied his talents to the walks of literature. In conjunction with his friend Mr. Canning, he was one of the principal writers who aided Mr. Gifford in the early volumes of the *Quarterly Review*. He was also the author of 'Vindiciæ Regiæ, or a Vindication of the Kingly Office,' 'Paganism and Christianity Compared,' 'Nuptæ Sacre, an Inquiry into the Scriptural Doctrine of Marriage,' with numerous lectures, discourses, and sermons, on a variety of subjects. Having no family he was enabled to apply his large

property to the most useful purposes. He was the founder of four scholarships in the University of Oxford, of 30*l.* per annum each. To Westminster School he gave 500*l.*; to the school where he had been educated 2000*l.*; to Oriel College, Oxford, 2000*l.* for an exhibition; and 10,000*l.* to the University for the Professor of 'The Exegesis of the Holy Scripture.' He also left by his will several large sums in reversion for different charitable objects:—to the Western Dispensary he left 1000*l.*; to the Devon and Exeter Hospital, 2000*l.*; to the Westminster Hospital, 2000*l.*; for a chapel in Westminster, 5000*l.*; to King's College, 2000*l.*; to trustees for poor persons in Ashburton, 1000*l.*; with other liberal bequests and legacies. He died in 1842.

IRENÆUS, SAINT, bishop of Lyons in Gaul, was a pupil of Polycarp, in Asia Minor, and a presbyter of Pothinus, bishop of Lyons. After the martyrdom of Pothinus in 177, Irenæus was elected bishop of Lyons. He discharged the duties of his office with diligence, and is said to have been the means of converting many pagans to the Christian religion. The place of his birth is not known; but it is probable that he was a native of Asia Minor. It is commonly supposed that he suffered martyrdom in the beginning of the third century; but even that is uncertain.

With respect to the works of Irenæus, we learn from Eusebius ('Hist. Eccl.,' v. 20) that he wrote several letters against the heretics and false prophets who at Rome corrupted the true doctrine of the church; one to Blastus, concerning schism; another to Florinus, concerning the monarchy, or that God is not the author of evil; another concerning the number eight, and also a discourse against the Gentiles, entitled Concerning Knowledge; another inscribed to a brother named Marcianus, being a demonstration of the apostolical preaching; and a little book of divers disputations. Irenæus also wrote a letter to Victor, bishop of Rome, concerning the controversy about the time of holding Easter; and 'Five Books against Heresies.' A Latin translation of the last work is still extant; but all the rest have perished, with the exception of a few fragments.

IRETON, HENRY, the eldest son of German Ireton, of Attenton, in Nottinghamshire, was born in 1610. He was entered at Trinity College, Oxford, in 1626, and having taken the degree of bachelor of arts, became a student of the Middle Temple. He entered the parliamentary army, and made such a proficiency in the military art, that it has been asserted that Oliver Cromwell learned its rudiments from him. In 1646 he married Bridget, Cromwell's eldest daughter. He distinguished himself in the battle of Naseby, and was taken prisoner by the royalists, but made his escape. He attended most of the sittings of the regicide court, and signed the warrant for Charles' execution. On the establishment of the Commonwealth he was made president of Munster, and afterwards lord-deputy of Ireland. While in the height of his successes, he was seized before Limerick with the plague, of which he died on the 15th of November, 1651. He was buried in Henry the Seventh's chapel in Westminster Abbey; but the corpse was exhumed after the Restoration, gibbeted, and burned at Tyburn.

IRIARTE. [YRIARTE.]

IRIDA'CEÆ, a natural order of endogenous plants. The genera are numerous, and some not well defined; they inhabit the temperate parts of the world in preference to the hottest, where they are comparatively rare. The *Iris* and *Crocus* are representatives of the predominant northern form of the order, as *Gladiolus* and *Ixia* are of the genera prevalent in the southern hemisphere. All the species are sufficiently ornamental to deserve cultivation, and many are of striking beauty.

IRIDIUM, a metal discovered by Dr. Wollaston, and found combined with the ores of platinum, from which it may be separated by a complex chemical process. A few minute grains of native iridium have been met with.

Iridium is brittle, and when carefully polished, has the appearance of platinum. Specific gravity, about 18·6. When heated to redness in the air, if in a state of fine division (which is obtained by precipitation), it is oxidized, but not if in mass. Iridium is with difficulty acted upon by acids.

Oxygen and *Iridium* combine and form several oxides: the protoxide, sesquioxide, and teroxide. They are precipitated by the alkalies from the corresponding chlorides. The protoxide is black, and greenish gray when combined with water. The sesquioxide is also black, but its hydrate is deep brown. It is not decomposed by a low red heat. When slightly heated with charcoal, sulphur, or phosphorus, it detonates violently. Acids do not act upon it, but, on the contrary, it unites with salifiable bases. The teroxide is yellowish brown, or greenish in the state of hydrate.

Chlorine and *Iridium*.—The protochloride of iridium is insoluble in water, and is sparingly dissolved by acids or nascent chlorine. The sesquichloride has so dark a yellowish brown tint, that a small quantity renders water opaque. It yields by evaporation a dark-coloured, uncrystallizable, deliquescent mass. The bichloride has many of the external properties of the last-named compound.

Iridium combines with carbon when a piece of this metal is held in the flame of a spirit lamp. The resulting compound consists of about 19·8 of carbon, and 80·2 of iridium. The remaining compounds of iridium are very little known.

IRIS. [EYE; RAINBOW.]

IRIS, a genus of plants the type of the natural order *Iridaceæ*. *I. versicolor*, Blue Flag, is a native of swamps and wet meadows in the United States. The root-stock has a nauseous acid taste. It acts as a cathartic. *I. pseudacorus*, Yellow Flag, is a native of wet places in Great Britain, France, Germany, and most countries in Europe. *I. Florentina*, Florentine Iris, is a native of the southern parts of Europe and the islands of the Mediterranean. The root-stock, known by the name of *Orris-root*, has an aromatic odour and subacid taste, and is employed as a dentifrice. It was at one time used in medicine, and admitted into the British Pharmacopœias. The fresh root-stock acts as a purgative, and was also employed as an expectorant in diseases of the chest. When dried and turned into small balls, it is used for Issue-peas. Many species of *Iris* have been described. *I. Germanica* has been used for the same purposes as *I. Florentina*, and they are considered by some botanists to be identical. The roots of many

of them contain starch, and Pallas says that the roots of *I. dichomata* are eaten in Siberia. *I. edulis* is eaten by the Hottentots of Africa. All these species are cultivated in gardens on account of their handsome showy flowers.

IRISH LANGUAGE. [GAELIC.]

IRITIS is an inflammation of the iris, the membrane that surrounds the pupil of the eye. It most frequently originates in a disordered state of the system, as in gout or syphilis, but it sometimes follows the exposure of the eye to an intense light, or is produced by external injury, as the wound which is made in the operation for cataract, &c. This disease requires an active antiphlogistic treatment.

IRKUTSK. [SIBERIA.]

IRON (*Ferrum*, Latin; *Fer*, French; *Eisen*, German; *Ferro*, Italian), one of the most useful of the metals, and of the highest industrial value, is of a bluish-gray colour, but acquires lustre by polishing. It is fibrous in fracture, and of the ductile metals is the hardest and toughest. It cannot be hammered into very thin plates, but may be rolled out into sheets of astonishing thinness, or drawn into very fine wire.

The iron of commerce is seldom or never pure, but contains small portions of sulphur, carbon, silicium, phosphorus, arsenic, &c.; its density varies a little according to its purity and the method of its manufacture. Purified by fusion with smithy scales, it furnished in some experiments a specific gravity of 7.8439, which is increased by rolling and drawing into wire. Pure soft bar iron, with only a trace of carbon, has a density of 7.79; that of ordinary bar iron is 7.788.

When iron is subjected to a red heat it softens and becomes tough, a quality which increases its value in the manufacturing arts; and its faculty of welding, or uniting, at a white heat, renders it more easily workable than any other metal; when heated above the welding point it crumbles under the strokes of the hammer.

The point at which iron melts is variously estimated by different authorities. Mackenzie places it at 158° Wedgwood; Morveau at 175° Wedgwood, or 6436° Centigrade; and Daniell at 1587° Centigrade. As the metal when impure is more easily fused, this may account for the discrepancies in the foregoing statements, though they are sufficiently wide to enable us to appreciate the great difficulty of obtaining accurate measurements of very high temperatures.

Iron, as everybody knows, is attracted by the magnet, and is easily rendered magnetic; but it loses this property when converted into steel.

Historical Notice.—Whatever may have been the characteristics of the mythic age of gold, it is certain that man could only attain to a high degree of civilization in the age of iron; for without that metal, nations never rise out of the completest barbarism. Its possession by any people is equivalent to their advancement in all those arts and sciences which promote the happiness of the many, while leading to the enrichment of the few. It may be for this reason that, notwithstanding the obvious difficulties of its manufacture, iron is one of the earliest metals mentioned in history. We read in Genesis of Tubal Cain, the great-grandson of Cain, as ‘an instructor of every artificer in brass and iron.’ The

hills of Palestine produced ferruginous ore, and Job says that ‘iron is taken out of the earth.’ In the most ancient books of holy writ, reference is constantly made to weapons and implements fabricated from this valuable metal, and it is certain that iron furnaces were generally in use in Ancient Egypt. It is evident that the Pyramids, and similar colossal works, could never have been executed without the assistance of iron tools.

We gather from Homer some idea of the value which the Greeks of his era set upon the metal, for a mass of iron is one of the prizes at the funeral games which Achilles celebrated in honour of Patroclus:—

Then hurl'd the hero, thundering on the ground,
A mass of iron—an enormous round—
Whose weight and size the circling Greeks admire,
Rude from the furnace, and but shap'd by fire.
. Who furthest hurls it, takes it as his prize.
If he be one enriched with large domain
Of downs for flocks, and arable for grain,
Small stock of iron needs that man provide;
His hinds and swains whole years shall be supplied
From hence; nor ask the neighbouring city's aid
For ploughshares, wheels, and all the rural trade.
(Pope's Translation.)

The iron which is here spoken of, and in other passages of Homer and Hesiod, was an imperfectly malleable metal wrought at once from the ores in the furnace. The ore was probably obtained through the Phenicians—those navigators and carriers of the ancient world, who in so many respects were the prototypes of our own nation—from Laconia and the shores of the Black Sea. Diodorus Siculus refers to the isle of Elba as furnishing the ore of this metal, which the natives dug out of the ground, and subsequently melted to obtain the metal. Pliny, in his ‘Natural History,’ describes its manufacture at considerable length, and the various uses to which it was applied. It should be noted, however, that though the Latin writers apply the word *ferrum* (iron) to a sword, the weapons and cutting instruments discovered among the ruins of Pompeii and Herculaneum are almost invariably found of bronze.

Nothing, perhaps, is more remarkable in the history of the iron manufacture than the slowness with which it was developed in England. Iron was mined and smelted in our island in the time of the Romans, but for some centuries afterwards our English mines were left wholly unworked; and so precious was the metal esteemed, that Edward III. included the pots and pans of the royal kitchen among his majesty's jewels. The Spaniards, in designing the Armada, calculated on the superior excellence and abundance of Spanish iron compared with English as an important element of success. In the fourteenth and fifteenth centuries we were supplied with iron and steel from Spain and Germany; while, as late as the middle of the eighteenth century, we imported from Sweden no less than four-fifths of the iron used in this country.

This neglect of what is now one of the principal sources of our national wealth was owing to the enormous consumption of timber as fuel rendered necessary by the old smelting processes. The charcoal required to produce a single ton of pig iron represented four loads of wood, and for a ton of bar iron, seven loads of wood. The iron manufacture, then, was confined to the counties of Kent, Surrey, and Sussex—that is, to the neighbourhood of the Weald, or ‘wooded

country,' and it threatened to sweep away the forests which were once its glory and its wealth. This destruction of timber attracted attention as early as the sixteenth century, and both Henry VIII. and Elizabeth attempted to check it by legislative provisions. John Norton, in his 'Surveyor's Dialogue,' (1607) asserts that Sussex alone contained nearly 140 hammers and furnaces for iron, each of which consumed every twenty-four hours from two to six loads of charcoal. Drayton, in his 'Polyolbion,' grievously bewails the disappearance of thick embowering woods and leafy groves:—

These forests, as I say, the daughters of the Weald
(That in their heavy breasts had long their griefs
concealed),
Foreseeing their decay each hour so fast come on,
Under the axe's stroke, fetched many a grievous groan,
When as the anvil's weight, and hammer's dreadful
sound,
Even rent the hollow woods and shook the queachy
ground;
So that the trembling nymphs, oppressed through ghastly
fear,
Run madding to the downs, with loose dishevelled hair.

The Sussex iron varied in quality. 'Some,' says Camden, 'was more brittle than the Spanish iron; but that worked in the neighbourhood of Ashburnham is said to have been equal to the Swedish metal, generally accounted the best in the world.'

The first iron cannon ever produced in England was cast at Buxted, in Sussex, by Ralph Hoge or Hogge, in 1543.

From the time of the civil war the iron manufacture of Sussex, as of England generally, declined very rapidly. In 1740, only fifty iron furnaces existed in all England, of which ten were in Sussex; and in 1788, there were only two. A few years later, and the Sussex iron furnaces were altogether extinguished. The din of the iron hammer was silenced, and the glare of the furnace had faded. Some of the furnace ponds were drained, and planted with hops or willows; others were converted into beautiful lakes in sequestered pleasure grounds; and the remainder were employed to drive flour mills, as the streams in Kent, once used to drive fulling mills, were diverted to work paper mills.

The rise of the English iron manufacture, as a staple of national wealth, dates from the employment of coal in the smelting operations. The first who attempted it was a German, named Simon Strutevant; but his process, theoretically correct, proved a failure in application. Dod Dudley, an enterprising Worcestershire iron master, was more successful, and in February, 1620, applied for a patent for his invention, which was granted for thirty-one years. In due time the process was introduced by a quaker, named Abraham Darby, at the celebrated Colebrookdale Works, in the valley of the Severn. It was a grandson of this ingenious person who designed and erected the first iron bridge in England.

The change from charcoal to coke as fuel necessitated a more powerful blast, and a longer subjection of the materials to the heat. The latter was effected by enlarging the height of the furnace, and the former by substituting for the common forge bellows large cylinders with closely fitting pistons. The earliest blowing cylinders of any magnitude were erected by the celebrated Smeaton at the Carron Ironworks in

1760. These improvements produced an astonishing increase in the quantity of iron manufactured. Dr. Ure supplies the following figures as representing the quantity of cast iron produced in 1788:—

	Tons.
By means of coal, ...	48,800
By means of charcoal, ...	13,100
Total, ...	61,900

In 1806 there existed 227 blast furnaces in this country, 159 of which were in active blast at once, and yielded 250,000 tons of iron.

The blast furnaces were distributed as follows:—

In Wales, ...	52
Staffordshire, ...	42
Shropshire, ...	42
Derbyshire, ...	17
Yorkshire, ...	28
The counties of Monmouth, Gloucester, Leicester, Lancaster, Cumberland, and Northumberland, ...	18
Scotland, ...	28
Total, ...	227

Nearly contemporaneous with the earliest improvements in the manufacture of cast iron by means of pit coal, were others of an equally important kind for the conversion of cast iron into malleable or bar iron. In 1783 Mr. Richard Cort—one of the most illustrious names in the history of the iron manufacture—succeeded in converting cast iron into malleable iron by the employment of pit coal in a reverberatory, instead of a blast furnace, and thus introduced what is known as the *puddling process*. Notwithstanding its great value, Mr. Cort met with the common fate of inventors, and derived but little benefit from his ingenuity; and it was not until a few years ago that a pension of 50*l.* per annum was granted by government to the widow of the man who had contributed so largely to the national wealth.

The general introduction of the steam-engine, as improved by Watt, also gave a great impetus to the development of the iron manufacture. It enabled mines to be sunk to a greater depth, and facilitated the process of raising the coal and ore, while its employment as a motive power effected astonishing changes, of which it is unnecessary in these pages to speak in detail.

Finally, the hot-blast process, invented by Mr. Neilson, of Glasgow, in 1824, which produces nearly four times the quantity of iron with little more than one-third of the fuel required by the cold blast; and Bessemer's refining process, which materially facilitated the conversion of iron into steel, mark two great eras in the history of this important and valuable metal.

Ores of Iron.—We now proceed to a brief examination of the various sources from which iron is obtained:—

Native Iron was for a long time unknown, and even its existence doubted; but nevertheless it has been found in several localities, both on the continent of Europe and in America. In this country it has been discovered in minute quantities in trappean

rocks, but invariably in such small fragments that it can only be regarded as a mineralogical curiosity. Native iron is almost pure white, more resembling silver than ordinary iron, is generally softer and less dense, and, unlike meteoric iron, contains no nickel. A mass was found at Gross Ramsdorf in Thuringia, which, according to Klaproth, yielded the following constituents:—Iron, 92·5 + lead, 6·0 + copper, 1·5 = 100 parts.

In Siberia it is found in considerable quantities; and as it is soft and flexible, and easily cut with a chisel, the natives use it for implements. It contains 98·48 parts of iron, and 1·60 of silica.

Meteoric Iron.—Nothing is certainly known of the history and origin of those large masses of iron found in localities where no ferruginous strata exist, but they are generally supposed to have fallen from the atmosphere, and, accordingly, are designated *meteorites*. They are generally covered with a kind of black enamel, which protects the metal from the atmospheric action, and the iron usually forms a species of network round a crystallized metallic mineral, containing various ingredients, such as iron, nickel, cobalt, copper and tin, manganese, phosphorus, silica, alumina, potassium, magnesia, soda, carbon, sulphur, chlorine, etc.

Oxydulous or Magnetic Iron.—This is formed by a combination of the protoxide with the sesquioxide of the metal; has a black colour, and is hard, crystalline, and arenaceous. It exists abundantly in different rocks—in granite, hornblende, mica-slate, clay-slate, syenite, chlorite, and most of the limestone formations. Almost all the Swedish iron is manufactured from this compound, which also abounds in the United States of America. Its density varies from 5·00 to 5·10, and its chemical composition is as follows:—

$\text{Fe}_3 \text{O}_4$, or $\text{Fe}_2 \text{O}_3 + \text{Fe O}$.	
3 Eqs. Iron, ...	71·68
4 Eqs. Oxygen, ...	28·32
	100·00

Oligiste Iron; Specular or Micaceous Iron; Red Hematite.—Occurs in masses, and crystalline. The crystals are attached; the primary form is a rhomboid; colour, a bluish-gray, with slightly iridescent surface.

Bog Iron Ore is amorphous, with a vitreous lustre, and a yellowish or dark-brown colour; belongs to very recent formations, and appears to arise from the decomposition of certain rocks by running water. Hence it derives its name from being always found in low, marshy localities. It consists of sesquioxide of iron, water and organic matters, and of protoxide of iron, lime and magnesia, oxide of manganese, phosphoric acid, silica, and alumina, in varying quantities.

Iron Pyrites occur in many forms, but always consist of combinations of iron and sulphur. They vary in tint according to their exposure, from a yellow bronze to a silver white. Their crystals are beautiful cubical and octahedral figures. Arsenical iron pyrites, or *mispickel*, is found abundantly in Cornwall and on the Continent, and frequently associated with other metals, such as tin. When struck by a hammer, or rubbed on any hard or heated

surface, it emits a strong garlic-like smell. Its constituents are as follows:—

Iron (two equal parts of), . . .	33·54
Sulphur, ...	19·87
Arsenic, ...	46·59
	100·00

Carbonate of Iron is the most common of the British ores, and most of the British iron is manufactured from it. They chiefly consist of a carbonate found in beds in the coal formation, frequently alternating with the seams from which the coal is taken. These deposits in Britain occur at Dudley, in England, in Lanarkshire and Ayrshire, in Scotland, and in Wales. Of these ores we note two principal varieties:—First, the argillaceous or clay-band, which, as they contain a large admixture of earthy matter or clay, yield, when wrought alone, a weak and inferior kind of iron. They present a dark gray colour, nearly black, and their specific gravity varies from 3·17 to 3·41. We subjoin analyses of specimens procured in different districts:—

Protoxide of iron, .	32·22	38·80	35·0
Carbonic acid, .	32·53	30·76	25·5
Manganese, . . .	—	0·07	0·3
Lime, ...	8·62	5·30	—
Magnesia, . . .	5·19	6·70	1·6
Silica, ...	9·56	10·87	26·5
Alumina, ...	5·34	6·20	11·8
Sesquioxide of iron, .	1·16	0·33	—
Carbon, ...	2·13	1·87	—
Sulphur, ...	0·62	0·16	—
Loss, ...	2·63	—	—
	100·00	101·06	100·7

The second variety of this ore, black-band, was for a long time unknown, and was first pointed out by the late D. Mushet. It contains less earthy matter than the clay-band, and is much blacker in appearance. The difference will best be understood by a reference to the following analyses:—

Protoxide of iron, .	49·4	49·6	46·6
Carbonic acid, . .	35·2	30·4	30·1
Magnesia, ...	4·0	8·1	—
Alumina, ...	1·8	1·3	—
Lime, ...	—	—	6·3
Silica, ...	—	—	5·4
Coaly material, . .	9·6	9·6	8·4
Loss, ...	—	0·5	3·2
	100·0	100·0	100·0

Iron Froth consists of very thin, brownish-red, scaly particles, which stain the fingers, and have a saponaceous feel. The massive varieties are amorphous; the structure foliated.

Hydrous Oxide of Iron; Brown Iron Ore; Brown Hematite.—Occurs in aggregated crystals and massive prisms. Primary form a right rhombic prism; colour brownish. The massive varieties are globular and reniform; some of the varieties constitute brown clay ironstone.

Among the artificial oxides and other compounds of iron procured by chemical agency, we may name the following:—

Oxygen and iron combine to produce three or four bodies. The *protoxide* ($O^1 I^1$) is tasteless, black, insoluble in water, readily dissolved by most acids, and easily affected by the magnet. The *magnetic oxide* ($O^4 I^3$) is also black, obeys the magnet, brittle, easily reduced to powder, and in water insoluble. The *peroxide* or *sesquioxide* ($O^3 I^2$) constitutes the common rust of iron; colour red, is inodorous, tasteless, insoluble in water, and forms red solutions with acids.

Chlorine and iron combine to form two chlorides. The *protochloride* ($Ch^1 I^1$) is a gray crystalline substance; easily soluble in water, but insoluble in absolute alcohol. The *perchloride* ($Ch^3 I^2$) appears as brownish iridescent scales, very deliquescent. The aqueous solution is readily decomposable.

Fluorine and iron form the *protofluoride* ($F^1 I^1$), in small, square, colourless crystals; and the *perfluoride* ($F^3 I^2$), a pale, astringent, flesh-coloured substance.

Bromine and iron unite to form a yellow fusible bromide ($Br^1 I^1$), readily soluble.

The result of combined carbon and iron is steel; or, in other words, steel contains *carburet of iron*. *Sulphur* and iron also unite very readily; and the native compounds are among the ores already described. *Protosulphuret* ($S^1 I^1$) resembles in appearance the native mineral; the *bisulphuret* forms a yellow crystal or yellow powder, according to its mode of preparation.

Diphosphuret of Iron, a brittle, fused, granular mass ($P^1 I^2$), is a compound of *phosphorus* and iron; so, also, is the *perphosphuret* ($P^4 I^3$).

Iodine and iron combine to form a *protiodide* ($Iod^1 I^1$), an iron-gray coloured opaque mass, very deliquescent, and soluble both in water and alcohol. It is used in medicine. The *periodide* ($Iod^3 I^2$) is a red, volatile, deliquescent compound.

The Alloys of Iron.—These are much less useful than might be expected from the extreme usefulness of the metal itself.

Potassium and iron, and *sodium* and iron, combine when heat is applied to them: the alloys are more fusible than pure iron, especially when in contact with the air. These alloys are decomposed by air and water. *Silicium* and iron form an alloy which is ductile or brittle according to the quantity of charcoal which it contains. *Arsenic* and iron form an alloy which has a grayish-white colour, does not obey the magnet, is very brittle, and much more fusible than iron. Other alloys with arsenic may be formed. *Chromium* and iron form an alloy very little known. With *columbium* a hard brown alloy is formed. *Zinc* gives a white and brittle alloy with iron. *Tin* and iron form the alloy seen on tin-plate ware. *Antimony* and iron unite when heated together in close vessels: the alloy is white, hard, brittle, and its specific gravity is less than that of the mean of the two metals. No metal appears to deprive iron more of its magnetic property than antimony. *Cobalt* and iron form a hard magnetic alloy. *Nickel* and iron form the meteoric alloy. *Bismuth* combines with difficulty with iron. *Molybdenum* forms with it a bluish-gray brittle alloy. The alloy of *copper* and iron is magnetic. *Silver* combines readily with iron when they are fused together, but they separate on solidification, and globules of

silver appear on the surface of the alloy. With *Mercury* a white tenacious alloy is formed. *Lead* and iron combine with difficulty. *Rhodium*, *iridium*, *tungsten*, and *platinum* may all be made to form alloys with iron. *Gold* and iron combine with facility. A compound of eleven parts of gold and one part of iron is nearly white. It is very ductile, and its specific gravity 16.885. An alloy of three parts of iron and one part of gold is of a silver colour, and is attracted by the magnet.

The action of acids upon iron differs, being greatly dependent upon their nature and composition, and upon their temperature at the time of contact.

Sulphate of Iron, or *Sulphate of Protoxide of Iron*, is largely made use of for various purposes, especially for dyeing black. It is generally known as *copperas*, or green vitriol. The primary form of the crystal is an oblique rhombic prism; its colour, bluish-green when recently prepared; but by exposure to the air, and the partial peroxidization of the iron, it changes to green, and then to a dull yellow. Like the other salts of iron, it has a disagreeable styptic taste. The sulphate of peroxide of iron represents the soluble salts of peroxide of this metal. When concentrated, its colour is reddish; when diluted, yellowish. No crystals are yielded by evaporation, but a brown deliquescent mass is deposited; its taste is very astringent, and it dissolves in alcohol.

There are two *Nitrates of Iron*: a pale green protonitrate results from the action of very dilute nitric acid, and pernitrate when the acid is very moderately diluted.

Carbonate of Iron is the protoxide combined with carbonic acid so as to form a solid. It is the basis of what is termed the argillaceous iron ore, and sometimes occurs pure in transparent rhombic crystals.

Phosphate of Iron.—The *protophosphate* occurs in Cornwall, America, &c., as a greenish, oblique, rhombic, prismatic crystal; it may also be prepared artificially as a blue precipitate. The *perphosphate* is white; it is obtained by adding phosphate of soda to persulphate of iron. Like the protophosphate, acids, but not water, will dissolve it, and from them it may be precipitated unaltered.

Arsenates of Iron.—The *proto-arseniate* is a grayish precipitate, which, upon exposure to the atmosphere, absorbs oxygen and becomes darker. The *perarseniate* is a pale yellow powder, insoluble.

Chromate of Iron. [CHROMIUM.]

Iron Manufacture and Trade.—This metal is usually divided into two distinct qualities—pig iron and malleable or bar iron—the second resulting from an extension of the processes necessary for the production of the first.

The first process is that of reducing the ironstone ore, or, as it is technically called, the *mine*, into a metallic state by means of fusion. This operation is conducted in a blast or smelting furnace. (See Plate 1, 'Iron Manufacture'.)

The most modern kind of blast furnace may be exemplified by reference to the works recently erected at Ulverstone by Messrs. Schneider and Hannay. Here the waste gases are drawn off by a tube descending several feet into the furnace, where it is supported on arms of brick. The diameter of the tube is about one-third that of the furnace-mouth.

The gases are led away in this manner to admit of the charges of ore, fuel, and limestone being equally distributed, so as to equalize the working of the furnace. Large fans, to assist in drawing them off, are placed in connection with the flues, which receive the products of their combustion in the stoves and under the boilers. Thus, to a great extent, the loss formerly caused by the 'waste gases' is prevented.

The furnace, thus arranged, is charged from the top with certain proportions of iron-ore, coke, and limestone; the ore having been previously roasted in a kiln, in order to drive off its admixture of water, sulphur, and arsenic—a process by which it loses one-sixth part of its weight.

A furnace of the size commonly employed will produce from five to six tons of pig iron in twelve hours, though the improved blast-furnace already referred to yielded 1279 tons in fourteen days. For six tons the furnace must be charged progressively with 15 tons of roasted iron-ore, $2\frac{1}{2}$ tons of coke, and about 6 tons of limestone. But the exact proportions of the materials put into the blast furnace differ in every locality, and with every charge of ore or coal. The ingredients are supplied at fifty charges, and must be closely mixed together in the furnace. Some smelters break up the limestone into small pieces of the size used for macadamizing roads; others think it unnecessary, as the limestone, when thrown into the furnace, very soon flies to pieces by the heat. Its use is to act as a flux to the ore, and promote fusion.

Turan thus describes the action of the furnace: The changes which occur in the descending ore commence with the uncalcined ores in the throat of the furnace; they lose their moisture and volatile gases before they reach the level of the boshes, absorbing from the fuel the necessary caloric for calcination. Below this the ore is gradually converted from a sesquioxide to a magnetic oxide, or, as sometimes occurs, into metallic iron; having combined with a portion of the carbon from the fuel, to form the fusible carbide of iron. From the bottom of the boshes to the level of the tuyeres, the reduction of the ore and flux into a liquid mass is completed. The fusion of the ore and flux occurs at a height of eight or ten inches above the tuyere, from whence it descends into the hearth. Here the metal, from its greater specific gravity, drops to the bottom, freed more or less from the fluid cinder which floats on the surface, and protects it from the oxidizing influence of the blast.

As soon as the ore is properly fused, a tap-hole is opened in the crucible or hearth, and the molten metal is allowed to run out every twelve hours into channels grooved in the sand of the smelting-house floor. The iron in this form is called *pig iron*, and in Britain its produce averages about 60 per cent. The term was given by the workmen; the metal being run off from the furnace in a main channel, which they call the *sow*, and the bars at right angles to it, like *pigs* attached to their mother's teats. The quality of this product depends upon the nature of the ore and fuel employed, but it is usually divided into *founndry iron* and *forge iron*, the former adapted for castings, and the latter for malleable purposes. Cast iron is further divided into five classes:—

No. 1 is the best gray, possesses the greatest

quantity of carbon, and melts at a lower degree of heat than any of the others; it sets with a smooth surface, is soft, and has little sound when struck by the hammer.

No. 2 is lighter in the colour than No. 1; not so soft nor so fluid when melted, nor so smooth on the surface when solidified; it is closer in the texture, and is preferable for strong parts of machinery.

No. 3 has less carbon than the other two, and is still less fluid when melted; has smaller grains, and is smoother in the fracture. This is used for very strong machinery where it is subjected to great and sudden strains, such as heavy shafts, wheels, and the like.

No. 4 is not so much used in foundry work; it is lighter in colour and harder than No. 3, but is with difficulty distinguished from it.

No. 5, or what is termed white iron—sometimes silver iron—is rarely employed in the foundry; it is very brittle, and does not run into the moulds, being difficult to keep in a state of fusion.

Manufacture of Malleable Iron.—Before pig iron can be converted into malleable or bar iron, it must undergo a refining operation, and be purified from the foreign matters which more or less affect its natural properties of malleability and ductility. This refining process is performed in peculiarly constructed furnaces, called *refineries* or *running-out fires*, which are composed of a body of brickwork, about nine feet square, rising but little above the ground. In the centre is placed the rectangular-shaped hearth, about three feet by two, and thirty inches deep; it is formed by the junction of four cast-iron troughs, through which is poured a continual stream of cold water to prevent them from being fused by the heat.

The operation begins by filling the hearth or crucible portion of the furnace with coke; upon this are laid six pigs of iron from the blast furnace, and more coke is heaped upon them. The fire is kindled at bottom; after a while the blast is let on, and, as the heat increases, the iron melts and flows to the bottom; more coke is added as it burns away, to preserve the metal in a state of fusion. During this operation the iron expands, heaves up, and evolves oxide of carbon. In the course of two hours the metal is tapped out into pits or beds, forming large plates, on which quantities of water are poured to render them brittle. The metal thus treated is very white, and, owing to its rapid cooling, generally possesses a fibrous radiated texture; it is also full of cells from the escaping of gaseous matters. A heavy black scoria, principally composed of silicate of iron and other impurities, is produced in this operation. When the quality of the iron is very inferior, a small portion of lime is added to the fire to take up the earthy matters, and in this case the scoria will contain lime. As already remarked, in fusing iron in the cupola the earthy matter in the coke requires to be combined with a little lime; otherwise, if present in any quantity, it will take away much of the iron. In some places the iron is run into these refining furnaces directly from the blast furnace, a method which saves the time and fuel required to remelt the pigs, but is also attended with certain disadvantages which have prevented its general adoption.

The change effected upon the iron in this operation is the oxidation and consequent dispersion of a great

portion of the impurities. The following are Dr. Muspratt's analyses of the results:—

	Iron before refining.	Same iron after refining.
Iron, ...	95·26	98·33
Carbon, ...	2·63	·87
Silicium, ...	1·38	·53
Aluminium, ...	·73	·26
Phosphorus, ...	trace	trace
Sulphur, ...	trace	trace
	100·00	99·99

Puddling.—The next process of refining is termed puddling, and is performed in a reverberatory furnace. [FURNACE.] From three and a half to four hundredweight is put in at once, in pieces laid one upon another on the sides of the hearth, leaving the central part free for the puddler's operations. The furnace is then closed up, and the fire kindled to a white heat; in about twenty minutes the metal begins to melt, and falls off in drops upon the hearth or sole of the furnace. The furnace-man, by means of a paddle, removes the iron from the hottest parts to prevent its melting too rapidly. When all the metal is reduced to a pasty state, the temperature of the furnace is lowered that it may not become more fluid. The furnace-man then works about the pasty metal with his paddle, during which it expands with the discharge of gaseous matters. As this continues, the metal as it gets finer becomes less fusible; the gases no longer escape; and by the constant puddling or kneading with the paddle, it becomes reduced to a

sort of sandy consistence. During these operations, small quantities of water are thrown into the furnace. At this stage the heat is increased; the metallic particles again cohere, and grow what the workmen call *heavy*. The furnace-man, with his paddle, gathers a lump of metal on the end of it, as a kernel, and rolls it to and fro on the surface of the clotted mass until he collects a ball of about seventy pounds in weight. This is placed on the side of the hearth at the hottest part, and, with a rake or paddle, termed a *dolly*, is squeezed as forcibly as possible to drive out any scoria. When the whole of the metal is thus gathered into balls, the furnace heat is again intensified to facilitate the welding. The balls are then lifted out; by means of tongs, if roughing rollers are to be used, or with an iron rod, welded to the ball, if it is to be subjected to the action of the hammer.

The time occupied in puddling a charge is from two to two and a half hours. The loss of iron in this process varies considerably, both according to its quality and the skill of the workman. On an average the loss is about 10 per cent. During this operation, a considerable quantity of scoria, which exudes from the metal, runs off from the hearth and is removed. The component parts of this scoria scarcely differ from those of the scoria produced in the refining furnace, except that a quantity of the iron is found in the state of sesquioxide.

We borrow from Dr. Muspratt the following analyses of refined or malleable irons of different qualities, and from various localities, exhibiting the extent of the effects produced by refining, when compared with the composition of crude iron:—

	Iron.	Carbon	Phosphorus.	Silica.	Arsenic.	Copper.	Manganese.

Rolling the Iron.—After the balls of iron, or *blooms*, have been removed from the puddling furnace, and subjected to ten or twenty blows from a heavy hammer, called *shingling*, they are passed through the rollers. The hammer now in use was invented by Mr. Condie, of the Govan Iron Works, near Glasgow, about 1846. It weighs from forty to fifty cwt. The rollers may be roughly described as consisting of two cylinders worked in contact, and having on their surfaces a series of grooves, varying in size. Through these grooves the iron is successively passed, until reduced to the requisite width and thickness, water playing upon each pair of rollers in order to keep them cool. It has now been converted into a tough and elastic bar, which is readily fusible, and which, from its property of changing its form under the hammer, has acquired the name of malleable iron.

Sheet iron is made by passing the metal between smooth rollers, without grooves, the rollers being gradually screwed nearer together as the requisite thickness is being approximated to.

The speed of the different kinds of rolling-mills varies according to the character of their work. Those for merchant bars make from sixty to seventy

revolutions a minute, while those of large size for boiler plates are reduced to twenty-eight or thirty. Others, such as the finishing rollers, in which the shape and size of the bars are finally determined, run at from one hundred and twenty to four hundred revolutions a minute. (See Plate 1, 'Iron Manufacture'.)

Conversion of Iron into Steel.—*Bessemer's Process.*—The process by which Bessemer converts iron into steel is of recent date, and has justly been characterized as one of the grandest instances of progress in manufactures which has been made of late years. To insure its successful operation, however, it is necessary to employ pig iron as free as possible from sulphur and phosphorus. The following are the principal details:—

The crude pig iron having been melted in a reverberatory furnace is run into what is called the *converting vessel*, A (see Plate 2, 'Iron Manufacture,' figs. 9 and 7), for the purpose of undergoing its transformation into steel. The converting vessel is shown, enlarged in section, in fig. 2; the melted pig iron being run into it direct from the furnace. It is made of stout boiler plate, and lined with a powdered silicious stone, found in the vicinity of

Sheffield, below the coal, and locally known as 'gannister.' The converting vessel, A, is mounted on bearings, which rest on stout iron standards, C C, and by means of the gearing and handle, D, it may be turned into any required position. An opening is made at the top for filling and pouring out the metal, and at the bottom of the vessel are inserted seven fire-clay tuyeres, each with seven holes as shown in the Plate, fig. 1, and in the enlarged longitudinal and horizontal section of one of the tuyeres, fig. 3. The blast from the engine is conveyed through one of the bearings, E, of the vessel, fig. 7, into the tuyere-box, F, and enters the tuyeres at a pressure of 14 lbs. per square inch, which is more than adequate to prevent the vessel from entering therein.

Before commencing with the first charge of metal, the vessel's interior is thoroughly heated by coke, with a blast through the tuyeres to stimulate the fire; when sufficiently heated, it is inverted, and all the unburnt coke falls out. The vessel is then placed horizontally, and the melted pig iron run into it from the furnace by the spout, the vessel being so held during the operation that the holes of the tuyeres are above the surface of the metal. When the proper charge of iron has been run in, the blast is turned on, and the vessel quickly moved up into the position shown in fig. 2. The blast now rushes up from each of the forty-nine tuyere holes into the fluid metal, producing a most violent agitation of the whole mass. The silicium, always present in greater or less quantities of pig iron, is first attacked, and unites readily with the oxygen of the air, producing silicic acid; a small portion of the iron simultaneously undergoes oxidation, and hence a fluid silicate of the oxide of iron is formed, a little carbon being simultaneously burnt off. Thus the heat is gradually increased, until nearly the whole of the silicium is oxidized, which usually occurs in about twelve minutes from the commencement of the process. A most intense combustion rapidly takes place; the metal rises higher and higher in the vessel, sometimes occupying more than double its former space, and in its frothy fluid condition presenting an enormous surface to the atmospheric action, until the whole mass glows like flame, and presents a perfect combination of metal and fire. The carbon is now burnt off so rapidly as to produce a series of innocuous explosions, throwing out the fluid slag in great quantities, while the combustion of the gases is so complete that a volume of white flame rushes from the vessel's mouth, illuminating the entire building, and indicating to the skilful eye the precise condition of the metal inside. A little charcoal pig iron is now added, the blast turned on for a few seconds, and the process, which altogether occupies about twenty minutes, is complete.

The vessel, A, is then turned into the position shown in fig. 4, and the fluid steel run into the casting-ladle, B, which is carried by the hydraulic crane, H, being counterbalanced by the weight, I, on the opposite end of the jib, as shown in fig. 9. When all the metal is poured out of the converting vessel, the crane is raised by water pressure, and turned round, as shown in fig. 5, for the purpose of running the steel into the ingot moulds, K. Instead of tilting the casting-ladle for pouring into the

moulds, it is made with a hole in the bottom fitted with a fire-clay seating, L (fig. 6), and closed by a conical fire-clay plug, forming a conical valve. The valve-rod, N, is coated with loam, and bent over at the top, and works in guides on the outside of the ladle, as shown in fig. 8, with a handle, O, for opening and closing the valve. By thus tapping the metal from below, no floating impurities can pass into the mould, and the current of fluid steel pours down the centre of the mould without coming in contact with its sides. The different moulds, which are of a slightly tapered form, are arranged in the pit in an arc of the circle described by the casting-ladle, as shown in the plan, fig. 1.

By this ingenious process, which has proved of the greatest utility to our manufacturers, from one to ten tons of crude iron may be converted into cast steel in thirty minutes, without manipulation, and without employing any other fuel than is required for melting the pig iron, and for the preliminary heating of the converting vessel. The loss in working English iron in small quantities is from 14 to 18 per cent., but with pure Swedish iron does not exceed $8\frac{3}{4}$ per cent.

Trade in Iron.—From the *Mercantile Gazette* we extract the following remarks on the present condition and future prospects of this important trade:—

'The great advance in the value of iron in 1865 forms an important feature in our commercial history. Production has increased, the demand for home use and export has been somewhat active, and even a 7 per cent. bank rate has not prevented Scotch pig iron from advancing to 65s. per ton. This quotation, which shows an improvement on the year of 15s. per ton, is well supported, and some of the makers are sanguine that it will shortly be exceeded. The large quantity of iron now raised, and the dearness of money, must, we apprehend, check heavy speculative investments, and compel not a few of the masters to sell at prices which cannot be otherwise than remunerative. In England the transactions in metals generally have been extensive. The quotations have, consequently, steadily improved, although the importations from abroad have been on a liberal scale. That the consumption of metals generally in America is increasing, is evident from the rapid extension of the railroad system, as well as from the steady progress of trade generally. The necessity for larger imports, therefore, is obvious; and had it not been for the high duties levied upon foreign manufactured articles in the States, last year's shipments from the United Kingdom would have been considerably in excess of 1864, apart from the necessities of war. We have, however, done a good business as a whole, and the new year has opened with very good prospects for the trade generally. The value of metals in the United States is unusually high; there is no accumulation of stock either here or abroad; and the present rates ruling for most descriptions of iron are such as to insure considerable activity in the mining districts. There is, in point of fact, only one drawback to great activity—viz., a 7 per cent. rate for money. But then it may be said that we are likely to suffer from undue competition on the Continent from home makers of iron; that we cannot possibly sell at continental rates; and, further, that every effort will be made to exclude us from a fair partici-

pation of profit. Last year the total quantity of metal purchased in England on account of French houses was much larger than in 1864. The increased make in Belgium, however, and the unusually low prices ruling in that country, reduced our shipments of railroad iron from 6699 tons in 1863, and 1946 tons in 1864, to 786 tons in 1865. Russia was a large customer for iron last year. Of railway parcels she took 39,421; of castings, 11,897; of hoops, 5240; and of wrought, 7757 tons. Upwards of 25,000 tons of wrought iron were forwarded to India last year. To the same quarter nearly 100,000 tons of railway iron were shipped. The gradual extension of the railway system in India and Russia, and the trifling quantity produced in the latter country, must long continue to have an important bearing upon the trade in the United Kingdom.

We have already alluded to the trade in iron as one of the principal sources of our national wealth. The produce in Great Britain, in 1740, was estimated at 17,350 tons; in 1840, it had risen to 1,400,000 tons; and in 1865, to nearly 5,000,000.

The extension of iron manufacture, and the development of iron ore producing districts in Great Britain, is shown every year in the returns. In 1864 there were obtained 10,064,890 tons of iron ore. This was employed to feed 612 blast furnaces, which produced 4,767,951 tons of pig iron. The quantities produced in the years 1860-64 were as follows:—

	Tons.
1860, ...	3,826,752
1861, ...	3,712,390
1862, ...	3,943,469
1863, ...	4,510,040
1864, ...	4,767,951

When to this is added the immense quantities of iron in various stages of manufacture, which are annually imported into the United Kingdom, and the still greater quantities exported thence, some idea will be gained of the vast importance of the iron trade and manufacture of this country. The following table gives the weight and value of the different kinds of iron imported into the United Kingdom in 1864:—

Iron.	Tons.	£
Ore, ...	74,163	57,424
Pig, ...	20,126	120,756
Chromate of, ...	12,325	49,082
Unwrought, in bars, ...	53,918	625,283
Steel, unwrought, ...	7,619	124,066
Sheet, ...	2,442	28,600
Wire, ...	1,716	39,470
Rough Castings, ...	7	91
Bloom, ...	2,501	22,509
Slit into rods, ...	98	875
Cast, ...	1,349	16,188
Hoops, ...	117	1,847
Old broken, ...	13,635	40,905
Manufactures, ...	10,117	332,876

Total, ... 200,133 1,459,472

Iron ore is principally imported from Spain and France, pig iron from Sweden and Belgium, chromate of iron from Russia, bar iron from Sweden, and manufactured articles from Holland, Belgium, and France.

The following table gives the weight and value of

the various descriptions of iron and iron manufactures exported from the United Kingdom in 1864:—

Iron.	Tons.	£
Ore, ...	1,310	2,096
Pig and Puddled, ...	465,985	1,412,352
Bar (British), except railroad, ...	248,573	2,250,040
Bar (foreign), ...	12,881	149,366
Angle, ...	2,926	33,853
Railroad—rails and chairs, ...	384,042	2,852,966
“ wheels and axles, ...	8,428	179,711
“ other kinds, ...	15,745	272,409
Bolt and rod, ...	28,259	284,156
Castings, ...	64,183	575,528
Galvanized (not wire), ...	23,100	601,613
Hollow ware, ...	4,694	94,583

Articles of cast and wrought iron, ...	2,343	44,005
Other sorts (not ordnance), ...	47,748	1,039,004
Old, for re-manufacture, ...	3,494	13,818
Steel, cast in ingots, ...	529	18,016
“ bar of all kinds, ...	23,722	779,389
“ sheets, ...	2,583	92,990
Manufactures of steel and iron, ...	5,825	445,676
Iron and steel, un- wrought (foreign), ...	2,151	35,025
Iron and steel, wrought or manufactured (foreign), ...	22,946	47,704

Total, ... 1,548,077 13,990,351

Note.—The above table does not include steam-engines, machinery, and telegraphic wire; the imports and exports of which will be found under MACHINERY and TELEGRAPH.

To specify the markets for all these goods would be a waste of time and space, as they include nearly every country. We can only mention the most important, viz.:—Australia, British North America, United States, East Indies, and France, for pig and bar iron; the East Indies, United States, Argentine Confederation, Naples, Spain, and Russia, for railroad iron; and Australia, British North America, South Africa, East Indies, and British colonies generally, the United States, Russia, Denmark, Holland, Belgium, France, Egypt, and Brazil, for other kinds.

In 1865 the exports of pig and puddled iron had increased to 543,018 tons; bar, angle, bolt, and rod, 256,823 tons; railroad, 431,910 tons; wire, 24,037 tons; castings, 88,968 tons; hoops, sheets, and boiler plates, 116,161 tons; and wrought, all sorts, 127,556 tons.

For fuller details, consult Fairbairn, article Iron, *Encyclopædia Britannica*, 9th edition; Manufacture

of Iron and Steel, *Cabinet Cyclopædia*; Dr. Ure, *Dictionary of Science*; Brande, *Dictionary of Art, Science, and Trade*; Dr. Muspratt, *Chemistry applied to the Arts and Manufactures*; Bigelow, *Technology*; *Official Returns*, &c., &c.

IRON, APPLICATIONS OF. The applications of iron to the useful arts, and its employment for various purposes by the ingenuity of man, is a theme on which our limited space forbids us to enlarge. But its recent adaptation as a means of offence and defence in warfare is of so much importance to the interests of nations, that we cannot omit all reference to it.

Iron armour for the protection of ships of war and fortifications was suggested in America in 1812, and in France in 1821. Even in England, generally behindhand in the adoption of novel appliances, an experiment on the value of wrought-iron bars as an external defence for masonry, took place at Woolwich as early as 1827. The result, however, was not such as to induce a repetition of the experiment, and for several years the project was wholly forgotten. It was revived again in 1850, and at the commencement of the Russian war first practically realized by the French emperor. The French iron floating battery, engaged in the bombardment of Kinburn in 1855, proved so much more effective than its wooden rivals that the British Admiralty were induced again to turn their attention to the practicability of iron defences. A committee was appointed to conduct a series of elaborate experiments, which were not finally concluded until 1860, and the following result was obtained: That a good wrought-iron plate, $4\frac{1}{2}$ inches thick, backed with 18 inches, of teak, was proof against the 68-pounder and 7-inch breech-loader Armstrong gun, at a range of 400 yards. Acting upon these data, the Government ordered the construction of three floating batteries of iron, each carrying 1954 tons, with a mean draught of water of 8 feet 9 inches. They were formed of ribs of iron 6 inches deep, on which the armour and timber backing were placed.

But though these vessels were useful as coast defences for the protection of exposed towns and the mouths of rivers, their unwieldiness and want of sea-going qualities would prevent their general employment in naval warfare. The problem to be solved was the construction of iron-clad ships that should be as efficient men-of-war as the old 'wooden walls' of England, while invulnerable against the terrible discharges of modern artillery. For this purpose the *Warrior*, *Black Prince*, *Defence*, and *Resistance* were built. These ships were only partially cased in armour, their bows and stems being covered with nothing more substantial than $\frac{3}{4}$ -inch boiler plate, from a belief that if wholly iron-clad they would prove unmanageable in heavy seas. Their central battery was thus protected— $4\frac{1}{2}$ -inch wrought-iron plates, each 15 feet by 3 feet 2 inches, fastened by $1\frac{1}{4}$ -inch bolts, riveted on the inside; then a backing of 18 inches of sound hard teak, and a $\frac{3}{4}$ -inch wrought-iron skin on iron ribs, 18 inches apart. Each plate was about 15 feet long and 3 feet wide, and weighed four tons.

But the art of attack rapidly outstripped the art of defence, and such rapid advances were made in the improvement of artillery that the Admiralty

thought it advisable in 1861 to appoint a new committee, whose labours were continued until 1864. Numerous targets of iron, and iron and wood, were proposed by various inventors as models for the armour-plating of vessels of war, and at Shoebury-mess these targets were submitted to the severest proofs by exposure to the fire of the heaviest guns that Armstrong, Whitworth, and others could invent. Mr. Brande thus tabulates the general results of these experiments:—

1. Wrought iron of the softest quality is best adapted for armour plate, and the least approach to a steely quality should be avoided.
2. Very powerful machinery is absolutely necessary, and rolled plates are better than hammered.
3. Large and wide plates are better than small and narrow, all plates being weakest near the edges.
4. Tonguing and grooving weakens the plate, and tends to destroy the plate adjacent to that which is struck.
5. A combination of bars is inferior to a solid plate of the same weight or thickness.
6. A series of thin plates is similarly inferior.
7. Generally, no combination is so good as a solid plate, the resistance of which up to a certain point may be assumed to be nearly as the square of the thickness.
8. No advantage is gained by placing plates at an angle if the iron must be made thinner in consequence; or, in other words, iron of a given weight is most usefully employed in thick vertical plates.
9. Rigid backing is best for fortifications, but a soft backing yields to any distortion of the plate, distributes the effect over a larger area, and diminishes the damage to the general structure.
10. Wooden backing answers these conditions as well as, or better than, any other.
11. Increase of thickness of plate does not compensate for considerable diminution of backing.
12. All irregularities of surface, such as bosses, &c., tend to weaken the plate.
13. A facing of wood or other material saves the plate to some extent, but is easily destroyed by shell.
14. The bolts which fasten the plates should be of large diameter, at least two inches; countersunk bolts, with conical heads and double nuts, have been found to answer best.
15. Soft washers should be used to protect the fastenings.

The *Warrior* target, that is, the mode of armour-plating adopted for the protection of the *Warrior* ship-of-war, was for some time considered the most effective, but it was soon found that steel projectiles, both shot and shell, could penetrate it. A shell of 585 lbs. weight, containing 24 lbs. of powder, fired from the 13-inch Armstrong gun, went right through it, though the charge had been diminished so as to give the shell a velocity on striking equal to what it would have possessed at 2000 yards with the ordinary service charge. And though the thickness of the armour-plating has been increased and various expedients adopted to secure increased protection, it seems generally admitted that after we have arrived at the maximum thickness of iron which a ship will carry, our artillerymen will succeed in devising a projectile to penetrate it. Still, vessels of the class of the *Minotaur*, *Agincourt*, and *Northumberland*, will be very powerful assailants. They are 20 feet longer than the *Warrior*, 18 inches broader, and have two hundred tons (6021 tons) more burthen. They are completely armed from bow to stern. (See

Plate 'Iron-clads.') Similar protection is supplied to the cupola or shield ships designed by Captain Cowper Coles, and so called because they carry on their upper deck a revolving tower or cupola of iron, which affords complete shelter to the gunners, and enables heavy guns to be worked with facility, and trained in any direction. (See Plate 'Midship Section of Iron Cased Ship.')

While Great Britain has been steadily increasing and improving her iron-clad navy, other nations have not been idle. Turkey, Spain, Italy, and Denmark, have ordered plated vessels of our most eminent ship-builders, and France especially has run us very closely in the race. The latest addition to the imperial fleet is a formidable one, the ram *Taureau*, which will carry a rifled and hooped gun, weighing twenty-two tons, in her iron tower. The following particulars respecting this vessel is from the French papers:—It presents a very formidable, though by no means graceful aspect. Being intended for the defence of ports and roadsteads, it has a very small draught of water, and can therefore run into shallows where large vessels cannot approach it. Its prow is armed with a massive bronze cone, which, when driven at the rate of twelve knots an hour by an engine of 500 horsepower, will suffice to destroy the stoutest ship. The *Taureau* has two screws, which enable it to turn in a very short radius even when going at the rate of twelve knots an hour, whereas a frigate going at that speed could not turn in a circle of less than 700 yards in diameter. It is iron-clad from end to end to the depth of three feet below the water line.

Iron armour has also been suggested for forts, and it is evident that plates of any thickness might be employed for such a purpose—plates of a thickness which would defy the most powerful gun ever invented. The embrasures might be protected by shields, of which several kinds having been suggested, that which was introduced by Captain Inglis, R.E., appears to have found most favour in this country. It consists of slabs of wrought-iron crossing each other at right angles, the front layer being 6 inches, 7 inches, and 8 inches thick, and the rear layer 5 inches thick, secured through the centres by screw bolts with elastic washers under the nuts. This shield, when fired at with a 300-pounder Armstrong gun, was shaken, but not penetrated.

The iron-plated ships now laid down for the British navy (1866) are protected by a combination of armour and timber backing, adapted from an invention of Mr. Chalmers, but modified under the direction of the chief constructor of the navy. On the whole, our iron-clad fleet, in the opinion of competent judges, is the most powerful in existence, and presents the most perfect models.

IRON, MEDICINAL PROPERTIES OF. [CHALYBEATE SPRINGS.]

IRON PYRITES. Yellow sulphide of iron. A bisulphide composed of 20 parts of iron and 32 of sulphur. It is a very common and abundant ore of the metal, and has hitherto been principally employed for the production of the sulphate of iron, or *green vitriol*. Since the attempt to create a monopoly in the sulphur trade, it has been largely employed in the preparation of sulphuric acid.

IRONY (*σιγανία*), a refined species of ridicule,

which, under the guise of earnestness and simplicity, exposes all undue pretensions, even while it professes to honour and admit them. Of English writers Swift contains the strongest and the most numerous examples of irony.

IROQUOIS. [NORTH AMERICAN INDIANS.]

IRRADIATION denotes, properly, the emission of rays from a luminous object, but the word is generally used to signify an apparent enlargement of the disc of a celestial body, this enlargement being caused either by a deviation of the rays of light from a rectilinear direction, or by some illusion arising from the action of light on the eye.

It is a consequence of irradiation that objects which are in reality of equal magnitudes appear frequently to differ in size according to their colour or to the quantity of light which falls upon them. Sir William Herschel remarked ('Phil. Trans.,' 1783) that, when a bright circle was viewed together with a dark one on a bright ground, the latter always appeared smaller than the other.

IRRATIONAL QUANTITY. There are such things as magnitudes which are not in the proportion of any one number to any other; though if we may use numbers as great as we please, we can find a pair which shall be as nearly as we please in the ratio of any two such quantities.

According to the modern use of the term irrational, it simply means not expressible by a finite fraction. The word *ratio*, or its equivalent λόγος, does not here mean reason, in the common sense of the word, but mathematical proportion. A quantity whose proportion to the unit of quantity cannot be expressed arithmetically, that is, by a whole number or a fraction, is 'inexpressible by an arithmetical ratio,' or 'arithmetically irrational,' abbreviated into 'irrational.' This explanation is very important, since the student might otherwise be led to suppose that irrational meant unreasonable or absurd. Suppose, for example, that we have a geometrical problem which we solve by the application of arithmetic, taking a certain line to be unity. Suppose the problem thus reducible to the solution of $x^2 = 2$, or the quantity sought is such a fraction as multiplied by itself will give 2. The arithmetical answer is very simple; there is no such fraction. But is the problem therefore impossible? By no means; for the line required must be the diagonal of a square whose side is the linear unit. What, then, is the reason for our not being able to produce an arithmetical solution? Because the ratio of the line sought to the linear unit given is not to be expressed arithmetically, or is in the preceding sense irrational. The student has now arrived at the point where he must be taught (if he has not learnt it before) that arithmetic is not the science of all ratios or relative magnitudes, but only of the ratios or relative magnitudes of those quantities which are made by putting together quantities which are all equal to one another. The senses alone would never make this distinction, and those who desire nothing more than sensible evidence in their mathematical studies need not attend to it: unfortunately the present bent of such pursuits tends to inexactness, not explicitly avowed, but wearing the appearance of absolute rigour.

The student who begins to extract the square root of numbers is allowed to place the symbol of that

process over numbers which do not admit of its performance, as $\sqrt{2}$, $\sqrt{3}$, &c. Upon these symbols he reasons as if they represented fractions, and arithmetical deductions are drawn from thence; but when it is required to reduce them to practice, then the possibility of determining their arithmetical values is denied, and it is implied that they have an existence which can only be approximately represented. Thus, since 1.4142 multiplied by itself gives 2 very nearly, it is said that 1.4142 is very nearly the square root of 2. This method, which is indispensably necessary in practice, should not be allowed in perfectly strict reasoning. It cannot be just to say that 2 has no square root, but that since fractions very near to 2 have square roots, therefore these square roots are very near to the non-existent square root of 2. It is only in a properly extended arithmetic, which by express agreement admits of extended symbols of ratio, that it can be lawful to speak of the square root of 2.

IRRIGATION. Of all the substances which concur in the vegetation and growth of plants, water is the most essential. The warmer the climate, and the more rapid the evaporation, the more luxuriant is the vegetation, provided there be an abundant supply of water. This circumstance has suggested the plan of diverting streams from their original courses, and conducting them in channels to fertilize as great an extent of land as possible.

In China and in India, as well as in Egypt, ingenious methods of watering lands have been adopted from the most remote ages. No expense has been thought too great to secure a supply of water, and to distribute it in the most advantageous manner.

The whole art of irrigation may be deduced from two simple rules: first, to give a sufficient supply of water during all the time the plants are growing; and secondly, never to allow it to accumulate so long as to stagnate.

The supply of water must come from natural lakes and rivers, or from artificial wells and ponds, in which it is collected in sufficient quantity to disperse it over a certain surface. As the water must flow over the land, or in channels through it, the supply must be above the level of the land to be irrigated. But there must also be a ready exit for the water, and therefore the land must not be so low as the natural level of the common receptacle of the waters, whether it be a lake or the sea to which they run.

Along the banks of running streams nature points out the declivity. A channel which receives the water at a point higher than that to which the river flows, may be dug with a much smaller declivity than that of the bed of the river, and made to carry the water much higher than the natural banks. It may thence be distributed so as to descend slowly, and water a considerable extent of ground in its way to rejoin the stream. This is by far the most common mode of irrigation, and the shape, size, and direction of the channels are regulated by the nature of the surface and other circumstances, which vary in almost every situation.

When there is a considerable fall and a sufficient supply of water, a series of channels may be made, so situated below each other, that the second collects

the water which the first has supplied, and in its turn becomes a feeder to irrigate the lower parts of the declivity: a third channel receives the water and distributes it lower down, until the last pours it into the river. This is called *catch-work*, because the water is caught from one channel to another. It is by far the cheapest plan of irrigation, and as it can be applied to a hillside as well as to a level field, its adoption is rapidly extending. A small rill, which is often quite dry in summer, may still by judicious management be made to improve a considerable portion of land: its waters may be collected and allowed to accumulate in a pond or reservoir, and let out occasionally, so that none be lost or run to waste. If there is but a small quantity, it must be husbanded and made to flow over as great a surface as possible. If there is not a want of water, there may be a want of declivity to enable it to flow off, which, it should always be remembered, is an essential part of irrigation. Art may in this case assist nature by forming a passage for the water, either in its course towards the land to be irrigated, or from it after it has effected its purpose.

When the surface to be irrigated is very flat and nearly level, it is necessary to form artificial slopes for the water to run over. The whole of the ground is laid in broad beds, undulating like the waves of the sea; and the water, carried along the ridge of each bed, is allowed to flow down the slopes.

Experience has shown that there are particular seasons when the water has the best effect. During frost the water-meadows, having a current of water continually flowing over them, are protected from the effect of frost, and the grass will continue to grow as long as the water flows over it. Too much moisture, however, would be injurious, and the meadows are therefore laid dry by shutting the flood-gates whenever the temperature of the air is above freezing. By this management the grass grows rapidly at the first sign of spring. Before the dry upland meadows have recovered the effects of frost and begun to vegetate, the herbage of the water-meadows is already luxuriant; and by judicious management three or four crops of grass are obtained in each season, or only one abundant crop is made into hay, and the sheep and cattle feed off the others.

In hot weather much mischief may be done by injudicious flooding. In winter, on the contrary, the land may be covered with water for weeks without injury; and if an earthy deposit takes place, the subsequent fertility is greatly increased. But this is not properly irrigation: it is inundation, and the effects depend on entirely different causes. On the other hand, water may be carried in small channels through meadows without being allowed to overflow: this is watering, but not properly irrigating. The great advantage of water-meadows in England is not so much the increased quantity of grass or hay which is obtained when they are mown, as the early feed in spring, when all kinds of nutritive fodder are scarce.

When it is intended to form a water-meadow on a surface which is nearly level, the whole of the land must be laid in beds about 20 or 30 feet wide; the middle or crown of these beds being on a level with the main feeders, and the bottoms or drains on

a level with the lower exit of the water, or a little above it. Grass-seed being sown over these beds, the water may be let on for a very short time, to make them spring. As soon as the grass is two or three inches above ground, a regular flooding may be given, and in a very short time the sward will be complete. Instead of sowing seed, tufts of grass cut from old sward may be spread over the newly formed beds, and they will soon cover the ground.

It seems essential to the formation of a good water-meadow that the bottom be porous and free from stagnant water; hence under-draining is often indispensable before a water-meadow can be established; and a peat bog, if drained and consolidated, may have water carried over its surface, and produce very good herbage. If the soil is a very stiff clay, draining is almost indispensable where a water-meadow is to be made.

The usual time of letting on the water on water-meadows is just before Christmas, and it may continue to flow over the land as long as the frost lasts: in mild weather it may be turned off during the day and put on again at night until the frost is gone. The grass will soon begin to grow, and be ready to be fed off. When this is done, the water is immediately let on for a short time, and turned off again to allow the ground to dry after a few days' flooding, and the water is let on again at short intervals. The warmer the air is, the shorter time must the water be allowed to cover the meadows. By means of judicious irrigation good grass crops may be obtained, year after year, without any manure being put on the land.

Irrigation is not practised to such an extent in Great Britain as seems desirable. The whole of the water-meadows do not probably exceed 100,000 acres, and are chiefly confined to the south and west of England. On the Continent the great plains and valleys of the Po, Adige, Tagus, Douro, and other rivers, are systematically irrigated, and their fertility wonderfully increased in consequence. The system is also very extensively pursued in India, and is being extended in every direction in that country.

The distribution of liquid manure over the land answers the same purpose as irrigation; and from the satisfactory results which have attended this plan of increasing the fertility of the soil, there can be no doubt that it will be more and more resorted to. An extensive tract of land lying between Portobello and Leith has for some time been covered with the sewage of Edinburgh, and now yields a rent of from 20*l.* to 40*l.* an acre. Grass is cut on it from three to five times a year, and as much as ten tons an acre have been obtained at a cutting. The advantages of this application of liquid manure have long been shown on a small scale by Mr. Meehi, at Tiptree Farm, near Kelvedon.

Great improvements have recently (1866) been made in mechanical appliances for carrying on this work. Among these we may notice Messrs. J. Warner and Sons' new chain pump. This machine was made expressly for India. It requires little fixing. It throws a large quantity of water into the irrigating canals, and is so simple that any native may work or repair it. See Plate 2, 'Irrigation,' figs. 1 and 2; fig. 3 represents the horse gear

used to work the chain pump. Plate 1 represents the force pump for irrigation by the same makers.

IRTISCH. [SIBERIA.]

IRUN. [BASQUE PROVINCES.]

IRVINE. [AYRSHIRE.]

IRVING, EDWARD, A.M., a famous pulpit orator, and founder of a religious sect, was born at Annan in Dumfriesshire in the year 1792. He studied at the University of Edinburgh, and there he acquired such marked distinction in the exact sciences, that before reaching his seventeenth year he was recommended by Professor Leslie to the situation of teacher of mathematics in the burgh school of Haddington. In the following year he was appointed to a similar office in Kirkcaldy, where he remained nearly seven years, at the same time laboriously studying theology and attending at intervals the divinity hall at Edinburgh, with the view of entering the church. In 1819 he was licensed as a preacher in connection with the Established Church of Scotland by the presbytery of Annan; and happening to preach in St. George's church, Edinburgh, Dr. Chalmers, who was one of his hearers, was so favourably impressed with his discourse that he appointed him his assistant in the parish of St. John's, Glasgow. After spending three years in Glasgow, perhaps the happiest and most useful period of his life, he was invited to become the pastor of a Presbyterian chapel in Cross Street, Hatton Garden, London, attached to the Caledonian Asylum. He accordingly settled in London in August, 1822. The chapel was at that time nearly empty, and was besides situated in an obscure and unfavourable locality; but in the course of a few weeks Irving's remarkable style of oratory caused an extraordinary sensation in the metropolis, and the mean-looking, dingy sanctuary in Hatton Garden was thronged, Sabbath after Sabbath, with statesmen, philosophers, poets, painters, literary men, merchants, peers, fashionable ladies, mingled with shopkeepers and mechanics, while many hundreds were unable to obtain admission. About a year after his settlement in London he published a volume of discourses, under the title of—'For the Oracles of God, Four Orations: For Judgments to come, an argument, in nine parts,' three editions of which were called for in little more than six months. Irving's popularity continued with no abatement for about two years, and a new and stately church was erected for him in Regent Square, capable of accommodating at least two thousand persons. But, unfortunately, his thirst for applause had grown to a disease, and strong excitement had become a necessity of his nature, to be maintained at any cost. He now devoted himself with characteristic ardour to the exposition of unfulfilled prophecy, and in a bulky volume, entitled 'Babylon and Infidelity foredoomed by God,' 1826, he ventured to predict the exact date of the final overthrow of popery and infidelity, and confidently fixed upon 1868 as the period when the millennial reign of Christ was to commence on earth. He next adopted the opinion that it was want of faith alone which prevented the miraculous gifts conferred upon the primitive church from being enjoyed by the church in modern times; and having for some time earnestly prayed for, and eagerly expected the return of these gifts, he soon became infected with the religious frenzy which at this period broke out at Row,

on the Frith of Clyde, and declared his firm belief in the truth of the claims which some of his fanatical followers made to the power of working miracles and speaking in unknown tongues. And proceeding rapidly in the downward path of error, he began to disseminate, both from the pulpit and the press, heretical notions respecting the alleged peccability of our Lord's human nature. His erratic behaviour at length attracted the attention of the ecclesiastical courts, and after a formal trial for heresy he was deposed from the office of the ministry in the Church of Scotland. He continued, however, to preach to a numerous body of devoted adherents, who built a new chapel for Irving in Newman Street, where he continued to preach to the close of his life, and about fifty thousand persons throughout England adopted his views. His iron constitution, however, now began to give way under his incessant labour and excitement; he repaired to Scotland for change and repose, but died in Glasgow, December 8, 1834, in the forty-third year of his age. In addition to the works already mentioned, he published a missionary 'Oration' in 1824; an Introductory Essay to Bishop Horne's Commentary on the Psalms in 1826; 'The Coming of the Messiah in Glory and Majesty, by Juan Josafah Ben Ezra, a converted Jew, translated from the Spanish,' 1827; and 'Sermons, Lectures, and Occasional Discourses,' in 3 vols., in 1828. An admirable 'Life' of this extraordinary man has recently been published by Mrs. Oliphant, the well-known novelist.

IRVING, WASHINGTON, one of the most pleasing and popular of American writers, was born at New York, on the 3rd of April, 1783. He was of Scottish origin, his father belonging to a family of Irvings long settled in the Orkney Islands. The earliest contributions Washington made to literature were light sketches of men and manners, published in 1802 in the *New York Morning Chronicle*. In 1803 he travelled extensively in Southern Europe, paid a visit to England, returning home in 1806, and contributed a series of humorous essays to a periodical called *Salmagundi*. In 1809 Irving published his first book, the 'History of New York, by Diedrich Knickerbocker,' a burlesque chronicle written in a vein of such quiet humour that it has sometimes been taken for a veritable history. About this time Irving was admitted a partner in the thriving commercial house which his brothers had inherited from their father. He also edited the *Analectic Magazine*. In 1816 he visited England, and was introduced to Sir Walter Scott. In the same year disaster overtook the firm to which he belonged, and he turned to literature, not as a pastime, but a resource. Two eminent publishers refused the 'Sketch Book,' part of which had appeared in New York; but Scott came to the rescue, and advised Murray to publish it. Its success was immediate and immense. For his next work, 'Bracebridge Hall,' the publisher offered a thousand guineas without seeing the MS. 'Tales of a Traveller' followed in 1824. During a residence in Madrid, Irving wrote the 'Life and Voyages of Columbus' (which was published in 1828, and remains the standard work on the subject), 'The Voyages of the Companions of Columbus,' 'The Conquest of Granada,' 'The Alhambra,' 'Legends of the Conquest of Spain,' and 'Mahomet and his Suc-

VOL. VII.

cessors,' which were published at intervals up to the year 1849. In 1829 he was appointed secretary to the American Legation in London. In 1831, the University of Oxford conferred on him the degree of LL.D.; and of the two gold medals placed by George IV. at the disposal of the Royal Society of Literature, Irving received one, and Mr. Hallam the other. Resigning his diplomatic functions in 1831, he returned to America a distinguished and respected man. A visit to the Rocky Mountains produced his 'Tour on the Prairies,' afterwards republished, with his 'Recollections of Abbotsford and Newstead, in the *Crayon Miscellany* of 1835. In 'Astoria,' 1836, he sketched the history of the remarkable enterprise which his friend John Jacob Astor had set on foot many years before, to carry the fur trade across the Rocky Mountains. The 'Adventures of Captain Bonneval' came from his pen in 1837, and numerous stories and essays in the *Knickerbocker Magazine*, afterwards collected under the title of 'Wolfert's Roost.' To 1841 belongs his 'Life and Poetical Remains of Margaret Davidson.' In 1842 he was appointed minister to Spain. Returning to America in 1845, he lived on his estate called Sunnyside, on the banks of the Hudson, twenty-five miles from New York, where he dispensed a liberal hospitality. In 1849 he published his 'Life of Goldsmith,' and in 1859 completed his last and best work, 'The Life of Washington.' He died at Sunnyside, in his seventy-eighth year, on the 28th November, 1859, having enriched the literature of his country with many excellent works, some of them among the most graceful in the English language, and bequeathing to the biography of authorship a life singularly pure, honourable, and happy. His life has been recently published by his nephew, Pierce Irving.

IRVINGITES, a name erroneously given to the supposed followers of Edward Irving. Irving, in common with many others, believed that God in these last days had restored apostles and prophets, together with other gifts of the Spirit, peculiar to this dispensation, for the blessing of the whole Church of Christ. In public estimation he was the most prominent person in this movement, though himself neither claiming nor possessing any special gift. Believing it to be a work of God, he to the very last abhorred the idea of his name being associated with it. His supposed followers, while honouring him very highly for his works' sake, and for his many noble qualities, consistently repudiate the idea of being called by his name, and refuse to take any other name than what belongs to the whole Church of Christ—the 'One Catholic and Apostolic Church.'

ISABELLA OF CASTILE. [FERDINAND V., of Castile.]

ISABELLA THE CATHOLIC, ORDER OF, a Spanish order of knighthood, founded by Ferdinand VII., in 1815, as a reward for the defence of the possessions of Spanish America. The sovereign is the head of the order, and it has the three classes of grand-crosses, commoners, and knights. It is now conferred for all kinds of services.

ISÆUS, one of the ten Athenian orators, was a native of Chalcis, or, according to other accounts, of Athens. The vigour of his talent belonged to the period after the Peloponnesian War, which ended B.C. 404, and he lived to the time of King Philip.

F F

He was a pupil of Isocrates, instructed Demosthenes, and enjoyed the society of the chief philosophers of his time.

Eleven of the orations of Isæus are extant, all treating of matters relating to wills and the succession to the property of testators, or persons intestate, or to disputes originating in such matters. From these orations we derive much information about the law of Athens on the disposition of property by will and in cases of intestacy, and also respecting many of the forms of procedure.

Dionysius says, that with Isæus originated that vigour and energy of style which his pupil Demosthenes carried to perfection.

The best edition of the text of Isæus is by Bekker. The translation of Isæus by Sir William Jones (1779, quarto) is somewhat deficient in critical accuracy, as well as wanting in force.

ISAIAH, one of the most celebrated of the Hebrew prophets, but of the time in which he lived little more is known than he has himself told us in the superscription of his book. It appears that he was the son of Amoz or Amotz, who, however, was not the prophet Amos, who prophesied in Israel in the reign of the second Jeroboam. It seems tolerably clear that he was a native of the kingdom of Judah; and that he resided at Jerusalem is evident from several passages of his prophecies; that he was married; and that he had two sons in the reign of Ahaz, to whom he gave names symbolical of important events in the future history of the Jews (vii. 3; viii. 1, 2). The Scripture says nothing further of him; but the uniform tradition of the Jews is that he was put to death in the time of Manasseh, by being sawn asunder.

The prophetic ministry of Isaiah was of long duration. The superscription acquaints us that he prophesied in the reigns of Uzziah, Jotham, Ahaz, and Hezekiah. The vision in chap. vi., which has every appearance of expressing an introduction to the prophetic office, is dated 'in the year that King Uzziah died.' Uzziah died in 759 B.C.; and as we have an explicit statement that Isaiah was engaged in his prophetic work till the fifteenth year of Hezekiah, in 712 B.C., we have an interval of forty-seven years, during which, at the lowest computation, Isaiah exercised his prophetic office. But it is probable that he lived much longer. Hezekiah himself lived fourteen or fifteen years after that date; and the statement in 2 Chron. xxxii. 32, that 'the rest of the acts of Hezekiah' were written 'in the vision of Isaiah,' seems to imply that he survived him, and wrote the history of his reign down to the time of his death. If he survived Hezekiah, he probably, as the tradition already alleged intimates, lived some time into the reign of Manasseh; but if we reckon only to the first year of that reign, the interval from the last year of Uzziah is sixty-two years, and supposing that Isaiah was not more than twenty at the commencement of that period, he must have been above eighty at the time of his death.

Regarded in the order of time, the writings of Isaiah would form the fifth of the prophetic books; for Joel, Jonah, Hosea, and Amos were his predecessors. Yet is this book most properly placed first in the collection, as well on account of the transcendent importance and the sublimity of the predic-

tions which it contains, as on account of its extent—the book of Isaiah being larger than any other prophetic book, and indeed exceeding in bulk the writings of all the twelve minor prophets taken together.

The peculiar sublimity of Isaiah's prophecies, both in their style and objects, has directed the attention both of Jews and Christians more strongly to this book than to any other in the prophetic canon of the Old Testament. It has the very important distinction of being more frequently quoted in the New Testament than any other of the sacred books, the Psalms excepted: and the distinct manner in which the divinely inspired writer speaks of the birth and sufferings of Christ, and the glories of his kingdom, has ever rendered it eminently instrumental in the conviction of the unbelieving, in confirming the doubtful, and in strengthening the faint-hearted. It should be added that eminent modern critics are of opinion that some portions of the book (especially chapters xii. and xiii.) are by a different writer, of the time of Jeremiah or even the later prophets.

Bishop Lowth's English translation of the Prophecies of Isaiah, first published in 1778, contains a large body of useful notes, and has been frequently reprinted.

ISATINE, a chemical compound, which forms orange-red or hyacinth crystals of a brilliant lustre, and is obtained by means of sulphuric acid and bichromate of potash, from oxidized indigo. This compound dissolves in caustic potash, and the liquid yields, on evaporation, isatite of potash as a crystalline salt. 'This salt gives with acetate of lead a white precipitate, isatate of lead, which, when decomposed by sulphuretted hydrogen, yields a solution of the acid. Isatic acid is decomposed from this solution by spontaneous evaporation, as a white powder.' (Turner.)

ISATIS. [WOAD.]

IS'CHIA, the ancient *Enaria*, an island situated at the northern entrance of the Bay of Naples, the smaller island of Procida lying between it and the promontory of Misenum on the mainland. It is mountainous, and abounds in most enchanting scenery. The highest summit, called Epomeo, which is an extinct volcano, rises about 2500 feet above the sea. Strabo calls this island *Pitheciusæ*, from *pithecus*, an earthen vessel, the clay of the island being used for earthenware from the remotest time. The soil is very fertile, and produces corn, abundance of superior wine, and all sorts of fruit. The hills are covered with chestnut trees. Sulphur is abundant, and the mineral springs at Casamicciola are annually resorted to by summer visitors. The island is about 20 miles in circuit, and contains 25,000 inhabitants, who are partly employed as fishermen, and in manufactures of alum, straw hats, baskets, and earthenwares. Ischia is divided into two cantons, and contains the small towns of *Ischia*, which is a bishop's see, and has a castle (population, 6545); *Foria*, which is the most commercial place on the island (population, 5791); and *Casamicciola*, near which there is excellent clay, of which a great quantity of pottery is made and sent to Naples. The latter place has thermal springs and baths, and the inhabitants number 3690.

ISEGHEM. [FLANDERS, WEST.]

ISER. [BAYARIA.]

ISÈRE, a department in France, formed out of a portion of Dauphiné, is bounded E. and N. by Savoy and the department of Ain, S.E. and S. by the department of Hautes-Alpes, S.W. and W. by those of Drôme and Rhône. It lies between $44^{\circ} 42'$ and $45^{\circ} 52'$ N. lat., $4^{\circ} 42'$ and $6^{\circ} 20'$ E. long.; its length from N.W. to S.E. is 94 miles; the average width is 41 miles. The area is 3200 square miles, and the population at the last census was 577,748.

General Aspect.—The department presents lofty Alpine mountains, peaks covered with snow that never melts, glaciers, dark pine forests, numberless steep, narrow, and abrupt gorges, torrents, waterfalls, and extensive plains towards the north and in the centre, the whole forming perhaps the most varied and picturesque scenery in France, ranging between the extremes of the bleakest barrenness and the most smiling and luxuriant fertility. The cols of Saix and Sept-Laux, and the peaks of Granier and Belledonne, rise respectively to the height of 10,968, 9742, 9840, and 9781 feet above the level of the sea. The mountains abound in grottoes of great extent, and are rich in stalactitic concretions. The lakes are numerous, but small. There are no navigable canals; but canals and rills of irrigation are employed very extensively in most of the valleys and plains. Every spot capable of cultivation is carefully tilled; the mountain sides are shaped into terraces, which are formed with carried earth, supported by walls of dry stones; and crops are grown at the height of 2700 feet above the level of the valleys.

The arrondissement of Grenoble contains no plains; the tillage is confined to the valleys and mountain slopes. The valley of Grésivaudun, remarkable for its extraordinary fertility and high cultivation, is watered in its whole length by the Isère, and extends from the point where that river enters France to its junction with the Drac in the neighbourhood of Grenoble, a length of 29 miles, with an average breadth of 3 miles. It is inclosed in its whole extent by two chains of mountains of great and varied beauty, the lower slopes of which are converted into corn fields, meadows, orchards, and plantations; the central parts are covered with forests of oak, chestnut, and pine, or clothed with pasture; while the summits and crests are covered with snow or with naked rocks. In this valley the walnut, mulberry, and vine flourish. Wheat, barley, maize, hemp, clover, &c., are produced in great abundance. Rye and oats are the chief crops in the mountain districts. Oxen are employed in farm-work. Numerous flocks from this and the neighbouring departments graze upon the mountain pastures during the summer. The arrondissement of St.-Marcellin presents towards the north a vast plain, known under the names of Bièvre and Côte-St.-André, consisting of a dry gravelly soil, which is tolerably fertile and well cultivated. The centre of this arrondissement is hilly, and contains some good wheat land. Another part of the arrondissement is the valley of Tullins, a prolongation of that of Grésivaudun, to which it yields neither in beauty nor fertility. The southern part of the arrondissement of La-Tour-du-Pin, known as the Terres Froides (cold lands), consists of high ridges divided by narrow vales, while the northern part consists of hills of moderate height, intersected by moist and marshy plains. In this part are the lakes of Paladru

and Lempis, and the extensive morasses of Bourgoin. The arrondissement of Vienne presents in its northern part a vast dry sandy plain, on which rye is the chief crop; in the central parts it is covered with hills, the lower slopes of which are well cultivated and very productive, while their summits are covered with wood; to the south this arrondissement comprises the extremely fertile plain of Valoir, which yields corn, wine, oil, and silk.

Rivers.—The department takes its name from its principal river, the *Isère*, which, rising on the western slopes of the Graian Alps in Savoy, flows in a general westerly direction to Montiers, whence its course is N.W. for a few miles, then S.W. to its junction with the Arc and as far as Montmeillan, where it becomes navigable. Here its course is nearly S. to Grenoble, where it is joined by the Drac from the left bank: below this point it makes another bend first to N.W., then to S.W., passing St.-Marcellin, below which town it enters the department of Drôme, and falls into the Rhône a few miles above Valence after a course of 150 miles, 90 of which are navigable. This river, though subject to disastrous floods, is of moderate width, but very deep; its waters are always of a blackish tint, owing to the débris which it receives from the slate quarries of the Tarentaise. Of the other streams, the most important are the *Drac* [*ALPES, HAUTES*]: the *Romanche*, which drains the south-east of the department and joins the Drac on the right bank, a few miles S. of Grenoble: the *Bourbre*, which rises S. of Virieu, and flowing past La-Tour-du-Pin and Bourgoin enters the Rhône on the northern boundary of the department; the *Guiers*, which is formed by the union of the *Guiers-Vif* and the *Guiers-Mort* (two streams that run down from the mountains of the Grande-Chartreuse), and flows along the frontier of Savoy from Les-Echelles to its junction with the Rhône, a few miles S. of Belley. The *Rhône* forms the northern and western boundaries of the department, and is navigable. Salt and other articles are conveyed in barges from the Rhône up the Isère; the transports down the latter are iron, hemp, linen, woollen cloth, &c.

Natural Products.—The department contains 2,078,799 acres, of which 38,276 are covered with rivers, lakes, canals, &c. The productions are of the most varied description, including wheat, rye, barley, maize, buckwheat, peas and beans, potatoes, fruits of all kind, almonds, medicinal plants, hemp, &c. Vines are mostly grown in the fertile valleys, trained either to greenwood supports of maples or cherry-tree, or to dry tall poles of chestnut wood; vines thus grown are called high vines (*hautains*). But on the hill slopes, in favourable situations and in the Rhône district, the low vines, as they are called when unsupported, produce a stronger better-keeping wine, and more fitted for transport. The produce of wine in ordinary years is about 5,500,000 gallons, the best of which is produced in the neighbourhood of the Rhône. Horses, asses, and cows are numerous, but small, the former being celebrated for their activity; mules of large size are reared in the mountains; sheep are bred in great numbers, and yield a fine silky wool; pigs, goats, and poultry are plentiful. The rivers and lakes abound in fish. Game is abundant; among the wild animals are the bear, boar, wolf, chamois, ibex, porcupine, weasel, red

and gray partridge, &c. The mulberry grounds are extensive.

The climate is healthy: cold in winter, very hot in the valleys and plains in summer. The prevailing winds are from the north and north-west; about eighty-five days in the year are rainy; hail-storms are sometimes very destructive.

In mineral wealth the department is very rich. Iron, lead, copper, and coal mines are worked; gold and silver mines have been worked, but are now abandoned. In the year 1837 a vein of platina was discovered in the valley of the Drac. White marble, granite, porphyry, gypsum, and slate are quarried; antimony, zinc, cobalt, rock-crystal, lithographic stones, lignite, vitriol, and sulphur are found.

Manufactures.—The industrial products consist of sailcloth, table and household linen, gloves, soldiers' uniforms, cannons, calicoes, printed cottons, oil, turpentine, liqueurs, and mineral acids. The gloves called Grenoble, from the place where they are made, bear a high reputation. There are iron, copper, and lead foundries, steel works, zinc and copper rolling factories, marble sawing mills, paper and vellum works, naileries, dyehouses, glass works, cotton yarn manufactories, and silk-throwing establishments.

Divisions, Chief Towns, &c.—The department is divided into four arrondissements, as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1863.
Grenoble, . .	20	212	216,462
La-Tour-du-Pin, . .	8	123	131,547
St.-Marcellin, . .	7	84	82,329
Vienne, . .	10	131	147,410
Total, .	45	550	577,748

Of the arrondissement of Grenoble and of the whole department the capital is GRENOBLE. *Allevard* stands in a high valley N.E. of Grenoble, watered by the Breda, a feeder of the Isère, and has 3180 inhabitants, who are chiefly employed in the neighbouring iron mines, forges, smelting furnaces, and foundries, the machinery of which is driven by the Breda. There are also some mineral springs, with a temperature of 96° Fahrenheit, but of small repute. *Bourg-d'Oysans*, S.S.E. of Grenoble, in the picturesque valley of the Romanche, which is hemmed in by high wooded mountains, echoing with numerous cascades, has an ecclesiastical college, and 2796 inhabitants, who manufacture cotton, and work in the lead and rock-crystal mines of the neighbourhood. *St.-Laurent-du-Pont*, 20 miles N. from Grenoble, is most picturesquely situated at the foot of very high and almost perpendicular mountains, on the road to the monastery of the Grande Chartreuse, which was founded by St. Bruno in 1084 in a wild and rocky defile; population, 1761. *Mens*, 25 miles S. from Grenoble, stands among the Trièves mountains, and has 1903 inhabitants, important linen manufactures, and glass factories. *La Mure*, S. of Grenoble on the road to Gap, situated at the extremity of the valley of the Matésine, which is inclosed by the Trièves mountains, has 3628 inhabitants, who manufacture coarse linen and leather, and work in the coal mines and marble quarries near the town. *Vif*, 10 miles

S. from Grenoble, has potteries, silk-throwing factories, and 2417 inhabitants. *Villard-de-Lans*, near the right bank of the Bourne, has a population of 2047. *Vizille*, in a fertile plain on the right bank of the Romanche, has an ancient castle now converted into a factory for printed cottons, and contains 3546 inhabitants. *Voiron*, N. of Grenoble, a well-built town of 9637 inhabitants, stands at the foot of a hill on the Morge, a small feeder of the Isère, which drives the machinery of several industrial establishments. The principal manufactures are cloth, chip hats, silk-stuffs, canvas, liqueurs, soap; there are also iron and steel works, paper and hemp mills, naileries, and tan-yards. *Voreppe*, S. of Voiron, has oil and corn mills, tan-yards, and 2887 inhabitants.

In the arrondissement of La-Tour-du-Pin the chief town, *La-Tour-du-Pin*, stands on the left bank of the Bourbre, on the road from Lyons to Chambéry, and has 2201 inhabitants, and some beet-root sugar factories. It was formerly important on account of its fortifications, of which some remains are extant. The tribunal of first instance is at *Bourgoin*, a town of 4851 inhabitants, situated among hills at the junction of three small rivers, and at the point where the Lyons road branches off southwards to Grenoble, and eastwards to Italy through Chambéry. Its situation is favourable for trade, but unhealthy on account of the marshes and bogs near it. Its manufactures are printed calicoes, canvas, cotton cloth and yarn, thrown silk, and beet-root sugar; there are also some paper mills. *Crémieux*, 6 miles N. from Bourgoin, has 2370 inhabitants, and is famous for its poultry. It stands at the foot of a chain of calcareous hills, in which is the famous grotto of *La Balme*, reckoned as one of the seven wonders of Dauphiné. The grotto consists of two long galleries, one facing the entrance, the other to the right, and both contain beautiful stalactites; in the former there is a lake of pellucid water, the transit of which to and fro occupies one hour, and is made by torch-light in a boat kept for the purpose. *Le-Pont-de-Beau-voisin* is on the Guiers, which divides the town into two portions, the largest of which is in Sardinia. The population on the French side is 1871; on the Sardinian, 1388—total, 3259. The river is crossed by a bridge of one arch.

In the arrondissement of St.-Marcellin, the chief town, *St.-Marcellin*, is situated 21 miles W. from Grenoble, in a pretty country at the foot of a vine-clad hill, at a short distance from the right bank of the Isère, and has a tribunal of first instance, a college, and 3295 inhabitants. The town is surrounded with walls pierced by four gates; it is well built, with straight streets, ornamented with fountains. *St.-Etienne-de-St.-Géoirs*, 10 miles N. from St.-Marcellin, on the Doleur, has a population of 1857. *Rives*, N.N.E. of St.-Marcellin, is situated in a smiling valley, watered by the Fure, and has 2506 inhabitants. This town is the centre of considerable manufactures of iron, steel, paper, crape, and silk handkerchiefs; the steel forges, of which there are a large number in the town and neighbourhood, are famous for the excellence of their products. *Roybon*, N.W. of St.-Marcellin, has manufactures of coarse woollens and 2128 inhabitants, partly engaged in steel-works. *Tullins*, formerly a well-fortified town, stands a few miles S. of Rives in a beautiful valley,

and has 4566 inhabitants. It is surrounded by iron forges, steel works, copper foundries, and hemp-dressing establishments. Arms and tools of various kinds are manufactured here. *Vinay*, 5 miles N.E. from St.-Marcellin, has iron works, silk-throwing establishments, and 3377 inhabitants.

In the arrondissement of Vienne the chief town is *Vienne*, the *Vienna* of the Allobroges, and the capital of the first and second kingdoms of Bourgogne. It stands in $45^{\circ} 31' 28''$ N. lat., $4^{\circ} 52' 11''$ E. long., at a distance of 45 miles N.W. from Grenoble, on the left bank of the Rhône, which is lined with quays and crossed by a suspension-bridge. The town has tribunals of first instance and of commerce, a consultative chamber of manufactures, a college, and, in 1861, 19,559 inhabitants. Hemmed in between steep hills and the river, Vienne has a much greater length than breadth; it is, like most ancient towns, ill-built, with narrow winding streets, with the exception of that traversed by the road from Lyons to Marseilles. It contains some Roman remains, among others a temple now converted into a museum, a triumphal arch, some vestiges of an amphitheatre on Mont-Pipet, and S. of the town, near the gate of Avignon, a pyramidal obelisk, called *Plan-de-l'Aiguille*, which is 46 feet high, and constructed with cut stone without cement. The modern structures of most note are the fine Gothic cathedral, the church and cloisters of the former abbey of St.-André-le-Bas, the cavalry barracks, the public library of 10,000 volumes, the college, which is one of the finest structures of the kind left by the Jesuits, the hospitals for the sick and poor, the corn market, and the abattoir. The Gère, which joins the Rhône at Vienne, drives the machinery of several factories. This town is one of the principal seats of the woollen manufactures in the south of France; common cloth, pasteboard, soap, leather, glass bottles, paper, chemical products, &c., are also made; and there are establishments for reeling and throwing silk, dye-houses, iron furnaces, steel works, sheet-copper and lead works, copper and brass foundries. The commerce of the town is composed of its industrial products, and of wine, zinc, &c. In its vicinity are lead and silver mines; and near it also, at Ampuis, the celebrated wine called *Côte-Rotie* is made. It has a station on the line of railway to Avignon. A council was held here in 1311, which abolished the order of the Templars. Vienne formerly had an archbishop of its own; but the archiepiscopal province is now united to that of Lyons. *Beaurepaire*, S.S.E. of Vienne, has cloth factories, corn and fulling mills, and 2661 inhabitants. *La-Côte-St.-André* stands at the foot of a hill, in a pretty situation on the Frette, 21 miles S.E. from Vienne, and has 4234 inhabitants, who manufacture the celebrated liqueur called *Eaux de la Côte*, pyroligneous acid, wax candles, and plate glass. *St.-Jean-de-Bournay*, 14 miles E. from Vienne, on the Veronne, a small stream that drives the machinery of several factories and then loses itself underground, has 3501 inhabitants, who manufacture sail-cloth, woollen plaids, beet-root sugar, and leather.

The department forms the see of the bishop of Grenoble; is included in the jurisdiction of the *Cour Imperiale* of Grenoble, and of the University Academy of Lyons; and belongs to the 22nd Military Division,

of which Grenoble is head-quarters. It returns four members to the Chamber of Deputies. (*Annuaire pour l'An 1866.*)

ISERNIA, a town in the province of Campobasso, South Italy, having 8584 inhabitants, some of whom are employed in manufactures of woollens, paper, and earthenware. It was nearly destroyed by an earthquake in 1805. It is the see of a bishop, and near it the first battle between the Sardinian and Neapolitan troops took place on the 17th October, 1860. The town is surrounded by scenery of most romantic beauty.

ISISIA, certain festivals held among the Romans in honour of Isis, the Egyptian goddess. They were originally brought from Egypt, but on account of their licentiousness were suppressed, u.c. 696; though they were restored by Commodus about 200 years afterwards. The priests were called *Isiaci*.

ISIDORE of Charax lived probably in the first century of our era. It appears from Athenæus ('Deip.' iii.) that he wrote an account of the Parthian empire, of which there is only a small part extant, entitled *Στασιαὶ Παρθίων*, or the 'Parthian Halting-places.'

ISIDORE, SAINT, of Pelusium in Egypt, lived in the beginning of the fifth century, and wrote, according to Suidas, '3000 epistles, explaining the divine Scriptures.' Upwards of 2000 are still extant. They have been published in Greek and Latin by Scholt, Paris, 1638. Dr. Heumann has published a 'Dissertation on Isidore' (Hanover, 1738, 4to.), in which he argues that most of the letters are fictitious, and not a real correspondence.

ISIDORE, SAINT, bishop of Seville, from 595 or 596 to 636, was born at Carthagena. He was considered by the Council of Toledo (650) as the most learned man of his age. The works of Isidore, which are numerous, have been published by Du Breul, Paris, 1601, and Cologne, 1617; at Madrid, 1778, and by Arevali, Rome, 1797, 1803.

ISINGLASS (German, *häusen-blase*, 'the air bladder of the sturgeon;') *colle de poisson*, is obtained from the air bag or 'sound,' as it is sometimes termed, of various fishes, many of which are still unknown. The finest kinds are produced by species of the *Acipenser* and some other genera, as the *Morrhua*, *Silurus*, and *Gadus*. The method of preparing the air bags for sale differs considerably, according to the country in which it is conducted. The commercial *pipe*, *purse*, and *lump* isinglass consist of the bag desiccated but unopened. The *leaf* and *honeycomb* kinds are examples of the bladder cut open and dried unfolded; in the staple and book varieties it is folded, while in the ribbon isinglass it is rolled out. It is picked or cut before importation into Great Britain.

The isinglass produced in the Russian empire is principally obtained from the sturgeon. These cartilaginous fishes constitute the genus *Acipenser*. But this is not the only genus from which isinglass is obtained in Russia, for it is also procured from the *Silurus glanis*, which Dr. Royle suggests may be the source of the Samovey isinglass of commerce. Brande thus describes the preparation of Russian isinglass:—The swimming bladder is cut open, washed, and then exposed to the air, with the inner silvery membrane turned upwards. The latter is then stripped off, and placed in damp cloths, or left in the outer covering and prepared or kneaded. It is then taken

out of the cloths, and either merely dried (*leaf isinglass*) and twisted in a serpentine manner between three pegs into the shape of a horseshoe, heart, or lyre (*long and short staple*), or folded in the manner bookbinders fold printed sheets of paper (*book isinglass*). Several kinds of leaf isinglass are imported from Russia. The finest kind is that from Astrakhan, one variety of which is said to be from the Beluga, *Acipenser nuso*. These are imported from St. Petersburg. The Samovey leaf is an inferior kind from Taganrog. Sisane leaf is the produce of a small fish, each piece measuring only about two and a half inches each way, and weighing about a drachm; it looks like pieces of dried bladder, marked by two fibrous or muscular bands. Other descriptions are imported from Brazil, New York, Hudson's Bay, and the East Indies.

The more common kinds of isinglass, especially the coarse Brazilian, are used by brewers for fining beer. They are also employed for the clarification of wines and various other liquors.

In 1864 the quantity of isinglass imported into the United Kingdom was 2748 cwts., value 96,007*l.*; of which 1045 cwts. were from Russia, 686 cwts. from Brazil, 393 cwts. from Bombay, and 354 cwts. from Singapore. The Russian isinglass is worth three times as much as any other, being 56*l.* per cwt. In same year 261 cwts., value 9118*l.*, were exported.

ISIS, one of the chief deities of the Egyptians, the wife of Osiris, was represented as the Goddess of Fecundity, and the cow was sacred to her. The annual festival of Isis in Egypt lasted seven days, during which a general purification took place. The priests of Isis observed perpetual chastity, their heads were shaved, and they went barefooted. The goddess was often represented as a woman with the horns of a cow. She also appears with the lotus on her head and the sistrum in her hand; and her head in some instances is seen covered with a hood. Heads of Isis are a frequent ornament of Egyptian capitals on the pillars of the temples. By the Greeks she was generally identified with Ceres; by the poets and philosophers she was regarded as the type of Pantheistic divinity.

ISIS HIPPU'RIS, a genus of corals inhabiting the Indian seas, the axis of which is formed of a

Isis hippuris.

series of calcareous joints, united together by horny rings. It belongs to the family *Gorgonidae*, which constitutes the third family of asteroid polypes.

Most of the species possessing a horny axis grow in a more or less arborescent form. But in some species the longitudinal branches are united at regular intervals by a number of transverse pieces, which are composed of a continuation of the horny axis, and bear polypes like the main stem and branches. *Isis nobilis* is the name now generally given to the red coral of commerce (*Corallum rubrum*) found in the Mediterranean.

ISLAM. [MOHAMMED.]

ISLANDS. The formation of islands, at different periods, is among the most remarkable phenomena in the great history of nature. Some have arisen from the coral beds in the bosom of the ocean, and others from volcanic action, or the operations of the central fires of the globe, by which the primary rocks of the earth's crust, with their superincumbent depositions, have been raised from their innermost depths to the surface of the ocean. Of this, innumerable evidences have presented themselves both in ancient and modern times. Within the period of authentic history several small islands have been known to emerge from the depths of the Gulf of Santorin, in the Grecian Archipelago. Nearly two centuries before the Christian era the small island of Palaia Kameni made its appearance; and in the year 1573 the Little Kameni was thrown up, amidst a cloud of vapour and the discharge of pumice stone. In 1707-9 another island, the result of submarine volcanic action, suddenly made its appearance, called the New Kameni, which still sends forth sulphureous vapours. There is an instance, mentioned by Kircher, of an island connected with the Azores, which was thrown up in 1538; and another in 1587, when an earthquake agitated the island of St. George; and near its shores arose eighteen small islands. There are instances where islands, after suddenly rising into existence, have begun to subside, and then gradually disappeared, or remained as shoals just below the surface of the water. Of these temporary islands, the most curious is that of Sabrina, in the neighbourhood of the Azores, which, in 1811, emerged from the deep near the coast of St. Michael. It first arose from a depth of 240 feet, and formed a dangerous shoal. Then presenting itself above the surface of the water, it continued rapidly to emerge for several days, until it rose to the height of 300 feet, and formed an island of about a mile in circumference. In its centre there was a beautiful crater, from which hot water was poured into the sea. In a few months it began gradually to subside, and in February, 1812, no trace of the island remained; but in 1813, where Sabrina once stood, there was a depth of 500 feet. In the year 1783 an island was formed by elevation about seventy miles from Cape Reykiavik in Iceland. It consisted of lofty cliffs, which emitted smoke and fire, with immense quantities of pumice, that covered the sea for above a hundred miles around. The king of Denmark laid claim to this newly-formed territory, and called it 'New Island;' but before the expiration of a year it made its disappearance, leaving nothing but a rocky reef to denote the spot where it formerly stood.

The formation of many islands, which still remain to attest their volcanic origin, is within the records of authenticated history, while others are standing memorials of the many changes and convulsions

which have marked the different superficies of the globe for countless ages before history commenced its annals, or the wonderful phenomena of nature had any intelligent witness. In the great Indian and Pacific oceans these volcanic operations have been constantly at work; and islands have been thus formed where the great ocean had rolled for ages uncontrolled. Barren Island, in the Indian Ocean, has been considered as one of the most remarkable volcanic formations now in existence. It is about six leagues in circumference, and emits, from a central cone about 1800 feet high, showers of red-hot stones of three or four tons in weight, which are thrown to a distance of many hundred feet beyond the range of the island. The surrounding sea appears of unfathomable depth. In 1806 a new island arose, among the Aleutian group of the North Pacific, about four miles in circumference, which has remained immovable ever since; and in 1814 another isle made its appearance in the same neighbourhood, which, after rising 3000 feet in height, slightly subsided, and has ever since remained firmly fixed as one of the Aleutian group of islands; all of which, beyond the possibility of doubt, have originally emerged from the bosom of the ocean, though perhaps for ages before the records of history.

ISMAELITES, or ISMAELIANS, were originally a branch of the Shiites, or followers of Ali ben Abi Taleb. Djafar Madeck, the sixth Imaum in a direct line from Ali, having lost his elder son Ismael, appointed his younger son Mousa to be his successor. This caused a schism among the Shiites in the second century of the Hegira. Those who contended that the office of Imaum ought to have descended to the posterity of Ismael, and not to his younger brother, were called Ismaelites. They established two powerful dynasties, one in Egypt, and another in the Irak Ajemi of Persia. The Ismaelites of Persia, Syria, and Arabia, had frequent wars against the Abbasside caliphs and the other Sunnee Mussulmans, until the dynasty of Casbin was overthrown by the Tartars about the middle of the thirteenth century. After that time the Ismaelites became scattered through Asia, maintaining their tenets and observing their rites in concealment and obscurity.

ISMAL, a town of Bessarabia, belonging to Russia, with a population of 25,000. It is strongly fortified, and under the Turks it had numerous mosques, bazaars, and large dwellings, but it has never regained importance since it was taken in 1790, after a long siege, and given over to military execution by the Russian general Suwarrow. The horrors of this famous siege have been described by Byron in his 'Don Juan.' [BESSARABIA.]

ISMAILA, a town in Lower Egypt, S.E. of Cairo, and situated about half-way across the Isthmus of Suez. It clusters upon the north shore of Lake Timsah, at the junction-point of the fresh-water

canal from Cairo and Zagazy with the grand ship canal, before the latter bends southwards to Suez. Travellers describe it as a busy and picturesque little place, with a church, mosque, hotel, shops, bazaars, and several handsome edifices. It owes its prosperity, and almost its existence, to the canal operations conducted by M. de Lesseps and the Suez Canal Company, and designed to unite the Red Sea with the Mediterranean. The fresh-water canal runs in front of it, and is bordered by trees and shrubs, making Ismaila quite an oasis in the desert.

ISNARDIA, a genus of plants belonging to the natural order *Onagraceæ*. There is one British species of this genus, *I. palustris*. *I. alternifolia* is a native of Virginia and Carolina, in marshy places. The root is used as an emetic.

ISOCARDIA, a genus of bivalve shells, or conchifers, placed by Linnæus under the form *Chama*, and by Brugnière among the *Cardita*. Lamarck places Isocardia as the last of the genera of his *Cardiacées*, separating it from *Chama*, as Mr. G. B. Sowerby thinks with good reason ('Genera of Recent Fossil Shells'). M. de Blainville alters the term into *Isocardium*, and inserts it as a genus between *Tridacna* and *Trigonia*, among his *Camacés*. M. Rang retains it in the same family, but restores Lamarck's original termination of the name, and places it between *Caprina* and *Tridacna*. Its true place is now (1866) acknowledged by conchologists to be in the class CONCHIFERA, as a genus belonging to the family *Cyprinidæ*.

The species are limited in number, and belong to the seas of Europe, India, and Australia. Example, *Isocardia Cor.* Europe.

Fossil *Isocardia* occur in the London Clay, in the Crag, and in the Tertiary Beds of Europe and America.

ISOCHROMATIC LINES are those coloured rings which appear when a pencil of polarized light is transmitted along the axis of a crystal, as mica or nitre, and is received in the eye after passing through a plate of tourmaline.

ISOCHRONOUS, ISOCHRONISM (*isos*, 'equal,' *χρόνος*, 'time'). Vibrations or oscillations which are performed in equal times are called isochronous; and isochronism is the name given to a remarkable property of all systems which are in equilibrium, namely, that when slight disturbance, be the same more or less, is given, the oscillations which take place are all performed in the same time, or so nearly in the same time, that any acceleration or retardation is totally imperceptible. Thus, when a pendulum is allowed to vibrate till it rests, it will be found that there is no perceptible difference between the vibrations of longer and shorter extent; of which any reader may satisfy himself by attaching a weight to a string, and observing the vibrations. But a still better proof may be found in a musical string. The finest ear cannot detect any difference between the pitch of a note made by a smart blow on the key of a pianoforte and that made by a gentle one; yet a very small difference in the number of oscillations per second would be perceptible, and the amount of disturbance from the position of equilibrium is twenty or thirty times greater in the first case than in the second.

When, under two different circumstances, the longer space is described in the same time as the

shorter, it must be that the force acting in the first case is greater than that in the second; and it is sufficiently known from experience that, the more a system at rest is disturbed, the greater is the effort which it makes to return. But, in order that there may be isochronism, it is not sufficient that the effort to return should increase with the amount of disturbance, but the increase must take place according to one particular law. This law is as follows:—The force of restitution must be always proportional to the disturbance, so that, whatever force begins to act when the disturbance is *a*, twice as much acts when the disturbance is twice *a*; and so on for all proportions. That this law does prevail when the disturbance is not great, either absolutely, or so nearly that its error is extremely small, may be proved both by theory and experiment.

ISOCRATES, one of the Greek orators commonly called the Ten, was born at Athens, 436 B.C. He studied rhetoric under Pródicus, Gorgias, Tisias, and Thérámenes, and became a master of his art. A certain timidity and feebleness in his delivery prevented him from speaking in public. He taught rhetoric both at Chios and at Athens, and his school was attended by numerous disciples, among whom were Xenophon, Ephorus, and Theopompus. Isæus, Demosthenes, and others, are said to have studied under him. The orations of Isocrates were either sent to the persons to whom they were addressed for their private perusal, or they were intrusted to others to deliver in public. He is said to have delivered only one himself. Isocrates treated of great moral and political questions; his views are distinguished by a regard for virtue, and an aversion to all meanness and injustice. He was a friend of peace; he repeatedly exhorted the Greeks to concord among themselves, and to turn their arms against their common enemy Persia. In his 'Panegyric Oration' (published about B.C. 379), which he wrote in the time of the Lacedæmonian ascendancy, he exhorted the Lacedæmonians and Athenians to vie with each other in a noble emulation, and to unite their forces in an expedition against Asia. He addressed Philip of Macedon in a similar strain after his peace with Athens (B.C. 346), exhorting him to reconcile the states of Greece, and to unite their forces against Persia. He displayed considerable courage on several occasions, as when he showed his sympathy for Theramenes, who had been condemned by the thirty tyrants. On the news of the battle of Chæronea, he refused to take food for several days, and thus closed his long career at ninety-eight years of age, B.C. 338.

There are extant eight orations of Isocrates of the class called judicial, or forensic, which are valuable for the subject-matter. Three of the orations of Isocrates—to Demonicus, to Nicoteles, and the oration entitled Nicoteles—belong to the prænetic or hortatory class, and the first two partake in some degree of the epistolary style. The 'Panathenæicus' is a panegyric of Athens, which he wrote when he was ninety-four years of age. ('Panath.,' c. 1.)

The style of Isocrates is perspicuous, but highly laboured, and somewhat diffuse. In Cicero's opinion it was he who first gave to prose writing its due rhythm. Dionysius has thus briefly summed up his

comparison between Lysias and Isocrates. 'As to the charm of composition, Lysias is superior to Isocrates in the same kind that a naturally handsome person is to one made so by art: the composition of Lysias pleases naturally; that of Isocrates aims at pleasing.' Twenty-one of his orations have come down to us, together with a few epistles, probably not genuine. The best edition of the Greek text is by Bekker. Isocrates was translated into English by Richard Sadleir, London, folio (no date); by Dinsdale, London 1752, 8vo.; and by Gillies, together with the 'Orations of Lysias,' London, 1778, 4to.

ISOCRINITES, a genus of *Crinoidea* (Goldfuss).

ISOETES, a cryptogamic genus of plants, belonging to the order *Lycopodiaceæ*. The species of *Isoetes* grow at the bottoms of ponds and lakes, and are said to afford excellent food for fish. They are called Quillworts from the rush or quill-like appearance of the leaves. *I. lacustris*, quillwort, is found in Great Britain, at the bottom of lakes and ponds in hilly districts. The structure of the fructification of this plant, and other species of the genus, is only imperfectly understood. It is on this account referred to *Marsilleaceæ* by some authors, and made to form an independent order by others. Lindley refers it to *Lycopodiaceæ*.

ISOMERISM. (Greek, *isos*, 'equal,' and *μερος*, 'part'.) Substances which contain the same elements in the same ratio, and yet possess physical and chemical properties quite distinct, are classed as *isomeric*, *polymeric*, and *metameric* substances. A striking instance of this relation between a number of compounds is seen in cyanic acid and its *isomers*.

Isomeric bodies are those which contain the same absolute and relative number of atoms of the same elements, and have consequently the same atomic weight.

Polymeric substances are those which contain the same relative but not the same absolute number of atoms of the same elements, and whose atomic weights are consequently unlike. Several carburets of hydrogen offer examples of polymerism.

Metameric substances are those which, while they contain the same absolute and the same relative number of atoms of the same elements, yet constitute substances belonging to an entirely different class of bodies, or a different order of chemical compounds. There are several substances of this kind.

ISOMORPHISM (*isos* and *morphe*). This term, employed in chemistry and crystallography, strictly signifies similarity of form, though chemists restrict it to such bodies as are not only similar in crystalline form, but also in chemical composition. Thus, diamonds, magnetic oxide of iron, and alum all possess the same crystalline form, that of the octohedron; yet they are not regarded as isomorphous, because they do not possess the same constituents. On the other hand, spinelle-ruby, magnetic oxide of iron, and chrome iron ore are termed isomorphous, because they not only crystallize in the same form, but resemble each other in their composition. The best work of reference on isomorphous groups and the doctrine of *dimorphism*, is Miller's 'Chemical Physics.' [ISONARDIA.]

ISONANDRA (Gr. *isos*, 'equal,' and *aner*), a genus which includes the Gutta-percha tree (*J.*

gutta), a forest giant of the Indian Archipelago, which attains a height of seventy feet, and a girth of three feet. The milky fluid which it yields is the well-known gutta-percha, and each tree affords about twenty pounds.

ISOPODA (*isos*, 'equal,' and *πους*, 'a foot'), Latreille's name for the fifth order of crustaceans. Some of these crustaceans are aquatic in their habits, others are terrestrial, and many of the aquatic species are parasitic. The feet are always fourteen in number, unguiculated, and without any vesicular appendage at their base. The two anterior feet are not annexed to the head, but, like the succeeding ones, depend upon their particular segment. The under part of the tail is furnished with appendages which are very apparent, and in the form of leaflets, or vesicular purses. Of these, the first two, or external ones, ordinarily cover the others, either totally or in great part. The body is generally flattened, and wider than it is thick. The mouth is composed of the same pieces as in the crustaceans which precede it in M. Latreille's system, but in the order before us those which answer to the two superior jaw-feet in the *Decapods* present more the appearance of a lower lip terminated by two palpi. Two of the antennæ, the mesial ones, are almost obliterated in the last genera of this order, which are all terrestrial, and differ besides from the other by their respiratory organs. The male sexual organs are pointed out most frequently by the presence of linear or filiform appendages, and sometimes by hooks placed at the internal origin of the first subcaudal laminæ. The females carry their eggs under the breast, either between the scales or in a membranous pouch, or sac, that opens to afford a passage for their young, which are hatched with the form and parts proper to the species, and only cast their skin as they increase in size. The greater number live in the waters. Those which are terrestrial have need, like other crustaceans that live out of water, of a certain degree of atmospheric humidity, in order that respiration may be carried on, and that their branchiæ may be in a fit state for performing this function. Latreille divides the Isopods as follows:—

1. *Epicarides*. Parasitical. Genus, *Bopyrus*.

2. *Cymothoada*. With four setaceous antennæ. Genera—*Serolis*, according to Dr. Buckland, allied to the extinct *Trilobites*, *Cymothoa*, *Ichthyophilus*, *Canolira*, *Aga*, *Rocinella*, *Conilira*, *Synodus*, *Cirolana*, *Nelocira*, *Euridice*, *Limnoria*.

3. *Sphæromides*. Genera—*Zuzara*, *Sphæroma*, *Næsa*, *Cilicæa*, *Cymodocea*, *Dynamene*, *Anthura*.

4. *Idoteidae*. Genera—*Idotea*, *Stenosoma*, *Arc-turus*.

5. *Asellota*. Genera—*Asellus*, *Oniscoda*, *Jæra*.

6. *Oniscidae*. Genera—*Ligia*, *Tylos*, *Philosocia*, *Oniscus*, *Porcellio*, *Armadillo*.

ISOPYRE, a mineral which occurs in granite. It is brittle, grayish black, translucent, and slightly magnetic. It consists of silica, alumina, lime, peroxide of iron, and oxide of copper, and it is found in compact masses in the granite of St. Just, near Penzance, in Cornwall.

ISOCELES (*isos*, 'equal,' *skelos*, 'leg'), a term applied to a triangle of which two sides, or legs, are equal.

ISOTELUS, a genus of fossil Crustaceæ (*Trilobites*) from the Silurian strata, especially of North America. (Green.)

ISOTHERMAL LINES (Greek, *isos*, 'equal,' and *therme*, 'heat'), are imaginary curves traced on the surface of the earth so that each may pass through a series of points at which the mean annual temperature of the air is the same. The situations of such points were first determined by M. Humboldt from the registers of observed temperatures in Europe, and from the numerous observations made by himself and other travellers in different regions of the world. The mean annual temperatures of places remain nearly the same, but they decrease in going from the equatorial regions towards either geographical pole. At the level of the sea the value of the mean annual temperature is expressed by $M + E \cos 2L$; where L is the latitude of the place, M is the mean temperature on the parallel of 45° , and $M - E$ is that at the equator.

In the northern hemisphere, as we proceed eastward and westward from the meridians of Greenwich or Paris, it is found that the mean temperature on any parallel of latitude becomes continually less, and the severity of the winter greater than in this part of the world; and M. Humboldt found that between the parallels of $28^\circ 25' N.$ and $41^\circ 53' N.$ the difference between the latitudes of a place in Europe and a place in North America, having the same mean temperature, is about 7° .

The period during which a traveller remains in any one place will seldom allow him to make a sufficient number of observations for determining its mean annual temperature by the process above mentioned; and therefore it may be useful to know that, according to Humboldt, the mean temperatures for the months of October and April are very nearly equal to the annual mean temperature; also that the half sum of the temperatures at sunrise and at 2 P.M. is nearly equal to the mean temperature for the day. It may be proper to remark also that travellers, in making observations relating to temperature, should be careful to place their thermometers at some distance above the surface of the ground, and in situations where they may be unaffected by the reflection or radiation of heat from buildings, or from terrestrial particles in the atmosphere. The very high temperatures which have been occasionally observed in sandy deserts are probably owing in part to the latter circumstance.

The isothermal line of 32° passes about 4° southward of Nain, a Moravian settlement on the coast of Labrador; and continuing eastward through a point about $1^\circ N.$ of Umea in Sweden, it there makes a remarkable inflection. After ascending as high as North Cape in Lapland, it abruptly returns southward, and attains its lowest limit in the eastern parts of Asia. Proceeding westward from Labrador, the curve descends towards the south, and crosses the lower extremity of Hudson's Bay, from whence it again tends northwards to the great Slave Lake. The positions of the other curves seem to be influenced in some measure by that which has been just mentioned. In their progress from the western coast of Europe to the eastern coast of America they incline towards the terrestrial equator, yet so that the southern curves approach very near to parallelism with that great circle of the earth. At about 10°

eastward of the meridian of Greenwich the curves have their convexities turned northwards; and farther eastward they descend towards the equator. The isothermal line of 54.5° has been traced nearly round the earth: commencing at the mouth of the Columbia, on the western coast of North America, it passes near the city of Washington with its convexity towards the south; and, after crossing the Atlantic, it runs through Bordeaux, from whence it continues to the city of Pekin, at which place it again becomes convex towards the equator. From the observations of Sir Edward Parry and Sir John Franklin, it appears that there are in the northern hemisphere two poles of maximum cold; both, conformably to the determination of Sir D. Brewster, are on the 80th degree of N. lat.

But in every country the mean temperature varies with the height of the place above the level of the sea; and Mr. Atkinson, in the 'Memoirs of the Royal Astronomical Society,' from a comparison of many observations, makes the diminution equal to 1° Fahr. for every 251.5 feet. He has also shown that the differences of temperature between summer and winter begin to diminish at the height of about 21,000 feet above the surface of the earth.

The curves formed by connecting, on the isothermal lines, points at which the mean temperature of summer is the same, are called *isothermal lines*; and those formed by connecting points at which the mean winter temperature is the same are called *isothermal lines*: both these systems of lines deviate more than the isothermal lines from the parallels of terrestrial latitude. Curve lines connecting points on the ground at which the mean temperatures of the soil are equal, are called *isogeothermal lines*; and according to Sir D. Brewster, these are always parallel to the isothermal lines.

It was supposed that the mean temperature of the southern hemisphere was much lower than that of the northern, but recent observations afford good reason to believe that there is little difference between the mean annual temperatures of places similarly situated in the two hemispheres.

M. Humboldt considered the mean annual temperature at the equator, at the level of the sea, to be equal to 81.4° Fahr.: but Mr. Atkinson ('Memoirs of the Royal Astronomical Society,') ascertained that the mean temperature is there at least equal to 84.5° .

Of the point or points of maximum cold in the southern hemisphere, we as yet know positively nothing.

It is found, on boring into the earth, that the temperature increases at the rate of 1° (Fahr.) for every 50 feet in depth. In the arctic regions the temperature of the ocean increases, but between the tropics it is found to decrease, with the depth. At certain distances below the surface of the ground, which in Europe is between 50 and 100 feet, the temperature is found to be invariable. (Johnston's *Physical Atlas*; Humboldt's *Cosmos*, &c.)

ISPAHAN. [PERSIA.]

ISRAEL, TRIBES OF. [JUDEA.]

ISSOIRE. [PUY-DE-DÔME.]

ISSOUDUN. [INDRE.]

ISSUE is an ulcer artificially formed for the purpose of maintaining a constant purulent discharge from the body. It is usually made by placing one

or more beads or peas on an incision through the integuments in one of the limbs, or in the neighbourhood of a diseased part, and there retaining them by adhesive plaster, so as to prevent the wound from healing, and keep it in a constant state of suppuration. Other issues are made by rubbing caustic potash, or potash and quicklime, on a part of the skin till it is destroyed and sloughs, and by keeping open the ulcer thus formed, either with peas or very stimulant dressings. Setons are another form of issue, made by passing a broad flat needle beneath a portion of the skin, and retaining in the passage thus formed either a skein of silk or a flat band of caoutchouc. The moxa and the actual cautery are also sometimes employed with the same view.

Issues are sometimes had recourse to in order to restore an habitual discharge which has been checked by the cure of any chronic local disease, and the cessation of which has seemed to give rise to congestion of the head or of any internal organ. But the principal value of issues is as counter-irritants, by establishing a disease which is of itself unimportant in the neighbourhood of one which by its situation is more serious; and hence they are amongst the most important means in the cure of chronic inflammations of many internal organs, and especially of those of the joints and of the spine.

ISSUE. (Law.) [PLEADING.]

ISSUE PEAS are round bodies employed for the purpose of maintaining irritation in a wound of the skin which is called an issue. It is a matter of indifference of what substance the peas are composed, so long as they do not introduce poisonous matters into the wound. The common garden pea is frequently used. It is, however, more common to use the young unripe fruits of the common orange. The fruits are dried and afterwards turned in a lathe before they are used as issue peas. The unripe oranges, dried, are sold under the name of *orangettes* or *Curaçoa oranges*. The root-stock of the *Iris Florentina* is also formed into peas and used for keeping up the discharge from issues.

ISTHMIAN GAMES were one of the four great national festivals of Greece, the others being the Olympian, Pythian, and Nemean. They were celebrated under the presidency of the Corinthians, near Corinth, on the isthmus which connects Peloponnesus with the continent, and were celebrated at intervals of three or four years—authorities being at variance on this point—so that each year had its solemnity. The crowns for the victors were of pine leaves. [OLYMPIAN GAMES.]

ISTIU'RUS (Gr. *iston*, 'a sail,' and *oura*, 'a tail'), a genus of Saurian reptiles, of the family *Iguanida*.

ISTRES. [BOUCHES-DU-RHÔNE.]

ISTRIA. [ILLYRIA.]

ITAKA WOOD, the timber of a tree indigenous to British Guiana, *Mackærium Schomburgkii*. It affords a beautifully mottled wood much employed in cabinet work.

ITALY (Lat. and Italian, *Italia*; French, *Italie*; German, *Italien*), one of the most fertile and extensive countries in the south of Europe, though formerly separated into numerous subdivisions, is evidently marked out by nature for one great whole. It consists partly of islands and partly of mainland.

The continental portion extends from 47° to 37° N. lat., and from $7^{\circ} 21'$ to $13^{\circ} 30'$ E. long. On the W. and S. its shores are washed by the Mediterranean. On the E. it is bounded by the Adriatic; on the N., N.E., and N.W., the lofty chain of the Alps, including the Pennine, Rhetian, and Carnic systems, separate it from the rest of Europe by an almost impassable barrier. Towards the N.E., however, its boundary is more exactly defined by the River Isonzo, which, rising in the Carnic Alps, flows onward to the Gulf of Trieste, at the head of the Adriatic. Its extreme length, as thus developed, is about 590 miles; its breadth, in the N., where it is greatest, 311 miles; but it so rapidly diminishes as it shoots towards the south, that while in the centre it is only 150 miles wide, at its narrowest southern point it does not exceed 15 miles.

The whole of Italy, with the exception of the Papal territory and Venetia, is now united into one kingdom under the rule of a constitutional sovereign; but previous to the great war of 1859 it consisted of several independent states, whose names it seems desirable to preserve, for the convenience of reference. These divisions were—

1. Austrian Italy, or Lombardo-Venetian kingdom, including Lombardy, now belonging to the kingdom of Italy, and Venetia, still under the rule of the Hapsburgs. [LOMBARDY.]
2. Kingdom of Sardinia, including Piedmont, Sardinia, and Savoy, the latter now belonging to France, being the price which Italy paid for the assistance rendered by the Emperor Napoleon in her struggle with Austria.
3. Kingdom of Naples and Sicily, now included in united Italy.
4. The Papal States, restricted in area since the war of 1860.
5. Grand Duchy of Tuscany, including Lucca.
6. Duchy of Parma.
7. Duchy of Modena.
8. Republic of San Marino. And
9. Principality of Monaco.

The latter, a small and insignificant state, still preserves a nominal independence.

The following are the leading divisions and principal towns of Modern Italy:—

Chief Divisions.	Cities and Towns.
Piedmont, ...	Turin, Asti, Alessandria, Novara, Cuneo, Genoa, Port Maurice, Susa.
Lombardy, ...	Milan, Pavia, Cremona, Brescia, Bergamo, Como, Sondrio.
Æmilia, ...	Parma, Piacenza, Modena, Carrara, Reggio, Bologna, Ferrara, Ravenna, Forlì.
The Marshes, ...	Ancona, Ascoli, Urbino, Pisano, Maurata.
Umbria, ...	Perugia.
Tuscany, ...	Florence, Leghorn, Pisa, Sienna, Arezzo, Lucca.
Neapolitan Territory, ...	Naples, Pozzuoli, Castellamare, Gaeta, Reggio, Taranto, Foggia.
Island of Sicily, ...	Palermo, Messina, Catania, Marsala, Siragusa, Girgenti.
Island of Sardinia, ...	Cagliari, Sassari, Oristano.

The Pontifical Territory includes the cities and towns of Rome, Ostia, Civita Vecchia, Viterbo, and Tivoli.

Venetia—Venice, Padua, Verona, Vicenza, Mantua, Peschiera, Legnago, Chioggia, and Treviso.

Physical Features.—Every schoolboy is familiar with the old comparison of the Italian peninsula to a boot; a comparison which is far more accurate than most of these fanciful similitudes. The broadest, or northern portion, forms the mouth; the central portion, the leg; and the southern, the foot. This southern portion is divided into two small peninsulas, which respectively terminate in the capes of Spartivento and Di Leuca; and between these two notable headlands lies the Gulf of Tarento (anciently Tarentum). Cape Nau, or Colonne, projects on the western side of the entrance to the Tarentine Gulf. Cape Gargano, on the promontory of San Angelo, is thrown out into the waters of the Adriatic, on the eastern side of the peninsula; while on the western coast project the capes of Palinuro, Campanello, Circello, Monte d'Argenturo, and others, famed in song, legend, and history.

Numerous islands stud the Italian seas. Of these the largest are—Corsica, celebrated for its romantic scenery and the ardent spirit of its inhabitants, no less than for the birth of the great Napoleon; it belongs to France: Sardinia, formerly an appanage of the House of Savoy, whose natural resources are considerable, and have only been imperfectly developed: and Sicily, off the Neapolitan coast, one of the fairest and richest of the isles of Europe. Less important are the Lipari Islands, north of Sicily; Malta and Gozo, belonging to England, midway between Gibraltar and the peninsula; Elba, once celebrated for its iron mines; and various groups of islets in the Adriatic. The total area of Italy, including these outlying portions, but without Corsica, is 122,867 square miles, a magnitude which is about one-seventeenth part greater than the United Kingdom of Great Britain and Ireland.

In the N. and S. Italy is a mountainous country; in the centre it spreads into vast levels, and an extensive plain also lies between the Adriatic, the Alps, and the Northern Apennines. The Apennines divide Italy into two distinct regions: one, lying to the N., is the plain already spoken of, and chiefly occupied by the basin of the Po and its numerous affluents; the other, which is the real peninsula, stretches in a south-eastern direction for above 500 miles. The Apennines and their lower ranges form the backbone of this peninsula, extending its whole length, and terminating on the coast of the Strait of Messina. On each side lies a narrow belt of level ground, watered on the W. by some important rivers—the Arno, the Tiber, the Garigliano, and the Volturno.

General View of the Surface.—It will assist the reader to form a correct conception of the features of the country, if he supposes himself placed in a balloon at a moderate height, and proceeding slowly from N. to S. At the outset of his aerial journey he will see beneath him the huge bulk and snowy pinnacles of the great Alpine chains, spreading in a vast semicircle of rock, avalanche, and glacier from the head of the Gulf of Trieste, on the E., to the extremity of the Gulf of Genoa, on the W. These

chains include the Carnic Alps, N. of Venetia; the Rhetian Alps, north of Lombardy; the Lepontine, and the Pennine Alps, to the N.; the Graia, Cottian, and Maritime Alps, to the W. of Piedmont. Their crests rise above the limit of perpetual snow, and their flanks, as they descend into the fertile plain of Lombardy, exhibit every charm of scenery and every variety of vegetation. Formidable, however, and apparently insuperable as such a barrier appears, it cannot daunt the enterprise of men, and the 'iron horse' will shortly break through it. A railway, to be completed in 1875, is being carried across Mount St. Gothard, and another, to be opened in 1871, is slowly ascending the difficult acclivities of Mont Cenis.

Now before the aeronaut spreads the vast plain of Lombardy, with a gradual slope towards the head of the Adriatic, and encircled by a network of fertilizing waters—the Po and its numerous tributary streams. The lower part of the plain is almost a perfect level, smiling with crops and vineyards, rich in luxurious pastures and mulberry groves, which are largely cultivated for the sake of the silkworm—the most fertile and populous portion of the Italian peninsula. The mountain-chains which encircle it sweep upwards with a steep acclivity, and embosom among their spurs numerous fair and tranquil valleys. Here are situated the beautiful Italian lakes, Guarda, Como, and Maggiore, each distinguished by a peculiar loveliness of its own.

To the W. lies Piedmont (*i.e.*, at the foot, *pied*, of the mountain, *mont*), a finely varied and fertile plain, intersected by the Po, which rises in Monte Viso, and traverses it from W. to E., throwing off numerous arms, to the great facility of intercommunication and the infinite advantage of the agriculturist.

Keeping along the western side of the pine-clad Apennines, we find an extensive undulating district, stretching along the shores of the Mediterranean for nearly 200 miles, from Pisa to the ancient stronghold of Terracina, and varying in breadth from ten to upwards of thirty miles. Except in the immediate vicinity of Pisa and Leghorn, this considerable region is characterized by desolation and decay, and too often infested by roving bands of robbers. The Tuscan portion of this unpleasant tract is known as the *Maremma*, and unfavourably celebrated for the pestilence which, from April to October, broods over its swamps and valleys. The whole region is, however, more or less subject to malaria for a considerable portion of the year. Along the borders of the Apennines exist very different conditions. The scenery is full of nooks and corners which might charm an artist; the population is industrious; the earth offers abundant treasures of marble and copper, and the olive is extensively cultivated.

In the neighbourhood of Rome the coast district forms the well-known Campagna di Roma, the greater portion of which is cursed with malaria, and hence has been abandoned by men as well as neglected by nature. It is equally bare of trees and human habitations. Adjoining its south-eastern extremity spread the Pontine Marshes, which extend for 22 miles along the coast, and from 6 to 12 miles inland. They have been partially drained, and are capable of extensive cultivation, but their extreme unhealthiness deters the agriculturist from attempting their reclamation.

Further to the southward we pass into a sunlit land—the Neapolitan Provinces, rich in the choicest gifts of nature, where, with little labour, the bountiful soil abundantly yields the grape, the olive, Indian corn, and every variety of legumes and fruit. Scarcely a spot which does not present some picturesque and romantic landscape; scarcely a spot, it may be added, which is not hallowed by some classical or legendary association. Here, too, rise numerous volcanic peaks, and, conspicuous among all, towers the famous Vesuvius, raising its crest of fire above the beautiful Bay of Naples and the sites of the ruined cities of Pompeii and Herculaneum. With Sicily, the south-western portions form the earthquake region of Italy, which has been frequently devastated by shocks of appalling violence.

Traversing now the eastern side of the Apennines, we observe that a considerable plain—the Capitanata, or Terra de la Puglia—stretches from the neighbourhood of Otranto to the bold bluff promontory of San Angelo. Its southern part is dry, barren, and generally treeless; northward, it improves in character, and furnishes some extensive pastures.

Still further north we come to the old historic city of Ravenna, surrounded by ancient woodland, which Byron, Boccaccio, and Dante have celebrated in immortal song. Of old it supplied the Romans, and, at a later time, the Venetians, with timber for their fleets. The forest extends about 28 miles along the shore, and inland from 1 to 3 miles.

'Various the trees and passing foliage there,
Wild pear, and oak, and dusky juniper,
With briony between in trails of white,
And ivy, with the suckle's streaky light:
And still the pine, long-haired, and dark, and tall,
In lordly right, predominant o'er all.'

Byron, who spent two years at Ravenna, has referred to the changes which this part of the Italian coast has undergone since the pre-historic age:—

'Sweet hour of twilight! in the solitude
Of the pine forest, and the silent shore,
Which bounds Ravenna's immemorial wood,
Rooted where once the Adrian wave flow'd o'er,
To where the last Cæsarian fortress stood—
Evergreen forest!'

But our aerial voyage terminates at Venice, 'a glorious city in the sea,' situated on a number of islands that lie in the midst of extensive lagoons, and are connected by many bridges. The Venetian territory, as at present constituted, lies between the Tyrol and the Adriatic, and is separated from the Italian kingdom by the lower course of the Po and the stream of the Mincio, one of its principal affluents. The territory thus inclosed covers about 9500 square miles, whose surface is finely contrasted: fertile plains, clustering groves, beautiful vales, and Alpine spurs combining to form a richly attractive picture. Besides the Mincio and the Po, it is watered by the Adige, the Brenta, the Piave, and the Tagliamento, which are linked together by an admirable system of canals. The whole of the maritime region, and a portion of the interior, constituted the celebrated republic of Venice, which was founded in the fifth century by the fugitives driven to the littoral marshes by the furious irruptions of Attila.

Hydrography.—The principal Italian rivers are the Po, the Adige, the Arno, and the Tiber. Of these, the only one important in volume or extent is

the Po—the classic Eridanus—which is capable of navigation throughout its whole course, though subject to frequent changes in the rapidity of its current, when its numerous tributaries are swollen by violent rains, or the melting of the mountain snow. The father, or king of rivers, as the Italians euphoniously call it, rises in Monte Viso, one of the Cottian Alps, and flows rapidly eastward, as a mountain torrent, until it develops at Lombriasco into a majestic stream. Turning to the north it passes Turin, and taking an easterly direction, reaches the borders of Lombardy, and receives the Ticino. It then gladdens Piacenza and Cremona with its waters, forms the old frontier of the so-called Papal States, throws off several branches, and finally, dividing into two principal arms, the Po-di-Maestra, and the Po-di-Goro, enters the Adriatic by two mouths, about 12 miles distant from each other. Its direct course is 270 miles, including windings, about 450 miles. It carries down with it a large amount of sediment, but is well stocked with fish, especially shad, salmon, and sturgeon.

The Tiber (anc. *Tiberis*; Ital. *Tevere*) rises in the Apennines, in the province of Florence; flows first S., then S.S.E.; crosses the Papal States; traverses immortal Rome, with whose glories it is inseparably associated; flows S.W., and, separating into two branches, the Fiumano and the Fiumara, falls into the Tyrrhene Sea by two mouths: length, about 240 miles. Its waters are always loaded with a yellowish mud, whence Horace terms it 'flavus Tiber,' the tawny Tiber.

The Adige (anc. *Athesis* or *Atisius*) rises in the Rhetian Alps, about 46° 30' N. lat., and, after a sinuous course of about 180 miles, chiefly S. and W., falls into the Adriatic at 45° 10' N. lat., and 12° 20' E. long., entering the sea with the Po by a delta common to both. Its principal affluents are the Eisack, the Novi, and the Avisio.

The Arno (anc. *Arnus*) is a Tuscan river, and one of the largest in Italy. Its sources lie in Monte Fallarina, among the Apennines. Its general direction is westward. After passing through Florence it becomes navigable, and about seven miles below Pisa falls into the Mediterranean, after a course of about 155 miles.

The Ambrone, in Tuscany, is a considerable stream; the Garigliano and Volturno are of less importance.

The largest lakes are those of Maggiore, Como, and Garda.

The Lago Maggiore, or Verbano, in Tessin, Piedmont, and Lombardy, is about 40 miles long, with a maximum breadth of 5½ miles, and a mean breadth of 2 miles. Depth, 2625 feet; height above the sea-level, 638 feet. It is surrounded by landscapes of exquisite beauty, in which the Alpine heights form a notable feature.

But far lovelier, richer, and more varied is the Lake of Como, which lies at the base of the Lepontine and Rhetian Alps, 700 feet above sea-level. It is mainly formed by the river Adda, and is divided into three basins by projecting spurs of land. It is altogether about 15 miles in length, and its general breadth does not exceed 2 miles. Throughout its whole extent the banks are formed of steep and well-wooded mountains, 3000 to 4000 feet in height.

The Lago di Garda (or Benaco) is another beautiful expanse of inland water, 33 miles long, and 3 to 11 broad, and 213 feet above the sea-level. It receives the Sarca, and is drained by the Mincio, which issues from its south-eastern extremity, near the stronghold of Peschiera. It teems with fish. Greatest depth, 902 feet.

In southern Italy lie some lakes, or rather lakelets, of less extent, but generally of infinite loveliness, such as the Lago di Albura, and the lakes of Perugia and Fusino.

Mountains.—These are divided into two great systems—the Alpine and the Apennine. The former may more properly be considered under the head of SWITZERLAND, though some of the principal peaks look down upon the fair Italian plains. The Apennines run down the whole length of the Peninsula, and though attaining no very remarkable elevation, are so broken in outline, and so richly wooded, as to present some most delightful and romantic points of scenery. Their chain chiefly consists of limestone, which furnishes admirable building materials, and also marble of excellent quality; the pure white Carrara marble being especially prized by sculptors. Granite occurs in Calabria, at the southern extremity of the range. Among the principal heights may be enumerated:—

Monte Vellino, 7851 feet; Termenillo Grande, 7212 feet; Monte Amaro, 9110 feet; Monte Vettore, 8020 feet; Monte Prùre, 7847 feet; Monte della Sitilla, 7260 feet; and Monte Maceria della Morte, 6690 feet.

The principal *Volcanic Mountains* are those of Vesuvius, Etna (in Sicily), and Stromboli (in the Lipari Isles). Of the first-named, which rises to 3792 feet in height, a traveller furnishes the following description:—

'Vesuvius,' he says, 'has been prodigiously higher than it now is, for the Monte Somma, a peak about 800 yards north of the present cone, and Ottarcina, on the south, are apparently peaks remaining of the circumference of the base of some vast ancient cone. These three remaining peaks, of which Monte Somma is the highest, belong to one mountain-base, although divided above by chasms of the vast extinct crater, and by ravines below, and the whole mountain-mass is a single independent elevation on a vast plain, and unconnected with the Apennines.'

Its flanks, towards the summit, are black and rugged with lava, ashes, and scorix, but near the base they teem with vineyards, groves, and orchards.

Mount Etna, whose eruptions have almost equalled those of Vesuvius in violence, is situated in Sicily, about 60 miles S.W. of Messina. Its loftiest peak is 10,874 feet above the sea-level, and its enormous base occupies an area of nearly 90 miles in circumference. Sulphurous vapours are continually ascending from its crater; and in the spring of 1865 a terrible explosion occurred, which caused great havoc in the surrounding country.

Stromboli (anc. *Strongyle*), is one of the Lipari Isles, about 35 miles north of the coast of Sicily. It is about 9 miles in circuit, and consists entirely of a single volcanic mountain, whose crater-summit rises about 2500 feet above the sea-level. As it is continually sending forth shafts of flame and clouds of smoke, and as its burning crest is visible for many

miles at sea, sailors have appropriately named it the Lighthouse of the Mediterranean. No actual explosion, however, has occurred since the commencement of the Christian era.

Geology.—The geological structure of Italy is necessarily connected with the comparative fertility of its various portions. The volcanic formations, by the decomposition of their lavas, yield soils of amazing fertility; but in the immediate vicinity of the Alps and the Apennines, where granite and primitive rocks abound, the country is generally barren, and tasks all the science and industry of the agriculturist in its improvement. The sedimentary rocks are of recent date. At the bottom lies the Jura limestone, stretching from the frontiers of Tuscany into the Neapolitan provinces, while in Lombardy it extends from Lago Maggiore to the coast of the Adriatic. Chalk, which lies upon the limestone, stretches in a narrow band along the western shore, from the Gulf of Genoa to the glittering headland of Cape Santa Maria di Leuca. Above this accumulate the tertiary sandstones, travertine, and marl, chiefly on the E. coast, but also developed largely in Tuscany and Piedmont. And finally, the upper crust, which continually increases, consists of alluvial and diluvial deposits, occupying the greater part of the basin of the Po.

Climate.—Generally speaking, the Italian climate is warm and dry, but it is necessarily affected by differences of elevation and position with regard to the mountains and seas. While in Naples and Sicily ice and snow are unknown, except on the lofty brow of Etna, north of the Apennines snow falls in winter, and the broad lagoons at the mouths of the rivers freeze. In Central Italy the olive, orange, and lemon flourish luxuriantly, and throughout the year the ground is mantled with verdure. In the southern provinces a tropical vegetation covers the low warm plains, such as the sugar-cane, the papyrus, the Indian fig, and the date-palm. In summer the heat is intense, and the fell breath of the sirocco frequently scorches the earth. The rains fall with great violence at particular seasons; but on the whole the atmosphere is wonderfully transparent, and the sky of that glowing and intense azure which has become proverbial. From morn till eve it remains without a cloud; darkly, deeply, beautifully blue, except when the glories of the sunset enrich it with a thousand combinations of colour, like flashes of rare jewellery—emerald, and topaz, and ruby—all fading softly and slowly into the 'clear obscure' of night.

Dr. Burgess, however, is of opinion that the Italian climate is not favourable to invalids. 'It is a mistake,' he says, 'to suppose that a warm, humid, relaxing atmosphere can benefit pulmonary disease. Cold, dry, and still air appears a more rational indication, especially for invalids born in temperate regions. The climate of Naples is the most dangerous in Italy for persons suffering from affections of the respiratory organs. Genoa, Florence, and Pisa are scarcely less prejudicial; and the two safest localities would seem to be Como and Venice.'

Natural Products.—The mineral wealth of the peninsula is extensive and varied. Tuscany possesses rich mines of lead, copper, quicksilver, cinabar, and sulphur; and the mines of Elba export large quantities of iron ore daily. Boracic acid is supplied

from the Tuscan mines to most of the European manufacturers. Its existence was first discovered in 1777, and it is now largely substituted for the borax of India. It is procured from the lagoons of Monteccevoli, which consist of a countless number of small volcanoes and springs constantly in violent action; the ground, which quakes and glows beneath the feet, is covered with crystallizations of sulphur and other minerals.

The alum pits of Tuscany afford an unfailing supply. In Southern Italy and Sicily occur extensive beds of sulphur; and Sicily exports nearly all that is consumed in Europe, producing as much as 70,000 tons annually. The salters and brine springs in the marshes afford large quantities of salt. Limestone, marble, alum, alabaster, lava, nitre, granite, are among the treasures which Italy derives from her mountain masses.

We have already hinted at the luxuriance and variety of Italian vegetation in the more fortunate districts. The plains and lower slopes of the hills bloom with the mulberry, the vine, the olive, the myrtle, the laurel, and numerous fruits and evergreens. At a greater altitude wave extensive woods of chestnut, oak, beech, pine, and the silver fir; the latter a tree highly valued by the ancients, and immortalized by Virgil—

'Hills clad with fir, to guard the hallowed bound,
Rise in the majesty of darkness round.'

The vine is of universal cultivation. The plants begin to bear fruit in the third year, and the vintage commences at the end of September. Figs, almonds, and cucumbers thrive in the south, as well as tobacco and cotton. Rice is grown in the marshy districts, and the liquorice root in the Calabrias. The best olives are those which flourish at Venapo, and are locally known as the *Sergia*; the oil which they yield is famous for its sweetness and purity.

Agriculture.—Scientific farming, in the British sense, is almost unknown in Italy, and nature steps in to supply the want by providing a genial soil and a warm climate. A very important branch of industry is the culture of the mulberry tree for raising silkworms; and the silk exported from the Lombardo-Venetian provinces alone produces an annual revenue of 5,000,000*l.* About 2,000,000 lbs. of cotton are grown in Southern Italy and Sicily every year. The corn crops are extensive, and afford an excellent grain. Not more than two-thirds, however, of the entire area of Italy is cultivated; the rest lies waste. The average value of cultivated land is 3*l.* 2*s.* per hectare, and in some parts of the northern provinces 5*l.* The annual income arising from real estate is computed at 40,320,000*l.*, but the mortgages upon this amount are very heavy.

Italy possesses at the present time 3,355,590 cows or oxen, 1,000,000 horses, mules, and asses, upwards of 40,000,000 goats, and 3,129,500 pigs. Its natural history differs but little from that of the rest of southern Europe, except that it includes among insects the asp, scorpion, and tarantula. There are 250 species of birds in Central Italy alone, and every copse and grove thrills with music. Among the wild animals found in the forests may be named the wolf, the lynx, the stag, the marmot, the badger, and the wild boar. Foxes and hares abound, and in the south of Italy the crested porcupine. The

ivers and lakes abound in fish, and on the coast are numerous important fisheries, especially the tunny, anchovy, and sardine. Goats are numerous in most districts of Italy. Throughout the country oxen are universally used for the plough, and in many parts buffaloes, though not so readily tamed. In the neighbourhood of Milan, Pavia, and Lodi immense herds of cattle are reared, and great quantities of cheese—especially that which is so well known in Europe as Parmesan—are annually produced.

Tuscany yields several kinds of wine, of a superior quality, which the poet Redi celebrated in his glowing dithyrambic of 'Bacco in Toscana.' That of Montepulciano he styles the 'king of all wines,' *d'ogni vino è il re*—it is known commercially as the Aleatico, or red muscadine, has a brilliant purple colour, and a delicious keenly aromatic flavour. The Columbano, the Trebbiano, and the Vernaccia are also highly esteemed.

Area and Population.—The new kingdom of Italy, as constituted in 1860, contains a population of 21,777,334 souls (according to the census of 1864), distributed over an area of 98,784 square miles. If Venice and the Papal States were included, Victor Emmanuel would rule over a population of 26,000,000. It is divided into sixty provinces and 193 'circondarii,' or administrative districts, subdivided into 1597 'mandamenti,' embracing about 8000 parishes. It contains on an average 220 inhabitants to the square mile—a higher figure than that of France and Germany, but lower than that of England, Belgium, and the Netherlands. The greatest average is obtained in Lombardy and Sicily. Italy now ranks as the fifth power in Europe, being superior in population to Spain and Prussia.

Military and Naval Services.—It is unfortunate for the new kingdom that its non-recognition by Austria, and the ardent desire of the Italians to complete its unification by the addition of Rome and Venetia, compels the maintenance of a military establishment which presses heavily on its already burdened resources. The army, even on a peace footing—as constituted in 1863—numbers 157 generals, 15,337 officers of all ranks, and 227,250 rank and file. The cavalry includes 36,728 horses. In time of war, this force could be raised to 400,000 men.

The military organization of Italy is founded upon the old Sardinian law of conscription. A certain portion of all the young men who have attained twenty-one is levied annually for the standing army, while the rest are entered in the reserve, which, though required to muster annually for forty days' practice, can only be called out permanently in case of a war. This system is being gradually put into operation throughout the kingdom.

The Italian navy, in 1865, consisted of 98 steamers, of 20,760 horse-power, and 2160 guns; and 17 sailing-vessels, carrying 279 guns: in all, 115 men-of-war, with 2439 guns. The list, to which several additions have since been made, enumerated,

	Horse-power.	Guns.
5 iron-clad frigates, of	800 ...	60
1 screw-steamer of the line, of	450 ...	70
18 screw steam frigates, of	5800 ...	575
14 paddle steam frigates, of	4300 ...	102
4 screw steam corvettes, of	888 ...	108
20 paddle steam corvettes, of	1,880 ...	65

Revenue, Expenditure, and National Debt.—The national debt of Italy, in 1864, amounted to 152,698,839*l.*, with a yearly interest of 7,896,689*l.* This heavy burthen has originated in various causes, which have been clearly set forth by a writer in the *Fortnightly Review*. 'By a rough application of force,' he says, 'half a dozen states were welded into one. That involved heavy expenses. The liberators took payment in money as well as in kind; and Italy lost provinces, and was saddled with a big debt. More than this; as she took over states, she took over also liabilities, and had to adopt not only the debts of kingly and ducal and imperial governments, but the civil services of half a dozen heretofore independent states. The war debts and the huge army of civil placemen are eating into the heart of her taxable resources. Nor is this all. Two dangerous issues, Rome and Venetia, remain unsettled, and necessitate the maintenance of a large army.' To restore order to the finances of Italy, and place them on a sound basis, is the task that will now try the mettle of her statesmen and the patience of her people.

The budgets of the kingdom of Italy for the two years 1864 and 1865 exhibited the following calculations:—

In 1864.	
Total estimated revenue,	£25,844,749
Total estimated expenditure,	35,214,417
Deficit,	9,369,668
In 1865.	
Total estimated revenue,	£25,020,101
Total estimated expenditure,	34,152,761
Deficit,	9,132,660

Now, let us look at the actual state of affairs. The revenue yielded in 1864 only 23,436,566*l.*, and the expenditure amounted to 38,519,788*l.*, leaving a deficiency of 15,083,222*l.* We may, therefore, reasonably calculate the deficits of 1864 and 1865 as amounting to an equal sum. And it is this difficulty—this annual excess of expenditure over income—which lies in the way of Italy's national progress. A more favourable prospect, it is true, now gladdens the hearts of Italian statesmen, and the minister of finance hopes to obtain a less unsatisfactory balance of revenue and expenditure for the year 1867. The expenditure he estimates at 928,000,000 lire (nearly 35,000,000*l.*), and the revenue at 848,000,000 lire (about 29,000,000*l.*); leaving a deficit of only 6,000,000*l.*

Manufactures, Trade and Commerce.—Italy is not generally a manufacturing country, but the production of silk goods is carried on to a large extent, and gives employment to a vast number of the population in most of the towns of Lombardy, and to a less degree in other parts of the country. In Piedmont this branch of industry has greatly progressed of late years, and the silk manufactures of Turin now almost rival those of Lyons. Coarse woollen goods are also made both in Lombardy and elsewhere, and supply the ordinary clothing of the peasantry. Milan is celebrated for its manufacture of weapons, and iron work of all kinds is extensively carried on there. The making of cotton fabrics, straw hats, paper, parchment, leather, glass, porcelain, and musical

instruments, is also pursued in various parts of the country; but the main wealth of Italy consists in its raw produce. The chief supply of manufactured articles, whether of luxury or necessity, is derived from abroad. Though the Italian kingdom is still in a transition state, and the full development of her resources is impeded by the causes already mentioned, her foreign trade assumes considerable dimensions. France appears to be her best customer, as might be supposed from the propinquity of the two nations, and Great Britain stands second in order. She herself imports from Great Britain large quantities of cotton stuffs, yarn, railway iron, guns, and ammunition. From Odessa and Alexandria she imports corn, wool from the Levant, and wines from France and Spain. Leghorn is the great commercial dépôt of Italy, and the seat of the most extensive foreign trade, but great activity prevails both at Genoa and Naples.

The exports consist of olive-oil, wines, silk, kid and lamb skins, borax, alum, sulphur, marble, straw hats and plaits, cheese, fruits, oak and cork bark, timber,

potash, charcoal, choral, anchovies, sardines, wax, essences, perfumery, liquorice, macaroni, porcelain, majolica, musical instruments, cloth of gold and silver, mosaics, and carvings in stone and wood.

The commercial intercourse of the new kingdom with the chief European states in 1863 is shown in the following table:—

	Imports.	Exports.
France, . . .	£7,033,984	£5,720,629
Great Britain, .	5,903,233	2,355,583
Austria, . . .	1,872,222	1,205,875
Switzerland, .	1,341,033	2,268,281
Netherlands, .	916,443	153,279
Russia, . . .	601,906	814,581
Belgium, . . .	561,280	84,360

The commercial intercourse of Italy with the United Kingdom is shown in the subjoined statement, which gives the value of the imports from the four territorial divisions of that country into the United Kingdom, and of the exports of British and Irish produce and manufactures to Italy in the five years 1860–64.

IMPORTS FROM ITALY INTO THE UNITED KINGDOM.

Years.	Two Sicilies.	Sardinia.	Tuscany.	Adriatic Ports of Ancona and the Romagna, and Papal Ports on the Mediterranean.	Total for the Kingdom of Italy.
1860	£1,867,904	£265,713	£575,064	£39,843	£2,748,524
1861	1,540,453	260,344	560,917	118,350	2,480,064
1862	1,865,239	263,198	441,088	48,786	2,618,311
1863	1,448,218	281,191	558,471	70,328	2,358,208
1864	1,522,466	227,512	388,712	42,410	2,181,097

EXPORTS OF HOME PRODUCE FROM THE UNITED KINGDOM TO ITALY.

1860	1,321,339	1,864,338	1,034,435	294,175	4,514,287
1861	2,071,521	2,198,948	1,062,881	447,719	5,781,069
1862	1,528,904	2,143,772	935,426	495,218	5,103,320
1863	2,309,273	2,114,380	1,073,669	430,658	5,927,980
1864	2,454,645	1,910,111	951,153	354,176	5,670,085

The chief articles of import from the Two Sicilies are olive oil and brimstone, the first amounting in 1864 to 430,915*l.*, and the second to 292,362*l.* From Sardinia and the Adriatic and Papal ports the imports are miscellaneous, olive oil amounting in 1864 to 43,578*l.*, marble to 10,448*l.*, and cream of tartar to 16,585*l.* The only articles of importance from Tuscany were olive oil 84,442*l.*, marble 62,515*l.*, and boracic acid 48,774*l.* Cotton goods form the staple export of the United Kingdom to Italy. In 1864 the Two Sicilies took 622,163*l.* worth, Sardinia 362,945*l.*, Tuscany 279,421*l.*, and the Adriatic ports 88,752*l.* The other principal articles were coal, copper, iron, linen and woollen manufactures. With the Papal States the intercourse is very slight, the total British exports thereto only amounting to 26,868*l.* in 1863, and 72,589*l.* in 1864.

In addition to the above, the exports to Italy of foreign and colonial produce and manufactures from the United Kingdom in 1864, were valued at 1,070,673*l.*, making the total amount 6,740,758*l.*

The total number of ships engaged in the foreign commerce of Italy during the year 1862 was 40,692; tonnage, 5,801,843; of which 20,188 entered, and

20,576 cleared out of, the ports of the kingdom. The coasting trade employed 173,695 vessels, tonnage 8,495,802; and the steamers arriving numbered 7441, tonnage 1,534,507. The coasting trade is almost wholly carried on in native bottoms; the proportion of foreign ships engaged in it not exceeding 16 in 1000, but of every 100 steamers, 19 are foreign.

The number of seamen employed amounted in 1862 to 948,819; of whom 259,669 were engaged in the foreign commerce, and 689,150 in the coasting trade. The foreign seamen numbered 201,080, and the native 747,739. The number of fishing-boats was 8835.

With the exception of Great Britain, therefore, Italy possesses the largest mercantile navy in Europe, and her seamen are distinguished for skill, activity, and courage. In the event of a European war, if she became the ally of France, she would reinforce her with a great accession of maritime strength.

The Italian steam mercantile navy, inclusive of the Austrian Lloyd's Company, numbers 125 vessels, with an aggregate of 47,092 tons. The extent of coast is large in comparison with the superficial area of Italy—viz., 3353 English miles.

Italian Government and Constitution.—Italy is a constitutional monarchy, and the legislative power is

exercised by the king and two houses of parliament—namely, the Senate (or Upper House), and the Chamber of Deputies (answering to our House of Commons). The Senate consists of the royal princes (when of age), and of other members, unlimited in number, who are nominated by the king for life, and must have attained the age of forty years. The members of the Chamber of Deputies are chosen by the qualified electors throughout the kingdom. A deputy must be thirty years of age, must have a slight property qualification, and cannot be declared elected unless at least one-third of the electors of the district have cast their votes at the election. For the purpose of choosing deputies, the whole kingdom is divided into districts, and every male who pays taxes to the amount of 30s. is a voter. The term of election is five years, and the Parliament sits for the same period, unless dissolved by the king. Sessions must be held annually. The Chamber of Deputies contains 443 members, or one to every 50,000 inhabitants.

The king is advised by a ministry, who are responsible to the Parliament. Each of the chambers has the right of introducing new bills, the same as the government; but all money bills must originate, as with us, in the Lower House. The ministers have the right to attend the debates of both the upper and lower houses, but cannot vote unless they are members. Both chambers hold their sittings in public, and no sitting is valid unless an absolute majority of the members be present.

Religion and Education.—The established religion of Italy is the Roman Catholic, but all creeds are now tolerated in the kingdom in conformity with the laws. Protestantism is making considerable progress, thanks to the efforts of many earnest and devout men. In 1864 no fewer than 30,000 bibles and testaments were sold in Italy, besides about 75,000 religious books and pamphlets of a Protestant character. The Roman Catholic hierarchy consists of 45 archbishops and 198 bishops. All those dignitaries are appointed by the pope, on the advice of a council of cardinals—the congregation 'De propagandâ fide.' But the royal sanction being necessary to the installation of a bishop or archbishop, and this having been frequently withheld of late years, there were recently no less than thirty-five vacant sees, about one-seventh of the whole number. On the death or removal of a prelate, the clergy of the diocese elect a vicar-capitular, who exercises spiritual jurisdiction during the vacancy. In case of old age or infirmity, the bishop nominates a coadjutor to discharge the episcopal duties in his stead. The recommendation is generally approved by the pope, and the bishop-coadjutor is appointed and consecrated, and takes his title from some imaginary oriental diocese, which he relinquishes on succeeding to an actual bishopric. As long as he retains the oriental title, he is styled a bishop 'in partibus infidelium,' or, as usually abbreviated, a bishop 'in partibus.'

The immense wealth of the Italian clergy has been greatly reduced since the year 1850, when Siccardi's bill for abolishing the immunities of the clergy and ecclesiastical jurisdiction passed the Sardinian chambers. This law was extended, in 1861, over the whole kingdom. It is intended, also, to introduce great reforms into the monasteries and convents still

existing, and which escaped the suppression-movement of 1861. The total number of Roman Catholic clergy in Italy may be computed at 500,000, and they necessarily exercise a very considerable influence, especially in the southern provinces. In the Waldensian valleys of Piedmont—the scene of Simon de Montfort's sanguinary crusades—about 20,000 native Protestants cherish the simple faith of their forefathers; and scattered over the country are about 50,000 Jews, chiefly engaged in commercial pursuits.

Education is at a low ebb in Italy. The mass of the adult population exhibit a deplorable amount of ignorance, and many even of the upper orders can neither read nor write. But since the establishment of the new government, great efforts have been made to remove this stigma from the national character. A great part of the property which belonged to the suppressed monastic institutions has been devoted to the furtherance of public education, and for the same noble object an annual credit of 600,000*l.* is set apart by the Parliament. Numerous normal and model schools, on British principles, have been organized; but although much has been done, more remains to do, for in the Neapolitan provinces alone 3000 large parishes have no school whatever.

The universities of Italy have declined from that palmy state of splendour and reputation which they occupied in mediæval days, when their enlightening influence extended into every civilized country. They are now fourteen in number:—Bologna, founded in 1119; Naples, 1244; Padua, 1228; Rome, 1244; Perugia, 1320; Pisa, 1329; Sienna, 1349; Pavia, 1390; Turin, 1412; Parma, 1422; Florence, 1443; Catania, 1445; Cagliari, 1764; Genoa, 1783.

To these may be added the high schools of Palermo, Camerino, and Maurata. The University of Modena was closed in 1849.

Italy contains a great number of public libraries, many of which are exceedingly opulent in ancient manuscripts and rare old books, though generally deficient in works of science and modern literature. Galleries of art and museums flourish in most of the principal towns, and those of Florence, Rome, and Naples enjoy a world-wide reputation. Every palace contains art-treasures of priceless worth, and the churches are enriched with masterpieces of painting and sculpture.

National Character and Present Condition of the Country.—'The Italian population,' says a trustworthy writer, 'is unquestionably far behind the British in the enjoyments of civilized life, in the useful arts, in civil and political liberty, in wealth, intelligence, industry, and in its moral condition. But the character of the nation exhibits the most surprising contrasts in different provinces. The Celt is not more widely opposed to the Saxon than the industrious and free-thinking Piedmontese to the careless, indolent, and ignorant Neapolitan, or the subtle and ingenious Florentine. Many years must elapse before these different elements can be welded into one homogeneous nation, but from the progress Italy has already made, her well-wishers cannot but augur favourably for her future. Her people are quick, vivid, and ardent; her natural resources are almost inexhaustible. Under a constitutional government what may not be expected from the wise development of the one, and the steady advancement, moral

and intellectual, of the other? Genoa, Venice, Florence, Rome—those great and illustrious cities may yet attain to a degree of prosperity which shall surpass all the glories of their historic past.'

History.—The annals of ancient Italy are comprised at the outset in those of Etruria, and afterwards in those of Rome. In our limited space it would be impossible to do justice to a subject so extensive; and the reader will do well to consult the numerous valuable authorities existing in the English and German languages—Niebuhr, Arnold, Merivale, Heeren, Mrs. Hamilton Gray.

The modern history of Italy begins with the downfall of the Western empire, whose last feeble ruler, Romulus Augustus, was dethroned by his Prætorian guards. Odoacer, their leader, assumed the title of King of Italy, and thus the country was separated from the Roman empire. The sovereignty founded by Odoacer lasted no longer than 493, when it was overthrown by Theodoric, king of the Ostrogoths. A period of confusion followed, which the reader may study in the elaborate pages of Gibbon, and which was only terminated by the establishment of the power of the Lombards in northern Italy. This brave and sagacious people soon spread their influence over the whole of the country, and menaced the independence even of Rome itself, whose popes, in their frequent alarms, generally solicited the assistance of the Frankish kings, and rewarded them with numerous privileges.

At the prayer of Pope Leo III., Charlemagne made war upon Desiderius, king of the Lombards, took him prisoner in his capital, and united his kingdom to his own vast empire. In return, the pope crowned him King of the Romans and Emperor of the West. Under the feeble rule of his successors the counts, marquises, and other great feudatories of the Western empire established their independence, and divided Italy into several distinct principalities. The Roman pontiffs gradually increased their influence and their possessions, and finally asserted their secular supremacy in the person of Innocent III., about 1200. The union of the temporal with the spiritual power enabled them to gain a complete ascendancy over the clergy and laity of all Europe, and in due time the Roman bishop was transformed into the infallible Head of the Church.

Still further to complicate the internal divisions of Italy the principal towns, as they grew in wealth and augmented in population, threw off the yoke of the feudatory princes, and declared themselves independent commonwealths. Thence arose a dark series of intestine tumults; of wars between the towns and the great lords; of the towns with each other; of the great lords among themselves; and, finally, of the towns and lords against the German sovereigns, who professed to be the successors of Charlemagne, and proclaimed themselves kings of Italy and emperors of the West. Out of this ferment and disorder eventually rose several powerful and prosperous states, the various stages of whose growth are recorded in the pages of Sismondi: such as the Papal hierarchy, the Norman kingdom of Sicily and Apulia, the republics of Venice, Florence, and Genoa, and, lastly, the duchy of Milan. In the north of Italy the house of Savoy acquired extensive possessions. Genoa and Venice thrived as great naval powers, the latter sur-

living until the outbreak of the French revolution; and Florence becoming the centre of art, literature, and commerce, dowered the world with the genius of Dante, Machiavelli, and Michael Angelo. It was afterwards merged in the Grand Duchy of Tuscany, and about the close of the seventeenth century Italy was divided into the seven leading states enumerated at the commencement of this article: Austrian Italy, Piedmont, Duchies of Parma, Modena, and Tuscany, the Papal States, and Kingdom of the Two Sicilies.

Such was the division existing when Napoleon entered upon his meteor-like career, and poured his troops into Italy in 1791. A succession of rapid movements and brilliant victories compelled the king of Sardinia to purchase the safety of his throne by the cession of Savoy and Nice. Austrian Lombardy was overrun and conquered, and the Roman pontiff and the duke of Parma only secured a temporary immunity from invasion by heavy sacrifices.

In 1797, Napoleon formed the Cisalpine republic out of Milan, Mantua, Modena, portions of Parma, Bologna, Ferrara, and Romagna—a republic which could only flourish under the shadow of French bayonets. In the following year Naples was constituted into a Parthenopean republic, and various other changes in the partition of unhappy Italy threw it a bound and helpless victim at the feet of revolutionary France. Thus it remained until Napoleon assumed the imperial purple, when he flung aside all pretence of respecting Italian liberty, and founded the kingdom of Italy, placing the iron crown on his own brow, and appointing his stepson, Eugene Beauharnois, viceroy. This did not include Naples, which was erected into a separate sovereignty for the dashing cavalry leader, *le beau sabreur*, Joachim Murat; nor Tuscany, which, as a grand duchy fell to the lot of Napoleon's sister Eliza. In 1809 the secular authority of the pope was declared at an end, and the States of the Church occupied by the French. Rome became the second city of the empire, and a pension of 2,000,000 francs was assigned to the 'Holy Father.'

With the fall of Napoleon, Italy returned in most respects to its normal condition, except that Austria was enriched and strengthened by considerable territorial accessions, notably those of Milan and Venice. The growth of liberal opinions and the rise of a national spirit, however, soon disturbed the seeming tranquillity of the peninsula, and in 1830, stimulated by the success of the French revolutionists, Modena, Bologna, Parma, and other states, broke out into revolt. As they derived no assistance from any European power, Austrian bayonets quickly restored the expelled princes, who were virtually lieutenants of the Austrian emperor. But the desire of independence, and the bright dream of Italian unity, had taken too firm hold of the minds of the Italians to be readily annihilated, and as this desire increased—as this dream developed—so grew a bitter hatred against the tyranny of Austria, which was fomented by the exhortations and encouragements of one who, if often mistaken, must nevertheless be considered the foremost and most persevering of Italian patriots, Giuseppe Mazzini.

At this crisis the king of Sardinia stepped forward to lead the new movement in the character of a constitutional monarch, and Pope Pius IX. having inaugurated his pontificate with various liberal measures, the prospects of Italian liberty seemed to

have suddenly brightened. The first outbreak took place in Lombardy in March, 1848, and resulted in the evacuation of Milan by the Austrian army. A provisional government was established, who straightway issued an energetic proclamation, summoning all Italians to arm for the holy cause of Italian independence. Charles Albert, king of Sardinia, immediately led his forces to the assistance of the insurgents, and at first was successful in every encounter. But the Austrians soon mustered in great strength, and the command-in-chief was conferred upon one of the ablest soldiers of his age, Marshal Radetzky, a veteran with whom Charles Albert was wholly unable to cope. Even then the united armies of the Italian states might have prevailed against the enemy, had not the Pope, alarmed at the progress of the revolutionary spirit which he had helped to evoke, suddenly deserted the national cause. The Neapolitan soldiers were immediately recalled, but for a while the revolution still made head. Rome declared itself a republic, and proclaimed Mazzini its Dictator, compelling the pope to seek refuge in an undignified flight. But the Austrian arms soon turned the tide of battle, and at Novara the Piedmontese were totally defeated (March, 1849), despite of the most energetic valour. Charles Albert, on the evening after the fight, abdicated in favour of his son, Victor Emmanuel, and withdrew, with broken heart and blighted hopes, to die in a few brief months at Oporto.

Rome still held out; but the French republic, in defiance of its own principles, and out of an insatiable greed of conquest, marched an army into Central Italy, and compelled the Eternal City to surrender, after enduring all the horrors of pestilence and famine. This event was followed by the restoration of the pope, who returned to Rome on April 12, 1850, and has since reigned over a discontented people, through the assistance of French bayonets.

The revolution was over, and it seemed as if that vision of an united Italy, which had once animated the song of Petrarch and the eloquence of Rienzi, could never again be revived. But a new character now appeared on the scene, Count Camillo Cavour, a statesman of the highest intellect and most resolute purpose, who, called to the administration of affairs in Piedmont, took advantage of his position to keep alive the hopes of his countrymen, and to build up, stone by stone, the stately structure of their independence. Happy the nation which, in the crisis and agony of its fate, can turn to no noble a spirit and determined a genius for the guidance it stands in need of! By developing in Piedmont a constitutional government he rallied the more enlightened and moderate Italians of all classes and parties round Victor Emmanuel, and accustomed them to look to him as their future leader. When the Russian war broke out, he despatched a contingent to serve with the allied armies in the Crimea, by which means he gave Piedmont a place among the European powers. Meanwhile, the other Italian states were wretchedly misgoverned, and the rich gifts of nature neglected by incompetent rulers. A spirit of discontent pervaded all Italy, which was finally fanned into indignant wrath by the atrocious cruelties practised in the dungeons of Naples, and exposed by the eloquent pen of Mr. Gladstone. At length, in 1859, the French emperor, partly from personal motives, and partly

from a desire to conciliate the 'nationalities' of Europe, suddenly stepped into the arena as the champion of Italy, and in the great battles of Magenta and Solferino so humbled the Austrians that they were compelled to sue for peace. A treaty was signed at Villafranca, by which Austria agreed to surrender Lombardy, and consented to the formation of an Italian confederacy under the protection of the pope. The different states, however, would listen to no such compromise, and Parma, Modena, the Æmilian provinces, and Tuscany threw off the yoke of their respective rulers, and voluntarily annexed themselves to Piedmont. Nor could France openly break up this unexpected arrangement, as Great Britain supported it with all her influence, and vehemently urged the new political doctrine of 'non-interference.'

The southern provinces, though in a state of chronic disorder, still remained under the rule of Francis II., when Garibaldi, already distinguished by his patriotism, courage, and popularity, suddenly invaded Sicily with a small band of intrepid red-shirted followers (May, 1860), roused its inhabitants against the Neapolitan yoke, and drove the royal troops from point to point, until the entire island accepted Victor Emmanuel as king. He then crossed over to the mainland, and with wondrous daring entered Naples, which immediately declared in favour of union with Piedmont, and compelled its sovereign to retreat in hot haste to Gaeta, and from thence to Rome. The Sardinian army meanwhile had entered the Papal territories, and gained several victories, which resulted in the incorporation of Ancona and Umbria with the Piedmontese territories. Soon afterwards Victor Emmanuel formally declared himself King of Italy, and Cavour addressed himself to the task of consolidating the new kingdom.

In 1861, Garibaldi, in his eager desire to establish the seat of Italian government in that glorious city which for so many centuries was the actual 'mistress of the world,' raised a small body of volunteers, and invaded the Papal states. In hazarding this bold enterprise he probably believed that he had the secret approval of his sovereign, but Cavour recognized the danger to be apprehended of a collision between the Garibaldini and the French army—a collision which would have shaken the unstable foundations of Italian unity to the ground—and despatched a body of the royal troops to oppose his progress. At Aspromonte his small force was compelled to surrender. He himself was wounded in the ankle, but he refused to allow his followers to fire on the royal soldiers, as from the outset he had expressed his devotion to and his confidence in Victor Emmanuel.

Both Cavour and the king regretted this untoward event, and a general amnesty was immediately proclaimed.

Since that date affairs in Italy have remained *in statu quo*, except that by the death of Cavour in the early part of 1861 she has lost her most sagacious and moderate statesman—a master-mind not easily replaced; and that in pursuance of a convention between France and Italy, the Italian capital has been removed from Turin to Florence. The emperor has agreed to withdraw the French army of occupation from Rome in September of the present year (1866), while Victor Emmanuel has undertaken not

to attack the present territory of the pope, and to prevent by force any attack upon the said territory proceeding from the exterior—conditions which it is doubtful if his subjects will allow him to fulfil.

So—with arms in her hands; with heart still elate and hopeful; and with eager eyes fixed wistfully on Rome and Venetia, as necessary to the full development of her resources and the completion of her internal organization—Italy waits!

For information on Italian history, the reader should consult Botta, 'Storia d'Italia'; Muratori, 'Annales d'Italia'; Machiavelli, 'Istorie Fiorentine'; Gibbon, 'Decline and Fall of the Roman Empire'; Sismondi, 'Rise of the Italian Republics'; Hazlitt, 'History of Venetian Republic'; Trollope, 'Florentine History'; Ranke, 'History of the Popes'; Hallam, 'History of the Middle Ages'; Denina, 'Rivoluzioni d'Italia'; Daru, 'History of Venice'; Roscoe, 'Lives of Leo X. and Lorenzo de Medici'; Ellesmere, 'War of the Sicilian Vespers'; Dyer, 'History of Modern Europe'; Dicey, 'Count Cavour'; &c.

Italian Language, Literature, and Art.—The language called Italian is the written language of Italy, and exhibits the same analogy to the spoken language of Rome and Tuscany as the written language of England to the dialects spoken in its various counties. Several Italian dialects, however, exist, of which we may enumerate the principal:—1. The Milanese, spoken at Milan and in its vicinity, and cultivated by Maggi, Parini, Grossi, Porta, and other writers; 2. The graceful Venetian, exemplified in the works of Lamberti, Goldoni, and Buratti; 3. The Mantuan, illustrated by the eccentric writings of the monk Folengo; 4. The Piedmontese, in which Calvo has written; 5. The Genoese, whose peculiarities may be seen in Cavallis and Foghetta; 6. The rough and uncouth Bolognese; and 7. The Neapolitan, remarkable for its humorous character, and its adaptation to the purposes of imitative harmony. The latter has been cultivated by numerous writers.

It has justly been observed that we must not consider these dialects as corruptions of the written Italian, but as independent languages which were anterior to it, and arose from an amalgamation of the Latin with the relics of the tongues spoken by the various tribes that at different times invaded and colonized the peninsula. Owing to various causes, the Tuscan dialect first attained polish, *verve*, and completeness, and gradually became the language in which the sages and poets of Italy thought and sung. The great writers of the fourteenth century—Pandolfini, Sacchetti, Villani, Petrarca, Boccaccio, and the immortal poet of the 'Divina Commedia,' Dante—were all Tuscans, and their genius has impressed on the Italian language the stamp of the true Tuscan metal.

The writers of the fourteenth century—or first period of Italian literature—are called by the Tuscans the *Trecentisti*, and are considered by many as the finest models of Italian composition. Among them were Petrarca, Boccaccio, Dante—three names in themselves sufficient to give permanency and renown to a national literature.

The *second period*, from 1400 to 1500, embraces the age of Lorenzo de Medici, who was the friend of

poets, and himself a poet of no mean pretension. It was illustrated by the splendid intellects of Poliziano, author of the 'Orfeo,' the earliest classic Italian drama; Luigi Pulci, author of the 'Morgante Maggiore'; and Boiardo, the author of the 'Orlando Innamorato.' Many of the learned men and women of this age, however, elected to trammel themselves by writing in Latin: such as Alberti, Bracciolini, Bruni, Filelfo, Panormita, Platina, Pontana, Valla, Ficino, and Sannazaro.

From 1500 to 1600 is the *third period* of Italian literature, and a golden age of poetry, second only to the era of Dante. It is true, as Longfellow remarks, there appeared in it no one production that can bear a moment's comparison with

The poem sacred,

To which both heaven and earth have set their hands;' but it produced more great poems than any other period, such as the 'Orlando Furioso' of Ariosto, and the 'Gierusalemme Liberata' of Tasso. It was also distinguished by the labours of Michael Angelo in sculpture, Machiavelli in history, and Vittoria Colonna in letters generally.

From 1600 to the present time forms the *fourth period*. To the brilliant era of the Cinquecentisti succeeded the affectations and frivolities of the Sexcentisti, which ushered in the present age. The Italian mind, it has been said, contented or weary with the triumphs of the previous century, now found its chief expression in odes and sonnets, marked by conceits and exaggerated prettinesses of style.

The greatest poetic names of this period are Marini, Chiabrera, Redi, Filicaja, Maffei, Goldoni, Gozzi, Metastasio, Alfieri, Monti, Pindimonte, Ugo Foscolo, Manzoni, Parini, Mesillini, Silvio Pellico, Grossi, and Berchet. Mightiest among these stands Alfieri, a grand example of the power of a strong will and a fixed purpose. 'He is the last great sign in that celestial zodiac of Italian song, which encircles the earth with its glory, and of which Dante, in the majestic procession of the ages, was the first to appear above the horizon, chasing the darkness before him, and, like Sagittarius, filling the whole heaven with his golden arrows.'

Many of these names are associated with various branches of literary labour; and others, not enumerated above, are crowned with enduring fame. Thus, in criticism, we must not forget Zeno, Baretti, Gozzi, Mazzuchelli, and Cesarotti; the fine arts occupied the acumen and industry of Lanzi, Vasari, Bottari, and Milizia; Martini and Tartini are connected with the history of music; Verri, Neri, Carli, and Galiani wrote on political economy; Tiraboschi, Bettinelli, and Corniani, on Italian literature; Buonafede, on the progress of philosophy; Beccaria, Filangieri, and Mario Pagano, on jurisprudence; Vallisnieri and Spallanzani contributed important discoveries to our knowledge of the laws of nature and the conditions of animal life; Volta and Galvani are associated with the wonders of electricity and galvanism; Denina illustrated Italian annals; and Alfieri created the Italian tragedy.

Among the principal writers of the present century we may record—the historians Botta, Balbi, Arnari, Scopoli; the tragedians Miolini and Pellico—the latter the author of the well-known 'Picciola'; the romantic poets Grossi and Sestini; the didactic poet

Arici; the satirist D'Elci; the dramatist Grisi, and novelist Manzoni, author of the 'Promessi Sposi'; the novelist Rossini; and the dramatist Nota. Micali has written the annals of Italy prior to the palmy days of Roman glory; Bossi, a general history of Italy; Vacani, the services of the Italian troops employed in Napoleon's wars; Colletta and Cuoco, the story of Naples; Pignotti, the history of Tuscany; Manno, that of Sardinia; and Serra, that of Genoa. Cicognara has carefully compiled a history of sculpture; Ugoni and Lucchesini have criticized the Italian literature of the eighteenth century; Gioja has employed himself on political economy and legislation; Romagnosi and Tamburini have written on jurisprudence; Brocchi and Breislak, on geology and mineralogy.

What shall we say of Italian art? We can but refer to its great schools of painting—the Florentine, the Venetian, the Roman, and the Bolognese; to its triumphs in sculpture and music; and to the names of Raffaele, Michael Angelo, Perugino, Cimabue, Guido, Salvator Rosa, the Caracci, Giotto, Titian, Canova, Rossini, Bellini, Donizetti, among a thousand others which 'the world will not willingly let die.'

ITALIAN ARCHITECTURE. [CIVIL ARCHITECTURE.] Instead of comprising buildings of every style and class to be met with in Italy, the term Italian Architecture is generally restricted to signify that generic style formed by the revival of the Roman orders, and the adaptation of them, and other features derived from works of the same age, to buildings of every kind, domestic as well as public.

Different orders, or repetitions of the same order, being applied to the several stories of buildings whose fronts were pierced with windows, it became unavoidably necessary to abandon all proportion of intercolumniation, and to space the columns according to the breadth of the piers and the apertures between them; which in turn left hardly any other alternative than to engage the columns themselves, that is, to attach either half or three-quarter columns to the walls.

One defect attending this practice of giving a separate order to each story is, that the columns become insignificant, both in proportion to the entire front and to the windows between them, more especially when the columns are further shortened by being placed on pedestals. In fact, windows and doors are generally the predominant features in Italian composition, even where two series are comprised within one order, being generally more prominent in their cornices and pediments than the other projections. They are often decorated with smaller columns or pilasters, and Palladio has sometimes loaded them by recumbent figures on the raking cornices of their pediments. Probably the Italian style exhibits itself to most advantage where columns have been discarded, and windows and arches made the chief features in the composition, and the façade crowned by a bold and rich *cornicione*.

The Italian style was for a long time predominant in England, and many of our finest public buildings are good examples of it; but of late years a reaction has fortunately set in, under the auspices of the late Sir C. Barry, G. G. Scott, Ferrey, and others, in favour of the Gothic, which, when properly treated, is better adapted to our climate, and, it may be added, seems more in harmony with the national genius.

ITALIAN DRAMA. After the long sleep of the true dramatic and theatrical spirit in the middle ages, the first endeavour to imitate the ancients in their theatre, as in other departments of art and poetry, was made by the Italians. The earliest represented drama in a modern language was probably the 'Orfeo' of Poliziano, acted at Mantua in 1483; and next in point of date was a translation of the 'Amphitryo' of Plautus, produced at Ferrara in 1486.

It is needless to trace a long series of now unknown names of persons who wrote plays, or translated them from the ancient classic authors. It will be sufficient to state that the Italians never had a national drama in the higher sense of the word. The comedies of Porta possess some merit, and the plays of Alfieri are admirable and powerful works, but they have no pretence to nationality, though written with the desire to promote freedom among his countrymen. The Italians, however, were fond of theatrical representations, and Boiardo, Ariosto, Bibiena, Aretino, and Ludovico Dolce all wrote comedies in imitation of the antique.

Among the successful comic poets of this period, the most distinguished was Giambattista de la Porta, who flourished at the close of the sixteenth century and the beginning of the seventeenth. Though most of his comedies were of the familiar species, and some of them even bordered on farce, yet a few rose to the noble and pathetic tone: of the latter kind are 'La Furiosa,' 'La Cintia,' 'Le Due Fratelli Rivali,' 'La Sorella,' and 'Il Moro.' But the Spanish theatre was now approaching the meridian of its glory; and the political influence of Spain on the Italian territory being at its height greatly favoured the introduction of the Spanish taste in dramatic composition. It was probably the first extravagances of this dramatic innovation that induced Tasso, in his latter days, to compose, as a burlesque of the new romantic taste, a play entitled 'Love Intrigues' (GI' Intrichi d'Amore), which was acted in 1598 and printed in 1604. We find a curious evidence of the transitional state of the public taste at this time in the productions of a poet of high name who thought fit to try his powers in each of the rival species. This was Michael Angelo Buonarroti the Younger, nephew of the great Michael Angelo, who composed two comedies entitled 'La Tancia' and 'La Fiera.' 'La Tancia' is a rustic comedy, in which nearly all the characters speak the country dialect of Tuscany. 'La Fiera' (the Fair) is a connected series of five plays in five acts each, which were performed at Florence on five successive nights. A vast variety of characters are introduced for the purpose of exhibiting instances of the technical terms used in the various trades of Tuscany. [BUONAROTTI.]

Ottavio Rinuccini introduced the *opera per musica*, which we now briefly term the opera. The magic power of this union of music with the romantic drama made it the chief theatrical favourite among the Italians of the seventeenth century. At the same time the public continued their favour to a species of comedy, or rather comic recitation, which in Italy seems to have been in all times peculiarly national. This was called the *commedia a soggetto* or *commedia dell'arte*. It consisted of the mere outline of a dramatic composition, wherein the parts very slightly sketched were assigned to the several

performers, who were to fill them up extemporarily. These sketches were called *scenarij*, from their containing merely the argument of each scene: those of Flaminio Scala were particularly celebrated.

The task of classicizing the musical drama was undertaken first by Apostolo Zeno, and afterwards, with more success, by the Abbate Metastasio. The first endeavour to restore what the classicists denominated the *true comedy* was made by Luigi Riccoboni, a theatrical manager, who made an unsuccessful attempt, on the Venetian stage, to revive the 'Scolastica' of Ariosto. Better fortune awaited Carlo Goldoni, a Neapolitan, who displayed such abundant nature and fertility in painting the manners and the follies of his own age and country, that at length he brought the comedy of *character* into vogue. He was for a time driven out of the field by the fantastic dramas of Gozzi (which were fairy tales adapted to the stage, and sometimes Spanish plays remodelled), but was speedily reinstated in Italian favour, and from his pen we have about a hundred and fifty pieces. Among the comic dramatists of his own country he still occupies the highest place.

In the latter part of the last century, Alfieri inaugurated a new era of Italian tragedy. He adhered to the established classic school, took his subjects chiefly from ancient story, and was a strict observer of the unities. As a dramatist, he has been the most successful in painting, as in his 'Virginia,' the public life of the Roman republic; and in his tragedy of 'Saul' we find, with a certain oriental splendour, great lyrical sublimity of expression. Since Alfieri, that nobler and more masculine-spirited Italian tragedy, of which he is regarded as the founder, has been cultivated by several distinguished writers with a less rigid adherence to antique subjects and to classic forms. Among the most estimable of these productions we may particularize the 'Aristodemo,' the 'Cajo Gracco,' and the 'Galeotto Manfredi,' of Vicenzo Monti; 'Il Conte di Carmagnola,' and 'L'Adelchi,' of Alessandro Manzoni; and the 'Antonio Foscarini,' the 'Giovanni da Procida,' the 'Ludovico Il Moro,' and the 'Nabucco' of Giovan Battista Niccolini. For some years, however, Italy has produced no great dramatist, and her theatrical genius has mainly been devoted to operatic compositions. Nor can we regret the absence of new Alfieris and Goldonis while she supplies us with a Rossini, a Bellini, a Donizetti, and we may even add, a Verdi. For the early history of the Italian drama, consult Hallam's 'Introduction to the Literature of the Middle Ages.' No comprehensive work exists on modern Italian dramatic literature, but some interesting papers have appeared at intervals in the *Foreign Quarterly Review* and *Blackwood's Magazine*.

ITIHASAS, a name given to the two great Hindu poems, the 'Ramayana' and 'Maha Bharata,' which boast a venerable antiquity.

ITIS, a termination which, added to the root of the Greek name of an organ or part of the body, implies its inflammation; as *bronchitis*, inflammation of the bronchia.

IULUS, a genus established by Linnæus for such *Insecta Myriapoda* as now form the order *Chilognatha* (χιλός, γνάθος) the first division of *Myriapoda* in the arrangements of Leach and Latreille. The

Chilognatha have crustaceous and usually cylindrical bodies, formed of numerous unequal segments, very short feet, each terminating in a single hook; a vertical rounded head, furnished with two mandibles, which are either thick and robust, or united with the labium and elongated. They have no palpi. The antennæ are two, very short, either slightly thickened towards their extremities, or filiform throughout, and composed usually of seven, more rarely (as in the genus *Sphæropæus*) of six joints. Their eyes are smooth, and vary greatly in number. These animals move slowly and with a gliding motion. When disturbed, they roll themselves up spirally, or into a ball. They feed on decomposing animal and vegetable matter.

The chilognathous Myriapoda are found in all parts of the world, certain genera, however, affecting certain geographical divisions. Thus the species of *Glomeris* are European; those of *Spirastrepus* and *Sphæropæus*, African and Eastern. *Iulus terrestris* is a familiar British example.

IVES, ST. [CORNWALL; HUNTINGDONSHIRE.]

IVINGHOE. [BUCKINGHAMSHIRE.]

IVIZA. [BALEARIC ISLANDS.]

IVORY (Lat. *ebur*), the name given to the substance of the tusks of elephants, and of the walrus or sea-horse, is extensively used for the handles of knives and forks, and for making or embellishing numberless small articles in general use. Each male elephant, when arrived at maturity, has two tusks; these are hollow at the root, tapering, and of various sizes, depending chiefly on the age of the animal. The best sort comes from Africa, and is of a closer texture and of a better colour than that brought from the East Indies. The medium weight of a tusk may be taken at 60 lbs. The Chinese are very ingenious in working, and especially in carving, ivory; their concentric balls, ivory boxes, and chessmen are far superior to those constructed by any other race of people. The Chinese market is principally supplied with ivory from Malacca, Siam, and Sumatra. For making artificial teeth the ivory of the walrus is preferred. The principal supplies of elephants' tusks to this country are from the west coast of Africa and from Ceylon. The remaining imports are from Bombay, the Cape of Good Hope, Madagascar, and Siam. The quantity imported in 1864 was 11,497 cwts., valued at 361,384*l*.

IVORY BLACK. [CHARCOAL, ANIMAL.]

IVORY COAST. [GUINEA.]

IVORY PALM, one of the finest productions of the vegetable kingdom (the *Phytelephas macrocarpa* of botanists), sometimes called *Vegetable Ivory*. It is an inhabitant of the Magdalena, in New Grenada; and the seeds constitute a substance so much like ivory, that they have become an important article of commerce.

IVRY. [EURE.]

IVY (Anglo-Saxon, *ifig*). [HEDERA.]

IXORA, a genus of rubiaceous plants of the tribe *Chinchonaceæ*. The species are numerous, and chiefly confined to India and the Oriental Archipelago. They form shrubs or small trees. The flowers are in terminal corymbs, and are usually red, but sometimes white, and are generally highly ornamental, whence several are cultivated in our hot-houses, where they require to be kept in a moist heat.

J.

J in the English language has a sibilant sound, closely connected with that of the syllable *di* before a vowel. It has a similar, though not the same, sound in the French tongue; but in German it is pronounced like our *y* before a vowel. Though it is generally said that its power with the Romans was the same as with the Germans, there is reason for thinking that our own sound of the letter was not unknown to the ancient inhabitants of Italy. The name of Jupiter was undoubtedly written originally *Diupiter*, so Janus was at first *Dianus*, just as the goddess Diana was called by the rustics *Jana*. [D and I.] The argument might be strengthened by comparing the Latin *jungo* with the Greek *ζωγνυμι*, Jupiter with *Ζευ πατρις*, &c., and also by referring to the modern Italian forms, *giogo*, *giovare*, *giovenco*, &c. Two pronunciations may have co-existed in the same country. As to the form of the letter *j*, it was originally identical with that of *i*, and the distinction between them is of recent date.

In the Spanish language *j* represents a guttural, and is now used instead of *x*, which had the same power: thus *Jeres* rather than *Xeres* is the name of the town which gives its title to the wine called by us sherry. For the changes which *j* may undergo see D, G, and I.

JA'BIRU, the name of a genus of Grallatorial or Wading Birds, *Mycteria* of Linnæus, and thus characterized:—Bill long, conical, smooth, robust, compressed, and pointed; upper mandible trigonal and straight, the lower thicker and turned up. Head and neck more or less bare of feathers. Anterior toes united at the base by a membrane. Size gigantic. Is found in South America, Western Africa, and Australasia. Habits almost entirely the same as those of the Storks. There are three species known, distributed geographically as above.

JACANA (*Parra jacana*), a species of bird belonging to the order *Grallæ*, and to the family *Palamedidæ* (Gray), or Waders. The members of the genus *Parra* are noted for their short bills, thickened and advanced at the base, and their long and slender toes. They are found in the tropical regions both of the Old and New World, frequenting the marshes and rivers. Their food is chiefly vegetable. The common Jacana is a native of Brazil and the West Indies. It frequents the Amazon and other rivers, where it may often be seen walking on the enormous leaves of the Victoria regia, and other water-plants.

JACAR. [CASTILLA-LA-NUEVA.]

JACCHUS, or **IACCHUS**, the name of a genus of monkeys applied by Geoffroy, Desmarest, and others to the form denominated *Hapale* by Illiger, *Ouistitis* of the French, the type of which may be considered to be *Simia Jacchus* of Linnæus.

Upper intermediate incisors larger than the lateral ones, which are isolated on each side; lower

JACKAL.

incisors elongated, narrow, and vertical, the lateral ones longest; upper canine teeth conical and of moderate size; two lower ones very small.

Incisors, $\frac{4}{4}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{6-6}{6-6} = 36$.

Size small, muzzle short, facial angle about 50°. Head round, prominent at the occiput; the five fingers armed with claws, with the exception of the thumbs of the posterior extremities, which are furnished with nails; thumb of the anterior extremities in the same direction as the fingers; fur very soft; tail full and handsome. A native of South America.

The species are all of diminutive size, rather numerous, and are generally known by the name of *Marmosets*. Habits squirrel-like. The food consists of fruits, roots, seeds, insects, eggs, small birds, and nestlings.

JACK, in the British navy is a small union flag composed of a field of blue, bearing a St. George's cross over a St. Andrew's cross, both of which are red and have a margin of white.

JACK. The Jewish *Jacobus* was corrupted through Jacquemes to *Jacques* in France, and *James* in England; and Jacques being the commonest Christian name in the former country, was used as a contemptuous expression for a common man. (*Jacquerie*, an insurrection of the peasantry.) The introduction of the word in the same sense into England seems to have led to the use of Jack as the familiar synonym of John, which happened to be here the commonest name, as Jacques in France. The term was then applied to any mechanical contrivance for replacing the personal service of an attendant, or to an implement subjected to familiar usage—as boot-jack, jack-boots, jacket.

JACKAL, or **TSCHAKKAL**, the name of a section of *Carnivora*, placed by most naturalists within the pale of the genus *Canis*, and of which the Common Jackal is an example. This animal is the *Chacal* or *Loup doré* of the French; *Adivé* of Buffon; *Canis aureus*, Linnæus.

Description.—Yellowish gray above, whitish below; thighs and legs yellow; ears ruddy; muzzle very pointed; tail reaching hardly to the heel (properly so called). The colours sometimes vary, and the back and sides are described as of mixed gray and black, and as abruptly and strikingly distinguished from the deep and uniform tawny of the shoulders, haunches, and legs. The head nearly of the same mixed shade with the upper surface of the body. Odour offensive.

Geographical Distribution.—India, other parts of Asia, and Africa. Cuvier says that Jackals are met with from India and the environs of the Caspian Sea to Guinea, but that it is not certain that they are all of the same species.

Habits nocturnal and gregarious, hunting in packs, and the nests of the countries where they are found, and where they burrow in the earth. In their huntings the Jackals will frequently attack the larger quadrupeds, but the smaller animals and poultry are their most frequent prey. Their cry is very peculiar and piercing. Captain Beechey notices it as having something rather appalling when heard for the first time at night; and he remarks that, as they usually come in packs, the first shriek which is uttered is always the signal for a general chorus. 'We hardly know,' continues the captain, 'a sound which partakes less of harmony than that which is at present in question; and indeed the sudden burst of the answering long-protracted scream, succeeding immediately to the opening note, is scarcely less

Jackal (*Canis aureus*).

impressive than the roll of the thunder-clap immediately after a flash of lightning. The effect of this music is very much increased when the first note is heard in the distance (a circumstance which often occurs), and the answering yell bursts out from several points at once, within a few yards or feet of the place where the auditors are sleeping. These animals are said to devour the dead on the battlefield, and to scratch away the earth from the shallow graves in order to feed on the corpses.

The story of the Jackal being the lion's provider may have arisen from the notion that the yell of the pack gives notice to the lion that prey is on foot, or from the Jackal being seen to feed on the remnants of the lion's quarry.

JACKASS, LAUGHING. [KINGFISHER.]

JACKDAW. [CORVIDÆ.]

JACKSON, ANDREW, President of the United States of North America, was descended from a Scottish family which had settled in Ireland, whence his father, Andrew Jackson, with a wife and two sons, emigrated in 1765 to South Carolina, where his third and youngest son, Andrew, was born, March 15, 1767. The father died soon afterwards.

Andrew appears to have been his mother's favourite; and his original destination was to be a clergyman. With this view, he studied theology for some years; but when the War of Independence commenced the young Jacksons did not hold back. Andrew is recorded to have fought when little more than thirteen. And from this time he shared in every campaign as long as the war lasted. In 1784 he placed himself under an advocate to be instructed

in the law. This new study he prosecuted with so much success, that in 1787 he was appointed solicitor for what was then called the Western District of North Carolina, and is now the state of Tennessee; but he did not entirely throw off his military character, and he served with distinction, though only as a private, against the Indians, who had become troublesome to the state.

Having acted as one of the members of the convention for establishing a constitution for the state of Tennessee, he was, in 1796, elected to a seat in the House of Representatives. The next year he was chosen a senator, but resigned his seat after holding it for one session, and was nominated by the legislature of Tennessee a judge of the Supreme Court in that state, having also been shortly before appointed a major-general of the state forces. But he resigned his judicial office, and lived in retirement on a farm, a few miles from Nashville, on the Cumberland river, till the breaking out of the war with England in 1812.

His first command was that of a body of between two and three thousand volunteers, with whom he proceeded down the Mississippi for the defence of the lower country in November, 1812. The next year he greatly distinguished himself by a campaign against the Creek tribes.

In 1814 Jackson was appointed a major-general in the service of the United States. He captured Pensacola on November 7, and raised himself to the highest point of reputation and popularity among his countrymen by the famous repulse of the British forces in their attack on New Orleans, January 8, 1815. The next military command which he held was in the war against the Seminole Indians of Florida in 1818.

General Jackson was commissioner on the part of the United States in the negotiation with Spain for the transference of Florida; and after the arrangement he was, in 1821, appointed the first governor of the province. He held this post for a year, and was then again elected a member of the senate for the state of Tennessee.

When the election of a new president took place at the end of 1824, General Jackson was a candidate along with Mr. Adams, Mr. Clay, and Mr. Crawford. Mr. Adams became president on this occasion, but General Jackson was elected in 1828, and again in 1832; so that he was at the head of the government of his native country for the eight years from 1829 to 1837.

General Jackson survived his presidency about eight years, and died at his seat called the Hermitage, near Nashville, in Tennessee, June 8, 1845. He was married, but had no issue.

JACKSON, JOHN, R.A., was born in 1778, at Lavingham, in Yorkshire, and was apprenticed to a tailor; but Lord Mulgrave and Sir George Beaumont having seen his imitation of a picture by Reynolds, and some other proofs of his talent, they encouraged him, purchased the unexpired term of his apprenticeship, and sent him to London in 1794 to study in the Royal Academy.

He first attracted notice as a portrait painter in oil about 1806, and in 1817, when he was elected a member of the Royal Academy, his reputation was little inferior to that of Lawrence. In the summer

of 1819 he visited Rome in company with Chantrey, and there painted for him a portrait of Canova. His best works are the portraits of Lady Dover, of Flaxman, and of himself, both painted for Lord Dover, and the portrait already mentioned. Jackson died June 1, 1831.

JACKSON, PORT. [SYDNEY.]

JACKSON, WILLIAM, was born in 1730, at Exeter, of which place his father was a respectable tradesman. He was placed under the tuition of the organist of the cathedral, and completed his studies in London, under the celebrated Travers, of the Chapel-Royal. He returned to and settled in his native city, and in 1777 was appointed sub-chanter, organist, lay-vicar, and master of the choristers of the cathedral. He died in 1803.

Jackson first made himself known as a composer by the publication of 'Twelve Songs,' which immediately spread his fame throughout the kingdom. His reputation was maintained by many other works. His 'Twelve Canzonets for Two Voices' were once the delight of every musical circle. Of these, 'Time has not thinned my flowing hair,' and 'Love in thine eyes for ever plays,' have lost none of their charms. Of three dramatic compositions, 'The Lord of the Manor' alone survives.

JACOBI, FRIEDRICH HEINRICH, was born at Düsseldorf, in 1743, and died at Munich, 10th March, 1819. He was distinguished, not so much as the author of a peculiar system of philosophy, as for the critical acumen and forcible eloquence with which he detected and exposed the incoherences and defects of the prevailing systems. His earliest publication was a philosophical poem, entitled 'Friendship and Love,' which first appeared in 1777, afterwards republished under the title of 'Woldemar.' In 1781 he commenced an able controversy with Mendelssohn, in his work 'On the doctrine of Spinoza,' which he further prosecuted in his 'Observations on Mendelssohn's Apology for the doctrine of Spinoza.' By the essay, entitled 'David Hume, or Idealism and Realism,' he provoked the hostility of the followers of Kant, and that of the admirers of Fichte by his 'Sendschreiben an Fichte.' When the troubles arising out of the French Revolution extended to Germany, Jacobi retired to Holstein, whence he removed successively to Wandsbeck and Hamburg; from the latter he was called, in 1804, to Munich, to assist in the formation of the new Academy of Sciences, of which he was appointed president in 1807. This dignity Jacobi resigned in 1813, upon attaining his seventieth year. Shortly before, his work 'On Divine Things and on Revelation' (Leipzig, 1811), had involved him in a bitter controversy with Schelling. Jacobi's complete works have been published in 6 vols., Leipzig, 1812-24.

JACOBINS is the name of a faction which exercised a great influence on the events of the French Revolution. This faction originated in a political club formed at Versailles, about the time of the meeting of the first National Assembly, and which was composed chiefly of deputies from Brittany, who were most determined against the court and the old monarchy, and some also from the south of France, among whom was Mirabeau. When the National Assembly removed its sittings to Paris (October 19, 1789), the Breton club followed it, and

soon after established their meetings in the lately suppressed convent of the Jacobins, or Dominican monks, in the Rue St. Honoré. From this circumstance the club and the powerful party which grew from it assumed the name of Jacobins. During the year 1790 the club increased its numbers, and obtained such influence and power, especially in 1792, as to control the legislature. The attack on the Tuileries in August, 1792, the massacres of the following September, the suppression of royalty, and most of the measures of the reign of terror, originated with the club of the Jacobins. After the fall of Robespierre in July, 1794, the convention passed a resolution which forbade all popular assemblies to interfere with the deliberations of the legislature, and the club was finally suppressed in 1794. The more violent Jacobins were called *Cordeliers*; the more moderate, *Feuillants*.

JACOBITES. [EUTYCHIANS; STUART FAMILY.]

JACOB'S LADDER is a rope ladder with wooden steps or spokes. It is also the name of a perennial plant with large blue flowers, which grows in bushy places in the north of England and south of Scotland.

JACOB'S STAFF is a mathematical instrument employed for taking heights and distances.

JACQUARD, JOSEPH-MARIE, was born at Lyons, on July 7, 1752, of humble parents, both of whom were employed in operations connected with weaving. His parents died, leaving him a small property, which he employed in the attempt to establish a business in the weaving of figured fabrics. The undertaking failed, and he was compelled to sell his looms in order to pay his debts. He subsequently married, and occupied himself with ingenious schemes for improvements in weaving, cutlery, and type-founding, which produced nothing for the support of his family. In 1792 he assisted in the defence of Lyons against the army of the Convention. Being denounced after the reduction of Lyons, he was compelled to fly. When he was enabled to return, and his native city began to rise from its ruins, Jacquard applied himself with renewed energy to the perfection of the beautiful apparatus for figured weaving bearing his name. [WEAVING.] He had conceived the idea of it as early as 1790, and now succeeded, though imperfectly, in accomplishing his end. His machine was presented, in 1801, to the national exposition of the products of industry, the jury of which awarded him a bronze medal for its invention. In the same year he obtained a patent, or 'brevet d'invention,' for a term of ten years.

About this time the attention of Jacquard was accidentally directed to the construction of a machine for weaving nets for fishing and maritime purposes. He accomplished the desired object, but having amused himself and his friends with his contrivance, he threw it aside. His machine-made net, however, fell into the hands of the préfet at Lyons, and the result was that, according to the arbitrary fashion of the time, he and his machine were placed under arrest and conveyed to Paris, where the invention was submitted to inspectors, amongst whom were Napoleon and Carnot, and a gold medal was awarded to him in February, 1804.

In 1804 Jacquard returned to Lyons, where he was long engaged in superintending the introduc-

tion of his inventions for figured weaving and for making nets, in which he was powerfully aided by Camille Pernon, a rich manufacturer. For some years Jacquard had to struggle against much opposition and prejudice on the part of the Lyonese weavers, who conspired to discourage the use of his machinery, and his personal safety was at times endangered. At length, however, the value of the invention was acknowledged, and it was brought very extensively into use, not only in France, but in Switzerland, England, Germany, Italy, and America. It is now, however, being superseded by looms of a more delicate and simple construction.

Jacquard continued to reside at Lyons, where he exerted himself in promoting the use of his great invention until, having lost his wife, he retired to Oullins, a village near Lyons, where he spent his latter years in retirement, and died August 7, 1834. During his life he received the cross of the Legion of Honour, and in 1840 a public statue was raised to his memory at Lyons.

JADE. [NEPHRITE; SAUSSURITE.]

JAEN, a province of Spain, with an area of 5179 square miles, and (at the last census) 845,879 inhabitants. It is a hilly district, but the soil in the valleys is extremely fertile. The produce is wine, oil, corn, honey, silk, vegetables, and fruits of every kind. The mountains abound with rich pastures; sheep and a fine breed of horses are bred in the country. *Jaen*, the capital of the province, is an episcopal town, and has two cathedrals and 18,054 inhabitants. It is most picturesquely situated, and surrounded by old Moorish walls, surmounted by numerous towers and pinnacles. The town was formerly noted for its silk manufactures, but they have entirely died out, and although situated in the midst of plenty it is now very poor. [ANDALUCIA.]

JAFFA. [SYRIA.]

JAFFNA, or JAFFNAPATAM, a town situated at the northern extremity of the island of Ceylon, is defended by a fort, regularly formed with five bastions, a broad moat, and a glacis. The town is about half a mile E. from the fort. The streets are regular, the houses neat and clean, and the population about 8000, mostly of Dutch descent. Jaffna has communication with the sea by a river. Ships unload in the roadstead, and the cargoes are conveyed to the town by boats. The trade is principally in tobacco and Palmyra timber. The town has long been an American mission station.

JAGGERY, the name given to sugar in its coarse state, as produced in the East Indies. It also refers to the inspissated juice of the Palmyra tree.

JAGUAR. [LEOPARDS.]

JAH, one of the titles of Jehovah.

JAIL FEVER. Prior to the philanthropic labours of Howard, the disease known as the jail fever was very prevalent in the prisons of England. It was caused principally by defective sanitary arrangements, and it often spread to persons in the court where the prisoners were tried. Such was especially the case at the fatal BLACK ASSIZE at Oxford in 1570; and even so recently as 1750 the lord mayor, aldermen, two judges, and many of the spectators were fatally infected with the disease at the Old Bailey assizes. It is not now considered

to have been a distinct malady, but merely a severe form of typhus fever.

JAINAS, or JAINS, a religious sect of the Hindoos. They are most numerous in the southern and western provinces of Hindustan, where they are principally engaged in commerce, and from their wealth and influence form a very important division of the population of the country. The history and opinions of this sect are also interesting from their striking similarity to the chief peculiarities of the religion of Buddha. They are divided into two sects, which have a great dislike to each other. They have many temples in Hindustan, one of which Bishop Heber was permitted to inspect. ('Journey to the Upper Provinces of India,' vol. i. p. 385.) The most complete account of the Jains is given by Professor Wilson, in his 'Sketch of the religious sects of the Hindoos.' ('Asiatic Researches,' vol. xvii.)

JALAP. The imports of Jalap into the United Kingdom in 1864 amounted to 45,344 lbs., value 9142*l.*, or about four shillings per lb. Mexico supplied 31,187 lbs. In the same year 87,563 lbs., value 7513*l.*, were exported. [CONVOLVULUS JALAPA.]

JALAPA, or XALAPA, is a city in Mexico, 50 miles W.N.W. of Vera Cruz. There are 12,000 inhabitants, who trade in maize, fruit, sugar, and honey, and manufacture some pottery. This city is built at an altitude of 4350 feet, and the medicinal weed *jalap* grows here wild, whence its name.

JALOOFS. [SENEGAMBIA.]

JAMAICA, one of the greater Antilles, and the most important possession of the British in the West Indies, extends from 76° 11' to 78° 19' W. long., and from 17° 45' to 18° 30' N. lat. Its length from E. to W. is nearly 150 miles, and its width may on an average be 40 miles. The entire area is about 6400 square miles, so that it is a little larger than Yorkshire. Its aboriginal name was Xaymaca, 'the land of wood and water,' which very fairly described its own aspect.

The surface of the island is very uneven. The eastern part is almost entirely filled up by the Blue Mountains, whose principal ridge occupies the middle of it, and runs nearly east and west. This range varies from 5000 to 6000 feet in elevation, and it has numerous offsets on each side. The western boundary of this mountain region is formed by a ridge which runs across the whole island from south-east to north-west, and rises in some places to a height of 4500 feet. The greatest plain in the island is that of Liguanea, which begins a few miles east of Kingston, and extends westward to a distance of about 30 miles; its average breadth is about 5 miles. Another level spot is the Plain of Vere, separated from the former by a low range of hills; and minor ranges exist in other parts of the island, which inclose numerous valleys.

The central heights are said to be remarkably favourable to longevity, and after having long been a sanitarium for the residents themselves, have lately begun to attract invalids from the United States. The rainfall varies in different years from 60 to upwards of 120 inches.

Near the central line of the island, the hills present the characteristics of the limestone formation, of which they consist. Caverns occur in several

places, and some of them are very extensive. The water which runs down from the hills forms small rivers; these flow for a short distance and then disappear in holes, and sometimes come again to the surface and again sink. These districts are only provided with running water during the rains, and the inhabitants are obliged to have recourse to tanks or cisterns, in which they collect the rain-water for the dry seasons. In other districts, Jamaica has the advantage of being well watered by numerous rivers, rivulets, and springs. None of the rivers are navigable except the Black River; but as Jamaica contains 500 miles of sea coast and nearly 100 harbours, bays, creeks, and coves, the want of river navigation is not much felt.

The climate of Jamaica is considered exceedingly hot; but this is only the case in the lower plains along the southern coast. Snow has never been observed, even on the most elevated peaks; hail is not a rare occurrence on them, but it melts as soon as it reaches the ground. There are two rainy and two dry seasons. The rains last from about May to July or August, and during October and November. The dry seasons occur between these periods. The July rains are most copious and long-continued, and are accompanied by excessive heat. Earthquakes are frequent; hurricanes less so than in the other West India islands.

The minerals of Jamaica are very numerous, consisting of the ores of iron, copper, lead, zinc, cobalt, and manganese, together with limestone, sulphate of barytes, iron pyrites, marble, gypsum, and lignite. Valuable quarries of lithographic stone were discovered in 1855, and traces of coal were also found.

The staple articles of the island are sugar, rum, and molasses, which form by far the most important articles of export. The sugar plantations are very numerous and extensive, especially in the lower and warmer tracts of the island. On the hills and their declivities coffee is cultivated to a great extent. Next to these the pimento plantations supply the most important article of export. Arrowroot, indigo, cotton, and cocoa were formerly much more cultivated than at present; ginger and turmeric are also produced, and a little tobacco. Indian corn is universally grown, and yields an abundant produce; two and even three crops of it can be raised within the year. Guinea-corn and rice are cultivated, as are also yams, cassava, sweet potatoes, artificial grasses, and a great variety of delicious fruits. The forests contain mahogany, satinwood, cedar, fustic, logwood, bamboo, cocoa, and various other trees.

The horned cattle are numerous. The horses are of a middle size, hardy and active, but only fitted for the saddle and harness. Mules are employed on the sugar estates. Sheep, goats, and hogs abound. All kinds of poultry are raised in the greatest abundance, excepting geese and ducks. The plantain, banana, sweet potato, &c., compose the principal food of the blacks.

Jamaica was possessed by the Spaniards from 1510 to 1655, and during the 150 years of their occupation the inhabitants, including Africans and Europeans, had not attained the number of 3000. Within about the same period of English rule (from 1655 to 1801) the number was 340,000—80,000 whites, 10,000 free people of colour, and 300,000

slaves. At the census of 1861 they had increased to 441,264, of whom only 13,816 were whites, so that there are at present thirty-two blacks to every white in the island. The two races have the same rights and privileges, and many of the coloured inhabitants were formerly members of the local legislature.

Since the passing of the Slave Emancipation Act the trade and productiveness of the island have very much declined, although it is only fair to add that even before the new order of things the commercial crops had been steadily decreasing. For instance, in the last three years of the slave trade, 1805–7, the quantity of sugar produced averaged fully 144,000 hogsheads; in the four years before the commencement of the abolition of slavery, 1831–34, it was under 91,000; in the four years of gradual abolition, 1835–38, about 70,000; and in the first four years of perfect freedom, 1839–42, less than 42,000. According to the returns of 1834 and 1863, the principal exports were as follow:—

	1834.	1863.
Sugar (cwts.), . .	1,500,000 ...	560,481
Rum (gallons), . .	2,697,324 ...	1,554,243
Pimento (lbs.), . .	3,605,400 ...	6,228,478
Coffee (lbs.), . .	17,725,731 ...	8,184,849

But while the exports have diminished, the imports, more particularly of food, have largely increased. In 1863 the value of all articles imported was 1,087,529*l.*, 581,227*l.* having been sent from England. The exports in the same year were 1,007,924*l.*, a decrease as compared with 1862 of more than 100,000*l.* In the article of sugar alone there was a falling off in value of 83,746*l.*, and in rum 57,319*l.*; but on the other hand there was an increase of 51,562*l.* in coffee.

Sugar plantations are now few in number as compared with former times; for, as the negro obtains with little exertion the means of subsistence from the bounty of nature, he is unwilling to devote himself to onerous agricultural toil. By the roadsides, on the edge of the wood and jungle, the gardens and provision grounds of the African may be seen (pleasant enough looking spots), where cocoa and bread-fruit trees are cultivated, with oranges, mangoes, plantains, and yams. Some of them pay a trifling rent, but the majority have squatted on the waste lands, asking no man's permission. So far has the disinclination of the freed negro to regular labour extended, that for many years coolies from Calcutta and liberated Africans have been introduced to work on the plantations. In 1863 there were altogether 4067 coolies and 1656 captured negroes in the island.

Jamaica is politically divided into three counties, Surrey, Middlesex, and Cornwall; it contains one city, Kingston, and thirty-three towns and villages. The counties are subdivided into parishes.

1. The county of Surrey extends over the eastern portion of the island, and contains Port Antonio, Morant Bay (the scene of the rising against the whites in 1865, suppressed with terrible severity), and the fine harbour of Kingston. Kingston is a considerable city, but exhibits many signs of decadence. It is regularly built, and contains many good houses, churches, charitable institutions, two Jews' synagogues, and schools. The greatest part of the

produce of the southern districts is sent here, and hence exported to Europe or America. The population is about 32,000. A railway from Kingston to Spanish Town was completed and opened in 1846. The harbour, a land-locked basin, available for the largest ships, is inclosed southward by a long tongue of land, at the extremity of which is *Port Royal* (15,000 inhabitants), once the capital of the island, which has been repeatedly destroyed by earthquakes, hurricanes, and fire, but is still a considerable place, as its harbour is the station for the ships of war, and it contains the naval arsenal, dockyard, and good fortifications. Morant Bay, between Port Royal and Morant Point, prior to the late insurrection, carried on a considerable trade. Antonio has a fort and a good harbour, but little trade. A cast-iron lighthouse has been erected on Morant Point, in lat. $17^{\circ} 56' N.$, long. $76^{\circ} 11' W.$

2. The county of Middlesex occupies the central part of the island. On its southern coast are Port Henderson and Old Harbour; but they are only visited by small vessels, which carry the produce of the country to Kingston. On the northern shores are Annotto Bay, Maria, and St. Ann's Bay, which carry on some commerce by sea. On St. Catherine's plain is built the town of S. Jago de la Vega, commonly called *Spanish Town*, which is considered the capital of the island, being the seat of government. It contains the governor's residence, the public offices, the superior law courts, and many institutions. The population is about 6000. The town is ill-built and unhealthy.

3. The county of Cornwall extends over the western part of the island. The two most frequented harbours on the southern shores, Black River and Savanna la Mar, have little trade; but on the northern coast are three thriving towns, *S. Lucia*, *Montego Bay*, and *Falmouth*.

Of the inhabitants of Jamaica, the Maroons were originally runaway slaves, partly from Jamaica itself, partly from Cuba, who lived in the forests on the northern side of the island. In 1738 a tract of land was granted to them in those parts, which they cultivated, and on which they built two small towns; and though a portion of them forfeited their privileges by a rebellion, others have preserved them to this day. They are loyal to the British government, but exhibit on all occasions a bitter hostility to the negro. No traces of the native population of the island existed when it was taken by the English from the Spaniards. In 1852 the cholera destroyed 40,000 of the population.

Jamaica was discovered by Christopher Columbus on his second voyage, the 3rd of May, 1494, but was not settled by the Spaniards before 1510. In 1655 it was taken from the Spaniards by the English, who for some time did not appreciate its value. Since 1655 it has remained in the undisputed possession of the British, but its internal peace has been seriously disturbed on several occasions. On February 22, 1745, about 900 negro slaves were detected in a conspiracy to destroy all the white inhabitants of the island. In 1795 the Maroons revolted, and were not reduced to subjection till March 11th, 1796. But the most alarming outbreak took place on December 22nd, 1831, when the island was placed under martial law, and most stringent measures and

numerous executions followed. In 1865 another negro insurrection took place in Morant Bay, in which many whites were most barbarously murdered; but owing to the prompt measures adopted the rising was speedily quelled. Its suppression, however, was attended with acts of cruelty and injustice which were considered to reflect discredit on the fair fame of Britain, and the voice of the British public loudly demanded a strict inquiry into all the circumstances attending the outbreak and termination of an *emeute* which seemed so mysterious. For this purpose a commission was appointed by the government to proceed to Jamaica, examine witnesses, and deliberately investigate the whole affair, and at the head of this commission was placed Sir Henry Storks, well known as an able and honest administrator. The result of their inquiries would seem to be, that the conduct of the island authorities was marked by deplorable severity, arising to some extent from an unjustifiable panic (1866), and that wanton and cruel excesses were unhappily committed both by the civil and military officials.

The executive was formerly in the hands of the governor, who, as well as the council, consisting of fifteen persons, was appointed by the Crown. The governor held the chief civil and military authority; his council constituted the Upper House. The Lower House, or the Assembly, was composed of forty-seven members, two from each of the parishes. Spanish Town, Kingston, and Port Royal sent one member each.

The political franchise was fixed at such a high rate that there were only about 2500 voters in a population of 440,000. It consisted, first, of a clear annual income (after paying all debts) of 150*l.* from lands held by voter or voter's wife; second, a clear annual income of 200*l.* arising partly from lands and partly from any income from office or business (deducting all charges or expenses of such office or business); third, a clear annual income of 300*l.*, arising from office or business; fourth, the payment annually of taxes to the value of 10*l.*

But this organization has been put aside by an Act of Parliament of the present session (1866), which vests the supreme authority in the hands of the Crown, and abolishes the houses of legislature. Jamaica will henceforth be administered as a Crown colony, by a governor solely responsible to the home authorities.

The supreme court in Spanish Town, and courts of assize in each county, sit three times yearly.

There is a bishop of Jamaica, whose see comprises the Bahamas and Honduras. Besides the clergy of the Established Church, who have the care of the several parishes, there are Scotch Presbyterian, Wesleyan, Baptist, and Moravian ministers.

The annual income and expenditure of the colony is each about 300,000*l.* per annum, besides which in 1863 England spent 156,660*l.* in military expenditure, as against 2845*l.* expended by the colony for the same purpose. The public debt of the island amounts to about 800,000*l.*

After being more than 200 years in the possession of Great Britain, the capabilities of Jamaica are still very inadequately developed. It has almost virgin sources of wealth and plenty in its pastures and its fisheries; and instead of buying, as it does, a large

share of its means of subsistence, it might either sell the same to others, or maintain twice or thrice its present population. This is due to the *régime* that has so long prevailed, and which placed the island entirely under the control of the planters; but it may be expected that the new government will inaugurate a new era—an era of commercial prosperity which will render this fertile island one of the brightest gems of the British crown.

JAMES I., King of Scotland, was a younger son of King Robert III. His elder brother, David, having been made away with, it is said, by the duke of Albany, the king caused James to be sent secretly to France, to preserve him from a similar fate. The vessel was taken by an English ship of war, and the prince carried prisoner to London. His father was so affected by the news that he died of a broken heart. The duke of Albany was thereupon made Regent of the kingdom. James, now in the thirteenth year of his age, was on April 14, 1405, conducted to the Tower, and he afterwards resided in Nottingham Castle and in Windsor Castle, where he first saw and loved Lady Jane Beaufort, whom he afterwards married, and whose charms he has celebrated in his 'King's Quhair.' Henry IV. caused him to be well educated, and in 1417 Henry V. took him with him on his second expedition to France. The duke of Albany died in 1419, and from that time measures began to be taken seriously for his release. He ascended the throne in 1424, and immediately took active measures to restore the kingdom to order, by putting a check to the ambition of the Albany family and its adherents. He also adopted wise provisions for the government of the country, and ordered the statutes of Parliament, for the first time, to be regularly enrolled. At a later period of his reign James evinced great energy and promptitude in suppressing the disturbances in the Highlands and Isles. The rebels made an unconditional surrender, and the Lord of the Isles was obliged to make his submission on his bended knees at Holyrood House.

The king's vigour and determination proved so obnoxious to the nobles, that they formed a conspiracy against him, under the duke of Athol, the king's uncle, and on February 21, 1437, he was murdered, in the forty-fourth year of his age.

James was distinguished for his literary and poetic talents: three pieces of his have come down to us, 'Christ's Kirk on the Green,' 'The King's Quhair' (or book), and 'Peebles at the Play,' all displaying considerable intellectual power, and much humour.

JAMES II., King of Scotland, only son of James I., succeeded to the crown when about seven years old. The turbulence of the nobles, to which his father fell a sacrifice, continued undiminished throughout his reign, and he was little more than a tool in the hands of a faction. To add to the calamities which the country suffered, it was visited by plague and famine. The king was also attacked from England, and at the siege of Roxburgh, which was occupied by the English, he was killed by the bursting of a cannon. This was in the year 1460, and in the twenty-ninth year of his age.

JAMES III., King of Scotland, was, like his father James II., about seven years old at his accession to the throne, August 3, 1460. He had to contend at the beginning of his reign with the Lord

of the Isles, who allied himself with Edward IV. of England for the conquest of the kingdom. While this rebellion convulsed the north, the minor offices of magistrates and common-councilmen in the several burghs were objects of tumultuous contest; and the Act 1469, c. 29, was passed, the foundation of the *close system* that existed till the Burgh Reform Act for Scotland. The king appears to have been the slave of his ecclesiastics, and attached to low favourites, who involved him in a quarrel with his son and his nobles, terminating in the encounter at Bannockburn. The king fled from the field, and falling from his horse was, it is stated, killed, and his body carried off, nobody knew where. This happened in June, 1488, in the thirty-fifth year of his age.

JAMES IV., King of Scotland, son of James III., was about fifteen years old at his accession to the throne, June 11, 1488. He was of an active disposition, and the commerce and literature of the country flourished under his encouragement. But he became melancholy and superstitious, and in 1494, by the direction of the pope's legate, bound about his waist an iron belt, to be worn day and night for the remainder of his life, as a penance for his participation in the rebellion against his father. In 1512 a great council of the clergy was held at Edinburgh, where the famous *Valor Beneficiorum*, called 'Bagimont's Roll,' was made up. The following year, the king, taking up the French cause against the English, entered, with the flower of the kingdom, on the fatal field of Flodden, where he was slain.

JAMES V., King of Scotland, son of James IV., was little more than a year old when the crown devolved upon him, in 1513. The regency of the young king was long an object of ambition. The slaughter of so many noblemen at Flodden had, however, given a decided advantage to the clergy. Gavin Dunbar, who had been the king's preceptor, was made archbishop of Glasgow in 1524; in 1528 he was appointed lord chancellor; and in four years afterwards the Court of Session was erected—a court of general and supreme jurisdiction under the chancellor. When Cardinal Beaton succeeded to that office, its vast powers were exercised with such force as to threaten the extermination of every authority in the kingdom but his own and the papal. Much discontent was hence created, and in the course of a war which ensued with the English, the Scottish barons and their troops refused to obey the orders of the king, and attack the enemy, but, on the contrary, 10,000 men surrendered without striking a blow. These vexations had such an effect on James, that he died in the thirty-third year of his age, in December, 1542, leaving a daughter, the unfortunate Mary Stuart, only a few days old. James patronized literature and architecture, and is said to be the author of one or two songs yet popular in Scotland.

JAMES I. of England, and VI. of Scotland, the only offspring of Mary, queen of Scots, by her second husband Henry Stuart, Lord Darnley, was born in the castle of Edinburgh, 19th June, 1566. The murder of Darnley took place February 18, 1567, and was followed by Mary's marriage with Bothwell, and her forced resignation of the crown in favour of her son, who was crowned at Stirling on the 29th

of June, 1567, as James VI., being then little more than a year old.

Before his mother's marriage with Bothwell he had been committed by her to the care of the earl of Mar, who had retired with his charge to Stirling Castle. Here he continued to reside during the regencies of the earl of Murray, of the earl of Lennox, of the earl of Mar, and of the earl of Morton. Morton was compelled to resign the regency at Edinburgh, March 10, 1578. Affairs were now nominally administered by the king, assisted by a council composed of twelve of the nobility. The new government, however, soon became unpopular, and Morton contrived to regain his former power. But in the midst of his success the regent was accused by the king's favourite, Esmé Stuart, brother of the earl of Lennox, and Captain James Stuart, afterwards created earl of Arran, of having been accessory to the murder of Darnley. He was immediately committed to prison, and, after trial, executed at Edinburgh, June 2, 1581. The two favourites then became the rulers of the kingdom. In August, 1582, occurred the Raid of Ruthven, the immediate consequences of which were the expulsion of the favourites, and the restraint, amounting to imprisonment, of the king, by the faction headed by the earls of Mar, Gowrie, and Glencairn, Lord Lindsay, and others, for about ten months. At last, having been permitted to go from Falkland to St. Andrews, June 27, 1583, he contrived, with the assistance of some friends, to throw himself into the castle there, and to maintain his position till his enemies gave up the contest. One of the king's first acts after he recovered his liberty was to release Arran, and again to commit to him the management of affairs. Though James had visited Gowrie and granted him a pardon, yet he now caused him to be executed. On the 29th July, 1585, a treaty of intimate alliance was concluded between Queen Elizabeth and the Scottish king, and an annual pension of 5000*l.* was settled by the queen upon James. Through the instrumentality of a new court favourite, the eldest son of Lord Gray, Elizabeth now sought to overthrow Arran. With her connivance, the lords who had been banished on account of the Raid of Ruthven entered Scotland at the head of a force of 10,000 men, in the end of October, 1585. Arran and his late associates were all dismissed from power, he himself being besides stripped of his titles and estates. The new settlement of the government was followed by the conclusion, July 8, 1586, of another treaty offensive and defensive with England.

In October of the same year, the unfortunate Mary, after her imprisonment of nearly twenty years, was at last brought to trial, and on the 8th of February following she was put to death. Between her condemnation and her execution, James made considerable exertions to save her, but was very soon pacified, and continued on the same terms of friendship with Elizabeth as before. Gray, however, who had betrayed James' interest at the English court, where he had been sent to negotiate on behalf of Mary, was disgraced and dismissed.

In 1589, James was married to the Princess Anne, the second daughter of Frederick II., king of Denmark. He proceeded in person to Upsal in

Norway, and did not return to Scotland till May 20, 1590. The first memorable event that then occurred was a daring attempt by his relation, Francis Stuart, lately created Earl of Bothwell, a grandson of James V. by his son John, prior of Coldingham, who collected a force of his retainers, and on the night of December 27, 1591, entered Holyrood House, set fire to several of the apartments, and had nearly made his way to the king's chamber; he failed, but succeeded in making his escape, and fled to the north. Bothwell and all his adherents were soon after attainted in Parliament. In the beginning of 1593, a new conspiracy of Huntly and the other heads of the popish faction was detected; and a few months later, Bothwell, having failed in another attempt to seize the royal person at Falkland, suddenly returned from England, where he had been protected by Elizabeth, and on July 24, 1593, entered the palace with a band of armed followers, and made the king his prisoner. James was obliged both to grant a full pardon to the traitor and to dismiss the Chancellor Maitland and his other chief ministers; and he remained in durance till the beginning of September. Disturbances, however, were again and again excited in the course of this and the two following years by the factions of Bothwell and the popish lords, who, at length joining their forces under the conduct of the earls of Huntly and Errol, encountered the royal army, commanded by the earl of Argyll, at Glenlivet in Aberdeenshire, October 3, 1594, and put it completely to the rout. But in consequence of an expedition into the northern districts, conducted by James in person, the popish lords were forced to make their submission, and allowed to retire beyond seas. Bothwell fled to France, from whence he withdrew to Italy, where he professed himself a convert to popery, and spent the rest of his days in obscurity and indigence.

These commotions had scarcely been quieted when James became involved in new troubles in consequence of a contest with the clergy of the Presbyterian church, which had been established as the national form of religion by an act of the Scottish Parliament in 1592. By an unusual exertion of vigour and firmness James was enabled to crush the insurrection, and to turn the occasion to account in bringing the church into full subjection to the civil authority. In the course of the following year, 1598, the substance of episcopacy, in a political sense, was restored by seats in Parliament being given to about fifty ecclesiastics on the royal nomination. Even the General Assembly was gained over to acquiesce in this great constitutional change.

The most memorable event in the remainder of James' Scottish reign was the very mysterious affair known in history by the name of the Gowrie conspiracy, an attempt to seize the king, by Alexander Ruthven, a younger son of that earl of Gowrie who was executed in 1584.

James at length became king of England by the death of Elizabeth, March 24, 1603. The conspiracy of Sir Walter Raleigh, Lord Cobham, and others, to place on the throne the Lady Arabella Stuart, James' cousin, was the first affair of interest. The next was the settlement of the disputes between the Church and the Puritans. James' first Parlia-

ment met on March 19, 1604. In his speech to the House he zealously urged the union of England and Scotland into one kingdom; but nothing came of this proposal for the present. James, however, of his own authority, now assumed on his coins and in his proclamations the title of king of Great Britain.

Peace with Spain was concluded August 18, 1604. The great event of the year 1605 was the Gunpowder Plot. [FAWKES, GUIDO.] In 1612, the death of James' eldest son, Henry, prince of Wales, in the nineteenth year of his age, spread a general grief through the nation.

The death of Prince Henry was followed, February 14, 1613, by the marriage of James' daughter, the Princess Elizabeth, with Frederick the Elector Palatine. James caused great discontent in the country by the favourites whom he successively encouraged. Of these the chief were Carr, or Ker, earl of Somerset, who married the countess of Essex, and, together with her, was convicted of the murder of Sir T. Overbury; and George Villiers, who, after having been knighted, was created successively Earl of Buckingham, Marquis of Buckingham, and Duke of Buckingham, and who continued to be the first favourite and ruling minister during the remainder of the reign. [BUCKINGHAM.]

In the summer of 1617 James paid a visit to Scotland, and having summoned a Parliament, succeeded in obtaining the assent of that body, and also of the General Assembly, to such regulations as brought the Scottish church very nearly to the model of the English.

The year 1618 was disgraced by the execution of Sir Walter Raleigh. The public indignation at the king's subserviency to the court of Spain was roused to a high pitch by the events of the two following years. Austria, assisted by Spain, attacked the Bohemians, who had chosen the Elector Palatine for their king, and James refused to take part with his son-in-law and the Protestant interest on the Continent, and even to acknowledge his new regal title. In the Parliament which was called in 1621 after an interval of six years, memorable among other things for the impeachment of Bacon [BACON, FRANCIS], the first decided step was taken by the Commons in their contest with the crown by their famous protest, passed December 18, 1621, in reply to the king's assertion that their privileges were derived from the grace and concession of his ancestors and himself,—‘That the liberties, franchises, and jurisdiction of Parliament are the ancient and undoubted birthright and inheritance of the subjects of England.’ This resolution, which the king tore from the Journals with his own hand, was followed by the immediate prorogation and soon after by the dissolution of the Parliament, several of the leading members of the House of Commons being at the same time sent to the Tower or to other prisons. As the public clamour for the recovery of the Palatinate still continued, another Parliament was assembled in February, 1624, which eagerly granted supplies for the attainment of that object by force of arms; war was in consequence declared against Spain, and an army under Count Mansfeldt was sent into Germany in the latter part of the year. But this expedition turned out an utter failure.

James' reign of nearly fifty-eight years in Scot-

land, and rather more than twenty-two in England, was terminated by his death on March 27, 1625.

His children by his queen, Anne of Denmark, born 12th December, 1574, married 24th November, 1589, died 2nd March, 1619, were:—1. Henry Frederick, born at Stirling Castle, 19th February, 1594, died 6th November, 1612; 2. Robert, died in infancy in Scotland; 3. Charles, who succeeded his father as king; 4. Elizabeth, born 19th August, 1596, married to Frederick V., Elector Palatine, 14th February, 1613, died 8th February, 1662; and three daughters who died in infancy.

James I. was a voluminous author; his works have been partially enumerated by Harris, in his ‘Historical and Critical Life,’ and by Horace Walpole, in his ‘Royal and Noble Authors;’ but the fullest account that we have met with is given by Dr. David Irving, in his ‘Lives of the Scottish Poets.’ A collected edition of his works was published in folio, in 1616, by James Montague, bishop of Winchester. The best known are his ‘Counterblast against Tobacco’ and Treatise on Witches. It ought not to be forgotten that the authorized translation of the Bible was commenced and completed under his auspices.

The character of this monarch has been the subject of much critical discussion, the general result of which is decidedly unfavourable. The reader may compare the elder D'Israeli's vindication with the works of Lingard, Froude, Hallam, Mignet, and Agnes Strickland.

JAMES II. of England, and VII. of Scotland, was the second surviving son of Charles I. by his queen, Henrietta Maria of France, and was born October 15, 1633. He was immediately declared duke of York. After the surrender of Oxford to Fairfax in June, 1646, the duke, his younger brother Henry, and his sister Elizabeth, were committed by Parliament to the care of the earl of Northumberland. They continued under his care till April 21, 1648, when the duke made his escape from St. James' Palace, and took refuge in Holland with his sister Mary, princess of Orange. After various adventures and changes of locality, he settled at Paris; and here he chiefly resided till he attained his twentieth year, when he received a command in the French army, and served under Marshal Turenne. The peace concluded with Cromwell, however, in October, 1655, compelled him, with his elder brother, to quit France; upon which he retired to the Low Countries, and entered the Spanish service under Don John of Austria.

At the Restoration (May, 1660) the duke of York returned to England with the king, and was made lord-high-admiral and lord-warden of the Cinque Ports. In September, 1660, he secretly married Anne, the eldest daughter of the Chancellor Hyde. [HYDE.] In promoting the war with Holland he was very active, and assumed the command of the fleet, which he eventually resigned, as well as his office of high-admiral, on the passing of the Test Act, which required all officers, civil and military, to receive the sacrament according to the usage of the Established Church. On November 21, 1673, the duchess of York having died two years previously, he married Mary Beatrice Eleanora, daughter of Alfonso IV., duke of Modena, then only in her fifteenth year.

On November 4, 1677, the duke's daughter Mary, then in her sixteenth year, was, greatly to the public satisfaction, married to her cousin William, prince of Orange.

During the excitement produced by Titus Oates' Popish Plot, in 1678-79, the duke of York, by the advice of his brother, retired to the Continent. While he was absent, the famous bill for his exclusion from the throne was twice read in the Commons, and ordered to be committed, by large majorities, and was only prevented from being passed in that House by the prorogation of the Parliament, May 27, 1679. On his return he became involved in the discreditable affair of the Meal Tub Plot. The share which he had in this business only added to the dislike in which he was held by the great body of the nation, and which was still further increased by the severity of his administration of affairs in Scotland. On again taking up his residence at the English court, he became his brother's chief counsellor, and, much more than Charles himself, the mainspring and director of the conduct of public affairs. To his instigation are chiefly attributed the general attack upon corporations, the executions of Russell and Sidney, and the other violent and despotic acts of the two closing years of Charles' reign. A new exclusion bill which had been brought into the House was twice defeated by the dissolution of Parliament.

On the death of his brother, February 6, 1685, no opposition was made to the accession of James. His first act was to issue a proclamation ordering the customs and excise duties to be paid as usual; he went openly and in great state to the illegal celebration of the mass, and lost no time in sending an agent to Rome to make his submissions to the pope.

He determined, however, to call a Parliament, as he said, simply to humour the English people, he himself being at the same time resolved to make himself independent of its authority, and to dissolve it when it opposed his wishes. In reply to an indirect appeal to the French king, that monarch transmitted to James 500,000 livres, and it was readily agreed, in requital, that the chief obstacle in the way of the seizure by the French king of the Spanish Netherlands should be removed, by the existing treaty between Spain and England being held to have terminated with the death of Charles.

These details of its commencement supply the key-note to the whole course of James' disgraceful reign. The Parliaments of England and Scotland met, and responded with the utmost submission to all the king's demands. While they were sitting, both England and Scotland were invaded, the former by the duke of Monmouth, the latter by the earl of Argyre, both of whom had for some years been exiles in Holland. Argyre, after the dispersion of his few followers, was apprehended and executed at Edinburgh, on June 30, 1685. Monmouth was defeated July 5, in the decisive battle of Sedgemoor, and, being two days after found concealed in a ditch, was brought to London, and delivered to the executioner on the 15th of the same month. The suppression of Monmouth's insurrection was followed by the savage military vengeance of Colonel Kirke, and the more revolting enormities of the western 'campaign,' as it was jocularly called by the king, of Chief-justice Jeffreys.

Among the arbitrary measures next taken by James, on his own individual authority, were—the abandonment of the legal test of conformity with the Established Church, and of the penal laws against Dissenters; the extinction of the liberty of the press; the bestowal of nearly all public employment upon Catholics; the sending of an ambassador, the earl of Castlemaine, to Rome; and the reception of a nuncio from the pope. To some of these measures Parliament offered a feeble resistance, while others were quietly submitted to; but on the publication of a second declaration of indulgence to Dissenters, April 27, 1688, which was commanded to be read by the clergy immediately after divine service in all the churches, Sancroft, archbishop of Canterbury, and six bishops, Lloyd of St. Asaph, Ken of Bath and Wells, Turner of Ely, Lake of Chichester, White of Peterborough, and Trelawny of Bristol, met in the archbishop's palace at Lambeth, May 18, and drew up a petition to the king, representing their aversion to obey the order. For this they were all, on June 8, sent to the Tower, and afterwards, on the 29th, brought to trial before the Court of King's Bench, on the charge of publishing a false, fictitious, malicious, pernicious, and seditious libel, when a verdict of Not Guilty was pronounced by the jury, which was received with acclamations by the whole kingdom. This defeat, however, in no degree checked at the moment the infatuated king. He issued orders to prosecute all those clergymen who had not read his declaration, that is, the whole Church of England, two hundred excepted; he endeavoured to force a Roman Catholic president on Magdalen College, Oxford; and in the midst of this great contest with the Church and the nation, on June 10, a son was announced to have been born to James.

James' son-in-law, the prince of Orange, had not been an unobservant spectator of what was passing in England; and to him the hopes of the English people were now very generally turned. In compliance with the invitation of the heads of the parties in the state, he landed, November 5, 1688, with about 14,000 men, at Torbay in Devonshire. Before the end of that month James found himself nearly deserted by everybody. In the night of December 12, having previously sent over the queen and the young prince to France, he embarked with a single attendant in a boat at Whitehall Stairs, from which he was forced the next day to land at Feversham, and thence returned on the 16th to Whitehall. On the 17th the prince of Orange, having arrived in London, desired James to leave the palace: he proceeded to Rochester, and on the 23rd embarked on board a frigate, and was conveyed to Ambleteuse in Brittany. Thence he repaired to St. Germain's, where Louis XIV. gave him the château of St. Germain's for his residence, and bestowed on him a small revenue.

Meanwhile the English crown was settled upon the prince and princess of Orange as King William III. and Queen Mary. [WILLIAM III. and MARY.] In the beginning of March, 1689, James sailed from Brest, landed at Kinsale, and immediately marched to Dublin, with a small force supplied by the French king. A few weeks after he laid siege to Londonderry, which, however, he was not able to reduce. After various military operations, his cause was

finally ruined by the defeat he received from King William in person at the battle of the Boyne, fought on July 1, 1690. He soon afterwards returned to France, and resided at St. Germain's till his death, September 6, 1701.

By his first wife, Anne Hyde, James II. had eight children, all of whom died young except MARY and ANNE, afterwards queens of England. By his second wife, Mary of Modena, he had James Francis Edward, prince of Wales, styled the elder Pretender, born June 10, 1688, died at Rome, December 30, 1765; one son, Charles, who died an infant; and four daughters. He also left several illegitimate children, the most distinguished of whom was James Fitz-James, duke of Berwick.

The principal portion of the papers formerly belonging to the Stuart family, which were obtained by George IV. when regent, has been printed under the title of 'The Life of James the Second, King of England, &c., collected out of Memoirs writ of his own hand; together with the King's Advice to his Son, and his Majesty's Will. Published from the Original Stuart Manuscripts in Carlton House, by the Rev. J. S. Clarke, LL.B., F.R.S., Historiographer to the King, Chaplain of the Household, and Librarian to the Prince Regent.'

JAMES, GEORGE PAYNE RAINSFORD, a most voluminous and popular writer of novels, was born in London in 1801. His father was a physician. At an early age G. P. R. James commenced authorship by some anonymous contributions to the press. In 1822 he wrote a 'History of the Black Prince,' and in 1825 his first and best novel, 'Richelieu,' which was so favourably received by the world of novel readers that the author soon sent forth a second venture, 'Darnley.' Thenceforth, for a period of more than thirty years, a ceaseless flow of romantic fiction issued from the literary workshop of this prolific novelist. In the reign of William IV. James was made historiographer of Great Britain, a post which he afterwards resigned. The grounds of such an appointment may possibly be found in his 'History of Charlemagne,' 1832, 'Life and Times of Louis XIV.,' 1838, and 'Richard Cœur de Lion,' 1841. He also wrote four of the five volumes in Lardner's Cyclopædia containing 'Lives of Foreign Statesmen.' The principal of his novels, in addition to those already mentioned, are, 'Gipsy,' 'De L'Orme,' 'Philip Augustus,' 'Henry Masterton,' and 'Mary of Burgundy.' In 1850 he was appointed British consul for the state of Massachusetts, and in 1858 consul-general at Venice for the Austrian ports in the Adriatic. In that city he died, 9th May, 1860.

JAMES, JOHN ANGELL, an eminent Independent minister, was born at Blandford, Dorset, in 1785. He studied for the ministry at Gosport academy, and in 1805, at the early age of twenty, was ordained to the pastoral charge of Carr's Lane Chapel, Birmingham, where he remained till his death, October 1st, 1859. He was one of the most celebrated and influential of the nonconformist ministers of his day. He took a prominent part in all religious and benevolent enterprises, and was a most zealous and liberal supporter of educational and missionary schemes; but his most conspicuous service to the cause of religion was rendered by his

VOL. VII.

numerous works, which have obtained a vast circulation. His 'Anxious Inquirer' has been translated into all the continental languages, and has probably been more extensively read than any other English work except the Pilgrim's Progress. The jubilee services which commemorated the completion of the fiftieth year of Angell James' ministry in 1855, afforded a striking proof of the estimation in which he was held, not only by his congregation and fellow-townsmen, but by the evangelical clergy of the Church of England and dissenters of all denominations.

JAMES' PALACE, ST., was originally a hospital for lepers, and made by Henry VIII. a sort of adjunct to Whitehall, the Park (which he inclosed) connecting both. Very little of the original palace remains except an ugly gate-tower and a Gothic fireplace. Everything else has been patched up in brick, very barbarously as regards the exterior, though the chief apartments are found to answer better than those of Buckingham Palace for holding drawing-rooms and levees, almost the only purpose to which this building is now applied. The British Court is usually called the Court of St. James'. The park adjoining the palace contains 87 acres, and has during the last few years been so much improved as to render it one of the greatest ornaments of London.

JAMES' POWDER. A diaphoretic medicine, consisting chiefly of antimonious acid and phosphate of lime.

JAMES RIVER. [VIRGINIA.]

JAMES, SAINT, THE EPISTLE OF, one of the books of the New Testament. There are at least two individuals of the name of James mentioned in the New Testament.

1. *James*, one of the apostles, son of Zebedee, and brother of the Apostle John, who was chosen with Peter and John to accompany Christ to the Mount of Transfiguration. He was beheaded at Jerusalem by order of Herod Agrippa, about A.D. 44. He could not have been the author of the epistle, since it bears marks of being written at a later period.

2. *James 'the Less'* as he is called in Mark xv. 40, the son of Alphaeus and Mary, was also one of the apostles.

There is likewise mentioned in the New Testament a James, a brother of Jesus (Matt. xiii. 55; Mark vi. 3), who is generally admitted to be the same person as James the Less, for the Greek word translated 'brother' was often used in the sense of 'cousin.' The epistle is almost universally attributed to this James by the Fathers and modern critics; it was probably written shortly before he was put to death by Ananias the high priest, about A.D. 62 or 63.

JAMESONE, GEORGE, called by Walpole the Vandyck of Scotland, was the son of Andrew Jamesone, an architect, and was born at Aberdeen in 1586. Jamesone and Vandyck were about 1616 fellow pupils of Rubens at Antwerp. When Charles I. visited Edinburgh in 1633, he sat to Jamesone, and presented him with a diamond ring from his own finger. His career is not exactly known, but it must have been a successful one, for he left his wife and family well provided for at his death in 1644; and he bequeathed also much in other directions.

H II

JAN MAYEN, an island in the Arctic Polar Sea, lying between $70^{\circ} 49'$ and $71^{\circ} 9' N.$ lat., and between $7^{\circ} 26'$ and $8^{\circ} 44' W.$ long. It extends from south-west to north-east about 30 miles, and is in no place above 9 miles in breadth. On the northern extremity, where the island is widest, stands the mountain called Beerenberg or Bear Mountain, a snow-capped peak rising to 6870 feet above the sea-level. Even in the beginning of August all the high lands are covered with snow and ice. The coast has several roadsteads with good anchorage in 5 to 10 fathoms water, black sandy ground, but no harbour for a ship. There are foxes and white bears. Water-fowl are numerous. The vegetation is very scanty, and limited to a few plants scattered widely about among the volcanic minerals. The island was discovered in 1611 by a Dutch navigator called Jan Mayen, and was much visited up to about 1640 on account of the great number of whales, which, however, afterwards retreated to other parts of the Arctic Sea. A graphic account of it occurs in Lord Dufferin's 'Letters from High Latitudes.'

JANEIRO, RIO DE, the capital of the empire of Brazil, is situated in $22^{\circ} 54' S.$ lat., $43^{\circ} 9' W.$ long., on the western shores and near the entrance of the Bay of Rio de Janeiro, which extends N. and S. a length of 17 miles, with a breadth of from 4 to 11 miles, and, being inclosed by high hills, forms perhaps the finest, safest, and most capacious harbour in the world. The entrance to the bay, which is about a mile in width, is defended by batteries and fortresses erected on the promontories on each side and on the island of Lagam.

The town extends along the shore about 3 miles on an undulating plain, the highest point of which is crowned with the church of Nossa Senhora da Gloria. The hills which surround the city are composed of gneiss, intersected by veins of granite. Only a small extent of the town stands S. of the hill da Gloria; the principal part is built north of this hill, on a rocky shore opposite the island das Cobras.

Rio possesses no imposing street architecture, but has some good public buildings in the European style. The private houses are not outwardly attractive, but villas in the environs evince great taste, and are rendered extremely lovely by tropical flowers, fruits, and foliage. An aqueduct 7 miles in length brings water to the city, and fountains are numerous. Churches and convents crown the top of almost every hill, but their condition proclaims the relaxed hold of the Roman Catholic faith on the population, which is also very apparent in every part of Brazil. Some have remained unfinished for half a century; others are dilapidated, and not a few are deserted. There are several public institutions for the sick and destitute, a theological seminary, a medical college, several banks, military and naval academies, the college of Don Pedro II., a national university, and the national library, containing 120,000 volumes, chiefly brought over from Lisbon. The English residents also have an extensive and valuable library, and a Protestant chapel, built in 1823.

Rio is so placed as to be deprived of the benefit of the land breeze by a range of mountains, and is exposed to suffocating heat, relieved only by the sea breeze in the middle of the day. The mean temperature of the year is 73.7° Fahr.

Rio de Janeiro contained a population at the last census of 296,136—comprising 77,989 native whites, 36,329 white strangers, 10,722 free coloured, and 78,835 slaves. Most of the inhabitants are engaged in commerce. There are numerous sugar refineries, tanneries, cotton factories, rum distilleries, train-oil factories, and diamond-cutting establishments.

The commerce of Rio is extensive, and on the increase. The principal exports are cotton, coffee, sugar, hides, rice, tobacco, rum, tapioca, ipecacuanha, timber, manioc flour, gold, diamonds, &c. The imports, more than one-half of which in value are derived from Great Britain, and nearly half of the remainder from France, include cotton, woollen, linen, and silk manufactures, wines, ironmongery, flour, meat, fish, butter, spirits, earthenware, paper, &c. The value of the whole in 1863 was 5,582,431*l*. The number of vessels which arrived at the port in the same year was 3000 (496,616 tons), and the departures 2980 (572,780 tons.) These figures are exclusive of the mail steamers from Southampton and Bordeaux. The total value of the exports in 1863 was 5,899,538*l*. The following are the chief articles:—Coffee, 1,350,109 bags of about 160 lbs. each; sugar, 9722 boxes; rum, 2734 pipes; horns, 283,237; hides, 63,944; tobacco, 23,907 packages. The countries which took the largest quantities were Great Britain, France, and the United States.

The British Consul at Rio, in his report for 1865, says that 'the city has progressed enormously in wealth and material improvement during the last twelve or fifteen years; indeed, I may well date that improvement from the final cessation of the African traffic in slaves. The large capital once directed to the barter and sale of human flesh in Africa has been more profitably employed at home; for when once that iniquitous trade no longer offered a safe investment to the men-stealers, the spirit of enterprise, as well as the improvement of the country, more especially of this capital, was commenced, and has ever since been vigorously prosecuted.' Several railways constructed by English labour already connect Rio with the interior, and others are in course of construction. The city also possesses eight steamboat companies, plying daily to various ports situated within the bay; four companies doing provincial coasting service; and the Brazilian Steam Navigation Company, carrying the mails twice a month to all the northern ports as far as Para, and a branch also twice a month to Rio Grande do Sul and Monte Video. The Rio de Janeiro City Improvements Company was established in London in 1862 with a capital of 850,000*l*, for the drainage of the city, and already several thousand houses have been completed.

Rio was first founded as a French colony in 1556, with the name of San Sebastian. It was intended to be the capital of a region to be called Antarctic France, but little more than ten years elapsed before the Portuguese took possession of the settlement.

Near Rio de Janeiro, and connected with it by railway, is the town of Petropolis, which has become important as the summer residence of the emperor, and most of the diplomatic body and the wealthier citizens. It is about 2500 feet above the level of the sea, surrounded with hills covered with the virgin forest. The population is 10,000.

(See Gardner, *Travels in Brazil*; Von Spix and

Von Martins, *Travels in Brazil*; Cazal, *Corografia Brazilica*; Hincheliff, *South American Sketches*; *Consular Reports*; Captain Burton, in *Frazer's Magazine* for 1865-66, &c.)

JANIZARIES, or JANISSARIES, is the name of a Turkish militia, once formidable, but now extinct. The origin of this body dates from the reign of Amurath, or Murad I., who, after having overrun Albania, Bosnia, Servia, and Bulgaria, claimed the fifth part of the captives, from among whom he chose the young and able-bodied, and had them educated in the Mohammedan religion, and for the military profession. Until the death of Solymán the Magnificent, the Janizary body was recruited exclusively from captives, but after that time by enrolment of Osmanlees. By the original laws of their body the Janizaries could not marry; the prohibition was at first evaded, and at last totally disregarded. They were formidable to the government from their numbers and union. They repeatedly mutinied against the sultans, and obliged them to change their ministers, or even deposed them. In more recent times they dethroned Selim; and in the beginning of the reign of the Sultan Mahmood they broke out into a dreadful insurrection which lasted three days. At last Mahmood resolved to abolish them, and issued a proclamation accordingly. A general attack was made upon them in May, 1826, in which about 25,000 are said to have perished. MacFarlane, in his 'Constantinople in 1828,' gives a vivid account of this catastrophe.

JANSENISTS, a sect which appeared in the Roman Catholic Church about the middle of the seventeenth century. They took their name from Janssen, or Jansenius, bishop of Ypres, in France, who published a book entitled 'Augustinus,' certain propositions in which, relating to Grace and Predestination, were decided to be heretical, and were condemned by a bull of Pope Innocent X., in the year 1653, as impious and blasphemous. The doctrine of the Jansenists was somewhat similar to that of Calvin, and they appealed to the writings of St. Augustine as their authority. A great controversy ensued, which caused a schism in the church. The persecutions with which the Jansenists were visited made many fanatics, but the paroxysm subsided after a few years, and Jansenism, as a sect, never afterwards revived, although they still have a few churches at Utrecht and Haarlem.

JANSEN, CORNELIUS, was born at Amsterdam, and lived several years in England. He was employed by King James I., and painted several fine portraits of that king and of his children, as well as of the principal nobility. His colouring is clear and natural; the carnations are soft, and except in freedom of hand and in grace, he was esteemed equal to Vandyck. He died in 1665.

JANSENS, ABRAHAM, born at Antwerp in 1569, was a competitor with Rubens. In colouring he was only inferior to that painter. His compositions are spirited, his drawing correct, his pencil decided, and his draperies natural.

JANSENS, VICTOR HONORIUS, born at Brussels in 1664, was for four years painter to the duke of Holstein, by whom he was sent to Italy, where he took Albano for his model, and became superior in his own style to all his contemporaries.

Most of the palaces and churches of his own country are adorned with his compositions. He died in 1739.

JANTHINA, or IANTHINA, Lamarck's name for a genus of turbinated testaceous molluscs. Cuvier assigns to the *Janthina* a place among his *pectinibranchiate Gastropods*, between the *Pyramidellæ* and the *Neritæ*.

Omitting the anatomical characters of the mollusc, the generic characters may be thus detailed:—Shell ventricose, globular or conoid, very fragile, with a low spire, and the last whorl larger than all the rest together; aperture large, subtriangular, with disunited borders; the columella straight and long, forming the whole of the left border or lip, right border or lip trenchant, and often notched in the middle; colour of all the species hitherto discovered violet, more or less intense. Operculum modified into a vesicular appendage, which serves to suspend the animal at the surface of the water, and which adheres to the posterior and fleshy part of the foot.

Geographical distribution very extensive, the form having been met with in the four quarters of the world, floating on the ocean or driven on the shores by tempests. It has occurred on the coasts of our islands; but there is reason for thinking that it is not to be found in very cold latitudes. In warm climates it is very plentiful.

Examples, *Janthina fragilis* and *Janthina globosa*.

JANUARIUS, ST., a martyr of the Christian faith in the latter part of the third century. Tradition says that he was bishop of Benevento, where he was seized during the persecution of Diocletian and carried to Nola. After being tortured, he was taken to Pozzuoli and put into prison, whence he was forced into a den of lions, by whom being left unhurt his persecutors caused him to be beheaded. His body was carried to Benevento, but removed to Naples by Alexander VI. in 1497. It is still preserved in the crypt of the cathedral in that city, and in a chapel of the same church are also kept the head of the martyr and two phials supposed to contain his blood. Many miracles have been ascribed to the relics: the principal one was the famous liquefaction of the blood annually on the 19th September, the day of the martyrdom, a priestly juggle, which has lately been very fully exposed.

JANUARY, the first month in our present Calendar, was also the first month in the Roman Calendar. It was not the first month in the year in this country till 1752, when the legislature, by an act passed in the preceding year, altered the mode of reckoning time from the Julian to the Gregorian style. At that time it was directed that the legal year, which began in some parts of England on 1st March, and in others on 1st January, should universally be deemed to begin on 1st January. [PERIODS OF REVOLUTION.]

JANUS, in mythological history, is the earliest of the Italian kings, and reigned in Latium, being contemporary with Saturn. Janus, by some accounts, was the son of the sun, and his attributes appear to connect him with sun-worship. He is the porter of heaven; he opens the year, the first month being named after him; he presides over the seasons, whence he is sometimes represented with four heads (Janus Quadrifrons), and his temples in that capa-

city were built with four equal sides, but only one entrance. He is the keeper of earth, sea, and sky; the guardian deity of gates, on which account he is commonly represented with two heads, because every door looks two ways; and thus he, the heavenly porter, can watch the east and west at once without turning. He usually carries a key in his left hand, and a staff in the other. In war times the gates of the principal temple at Rome, that of Janus Quirinus, were always open; in peace they were closed to retain the wars within; but they were shut once only between the reign of Numa and that of Augustus.

JAPAN, EMPIRE OF. A collective name given to an archipelago of islands in the North Pacific Ocean, off the coast of China, consisting of three large mountainous and volcanic islands, Nippon, Kiusiu, and Sikok, and an immense number of smaller ones, among which may be enumerated Sado, Tsousima, Awadsi, Tanegasima, Yki, Yaksima, and Oosima, with the groups Okisima, Gotusima, and Kosikisima. These form Japan Proper. The large and fertile island of Yesso, north of Nippon, and separated from it by the Strait of Sangar or Matsmai, with the southern half of the island of Tarakai, Krafto, or Saghabin, and the larger and more southern of the Kurile group, are included in a dependency, called the province of Matsmai. Taking Japan to include also the dependency of the Loo Choo Islands, it extends from lat. $24^{\circ} 16'$ to 50° N., and long. 128° to 151° E., or covering an area of about 1830 miles by 1800. N. spreads the Sea of Okhotsk, E. and S. the vast expanse of the Pacific Ocean, W. and N.W. the Strait of Corea, the Japanese Sea, and the Gulf of Tartary. The following table sets forth the number of islands which comprise this remarkable and extensive empire:—

Principal Islands.	No. of small detached isles.	Area in geog. sq. miles.
JAPAN PROPER:—		
Nippon, ...	1,269	} ... 87,304
Kiusiu, ...	1,515	
Sikok, ...	526	
Yki, ...	201	
Tsousima, }		
DEPENDENCIES:—		
Yesso, ...	83	20,723
The Kuriles, ...	48	1,412
Saghabin, ...	27	11,194
Boninsima group, ...	89	92
Loo Choo Islands, ...	92	2,010
	3,851	122,735

The population of the empire is variously estimated at from 15,000,000 to 60,000,000. But we know as yet too little of Japan to be able to base our computations on any satisfactory data. Commercial enterprise, however, is the handmaid of geography, and by the labours of our merchants and traders we may reasonably hope in due time to penetrate the mists and shadows which a singularly jealous government has drawn around this mysterious portion of the civilized world.

Physical Aspect, &c.—The largest island, Nippon, or Nippon, whose name has been corrupted into Japan, and is said to signify in Chinese 'Sunborn,'

or 'Land of the Rising Sun,' has a crescent shape, with the curved side turned towards the Asiatic continent. It measures 800 miles from N.E. to S.W., while its breadth varies from 50 miles to 100. Kiusiu, divided from Nippon by a narrow channel, is about 200 miles long from N. to S., and 120 miles broad. Sikok, which lies to the E. of Kiusiu, is 140 miles long by 60 miles broad. The straits to the N. and E. which divide Sikok from Nippon are about 12 miles broad, but so beset with isles and islets that the navigable channel is frequently not more than one mile wide. Yesso is of a triangular form, and its three sides are respectively 300 miles, 260 miles, and 220 miles in length. The Strait of Sangar, about 8 miles wide, separates it from Nippon on the S.E. To the W. lies Sado, between Cape Noto and Russian's Cape: it is supposed to be about 45 miles long and 21 miles to 24 miles broad. The narrowest part of the channel which divides it from Nippon does not exceed 20 miles across.

The coasts are generally rocky, and extremely irregular, being broken up with numerous romantic inlets. They are deficient in good harbours, and from this exposure to frequent typhoons are the scene of numerous shipwrecks. A mountainous chain of considerable elevation traverses the whole insular series in the line of its greatest extent, many of its higher summits remaining clothed in snow for several months, and some throughout the year. In Nippon the highest peak is Fusi, a dormant volcano, 12,000 feet high; but generally the range is sufficiently low to admit of cultivation up to the sources of the waters.

The Japanese islands form a link in that great chain of volcanic action which is carried on from Kamtchatka through the Philippines, Sumbawa, and Java, to Sumatra, and thence, in a north-westerly direction, to the Bay of Bengal. The igneous agency is especially conspicuous in Yesso, Nippon, and Kiusiu, and earthquakes are of common occurrence in all the islands. In Yesso occurs the great volcanic mountain of Fusi-yama, dormant since the year 1707, and rising to the elevation of 14,177 feet above the sea, so as to form the culminating point of the whole empire. It is the *mons excelsus et singularis* (the lofty and singular mountain) of the old traveller Kämpfer, who visited the island in the seventeenth century as physician to a Dutch embassy. 'Poets cannot find words,' he says, 'nor painters skill and colours, sufficient to represent the mountain as they think it deserves.' It forms a magnificent cone, with an extensive truncated pinnacle, and shooting heavenward above all the encircling hills, its snowy crest is visible from Yeddo, a distance of 80 miles. Fusi-yama, the 'Rich Scholar's Peak,' is regarded by the common people as a 'holy place.' They make pilgrimages to it, as the Moslems to Mecca, to ward off the anger of the gods, dressing for the occasion in white vestments, which the priests inhabiting the summit (during the summer months) stamp with various mystic seals and devices. A tradition runs that the volcano rose in a single night from the bowels of the earth, and that a spacious lake was simultaneously formed at Miaw, evidently referring to some great volcanic convulsion.

Several terrible eruptions have occurred in Yesso;

one, in 1783, destroyed twenty-three populous villages; while the volcano of Wauzendake, in Kiusiu, broke forth in 1792, and overwhelmed with floods of lava and torrents of ashes and scorice no less than 53,000 people.

The Japanese mountains present no bare and rugged outlines, being cultivated to their summits, or mantled with shaggy woods. The soil, in volcanic districts, is a rich, black, stoneless mould, several feet in depth, and composed of the detritus of igneous rocks; it has been enriched for several centuries by a constant application of the sewage from the great towns. The principal formations of the islands are trachyte and basalt; hills of sandstone are numerous; and plastic clay, marl, and felspar abound in various localities. The metallic treasures of the empire are considerable, comprising

gold, silver, tin, copper, lead, and iron; both the tin and copper being of superior quality. Coal-measures are found in various districts; sulphur occurs in large quantities; and ambergris is found on the shores. The sulphur is admirably pure, and inexhaustible supplies are procurable at Sulphur Island, an active volcano, off the S. coast of Kiusiu. Hot mineral springs, saline and sulphureous, are largely patronized by the Japanese. The small village of Atami, sequestered in a seaward valley on the S.E. coast of Nippon, possesses so many boiling fountains that the entire locality may well be compared to a gigantic witches' cauldron. From numerous apertures is ejected a vast volume of steam and slightly sulphurous water at a temperature of from 100° to 120° Fahr.

Climate.—In the northern islands the winters

Fusi-yama, from the Suburbs of Yeddo.

are long and severe; the summers short, but intensely hot. Snow lies even in the plains and valleys from November to May. In the southern regions of the empire the climate is not unlike that of France, the extreme heat of the summer months being tempered by the influence of the ocean breezes. The weather is more boisterous, and the general climate colder, on the western than on the eastern coast, for the same reason. In Kiusiu, and the S. of Nippon, the range of the thermometer extends from 29° to 104° , 80° being the summer average, and 35° that of winter. In June, July, and August the rains descend with great violence, dense fogs occur, and typhoons of fearful violence strew the shores with wrecks, and cover the interior with desolation. In lat. 32° N. ice is formed of nearly an inch in thickness, and in lat. 4° obtains such consistency that the rivers may safely be crossed by the pedestrian. Southerly winds are prevalent during the months from March to September, blowing almost with the constancy of a monsoon, as well over the open ocean as over the more secluded waters of the Japanese Sea and the Gulf of Tartary.

Vegetation.—From the semi-tropical, semi-temperate character of its climate, Japan possesses a singularly rich and varied flora. In the N. flourish vast forests of oak and pine; in the S. the sago palm, the tree-fern, the banana, the bamboo, bigonia, and myrtle delight the eye with their graces of form and wealth of colour. The landscapes are also diversified by rich clusters of hydrangeas, camellias, japonicas, and azaleas, which here attain a luxuriance and a beauty unknown in Europe. Amongst the trees which hang their glories on the mountain sides are the chestnut, maple, beech, elm, lime, elder, and

cypress. Japan also possesses a peculiar cedar (*Cryptomeria Japonica*), which borders the high roads with stately avenues, and frequently springs to an altitude of 130 feet. Their upper branches, uniting from either side, constitute a perfect canopy of leafiness. The orange, pomegranate, pear, apricot, and peach, though now common in Japan, and of great excellence, with many other fruits and garden plants are of foreign extraction, and were probably introduced from Corea and China. The camphor tree (*Laurus camphora*), found in most of the forests, occasionally attains to huge dimensions. One, visited by Kämpfer, in the island of Kiusiu, is still standing, and supposed to be upwards of 1000 years old. The lacquer or varnish tree (*Rhus vernificera*) furnishes the gum with which the Japanese heighten the brilliancy of their *papier maché* articles. Hence arose the term *japanning*. The wax-tree (*Rhus succedanea*) yields seeds from which wax for candles is obtained by compression. It thrives best on barren and stony ground, ripens in its eighteenth year, and afterwards declines. Another valuable tree is the paper-mulberry (*Broussonetia papyrifera*), whose bark supplies the paper of which the Japanese make such extensive use. In the south the sugar-cane is successfully cultivated. Rice yields two crops annually, and is the staple food of the majority of the population. Tea of a superior quality is largely grown, and cotton, tobacco, ginger, melons, buckwheat, pumpkins, and cucumbers are also objects of culture; for the industry of the Japanese, like the persevering ingenuity of the Chinese, compels the most ungrateful soil to yield a liberal return.

Zoology.—The bear is said to haunt the woods of Yesso, and in the north of Nippon linger a few wolves

and boars: these, with foxes and hyænas, are the only wild animals that Japan possesses. Those of a tamer class are not very numerous, owing to the great extent of ground occupied by the agriculturist; but some species are protected by the laws, and others by the partial abstinence of the inhabitants from animal food. The stork is as sacred in Japan as in Holland. Deer run freely about the public streets. Buffaloes and zebu abound, but are only employed for draught and burthen. Among the domesticated quadrupeds are horses, sheep, dogs, pigs, and cats. Birds are numerous, and include geese, ducks, teal, pheasants, ravens, larks, pigeons, and pelicans. Snakes are commonly met with, and one species, the *ourabami*, grows to an enormous size. There are also tortoises and lizards, scorpions, centipedes, and other genera of the insect world. The seas and rivers teem with wholesome fish, which form an important article of food both with the upper and lower classes.

Manners and Customs, System of Government, &c.

—We possess as yet no very full or accurate information respecting the Japanese system of government. The nominal head of the state is a spiritual emperor called the *Mikado*, who keeps himself secluded from the vulgar gaze, and, like the Lama of Tibet, is considered of semi-divine origin. Of equal influence and authority is the temporal emperor, the 'Ziogun,' or, as commonly called, the Tycoon, whose office is hereditary, and who represents the central executive power. Yet neither the mikado nor the tycoon appear to engross the whole authority, and the actual government seems vested in a number of feudal and almost independent princes, or 'daimios,' lords in their own right of a more or less extensive territory, over which they exercise an uncontrolled supremacy. Not only, as recent events have shown, are these independent of the central authority, but they even claim the right of removing the tycoon and his ministers. A recent writer, however, asserts that the Mikado has no spiritual character, and that the relation which exists between him and the Tycoon is analogous to that held of old, by the incompetent Merovingian kings of France, and their potent 'Mayors of the Palace.'

The administration of the empire is conducted by two councils of state; the first, called the 'Gorgio,' composed of five members, and the second, or 'Omva-kadouchisri,' of seven members. Over the first council, which may be taken to represent the executive authority, presides the 'gotario,' or chief minister, who, in the minority or during the illness of the tycoon, acts as regent. The 'gotario' is elected by the two councils of state and the principal daimios, from among the latter.

The daimios, according to Sir Rutherford Alcock, are divided into two classes; the first, including those whose annual revenues exceed 7000*l.*, while the 'saimios,' or second class, possess yearly incomes beneath that amount. Each of the first-class magnates is lord within his own territory, like the feudal baron of mediæval Europe, and has power of life and death over all his subjects and vassals. Certain districts only are under the immediate control of the central executive, and their revenues are assigned as a civil list to the mikado and tycoon. As already hinted, the real governing power is in the hands of the

daimios, among whom the greater portion of the land is divided, and who receive seven-tenths of the annual produce of rice. Each daimio must reside six months in the year at Yeddo, and during their absence from that city, their wives and families are held as hostages. They maintain a large number of retainers or dependents; one daimio possessing as many as 40,000, who are as ferocious and lawless as the bodyguard of a mediæval baron. The laws of the empire are most sanguinary in principle, and appear to have been written in blood; but practically they are modified and ameliorated by the discretion of the local magistrates. The most remarkable punishment is that of the 'happy despatch,' or *haru-wo-kiru*, in which the offender becomes his own executioner, by making two cross-cuts on the abdomen with a sword or sharp-pointed knife. Almost all crimes are legally punishable by death; the universal panacea which, in Japan, cures every moral disease. Reformatories are unknown; the improvement of evil-doers is never deemed possible; and the short cut of the headsman's sword severs those Gordian knots of social economy and internal policy which in Europe still puzzle philanthropists and statesmen.

The Japanese are among the most ingenious, industrious, and peaceable people in the world, and their artisans are distinguished by their fertile fancy and exquisite skill. They are excellent workers in metal; there is no piece of foreign machinery which they cannot reduplicate and imitate; their sword-blades are more finely tempered than those of Birmingham or Sheffield; they are equally distinguished as silk-manufacturers and landscape gardeners; adepts in jewellery or in Bramah locks; good builders and road makers, agriculturists and carpenters. In physiognomy they correspond to the Mongolian races, and are probably sprung from them, with an admixture of Malay blood. Their eyes are small, dark, and twinkling; their eye-brows heavy and arched; their complexion varies from a light olive hue to a deep copper; in limbs they are robust and muscular; in stature below the ordinary standard. The men elaborately embroider their persons with tattooed devices of dragons, lions, tigers, and fantastic imaginary objects. They wear a robe of cotton, gauze, or silk, according to their means; it falls down from the neck to the ankles, but is gathered in at the waist with a girdle; the colour is black or dark blue. The women dress more gaily, and plaster themselves with paint and powder; they varnish the teeth with black, dye the lips a brick-red, pluck out every hair from the eyebrows, and cover the face and neck with rice-flour.

John Japan, says a lively writer, is altogether a contradictory and anomalous sort of individual. He is a gentleman with oblique eyes, shaven crown, and yellowish complexion, who arrays himself in gown-like garments, with a fan in his girdle, straw slippers on his feet, and a bamboo hat, half sombrero, half parasol, on his head. When travelling, he carries a cloak made of oiled paper to protect him from the rain, or a straw cape which hangs from the shoulders like the thatch on a stack. He scrambles up his horse, not on one side, but by the animal's breast, and accomplishes his journey on a saddle of wood, or on a little platform, where he sits cross-legged, like a

tailor at his table. His pocket-handkerchiefs are made of paper, there being two sorts in vogue for this purpose—namely, common nose-paper and large nose-paper. He eats various sorts of animal food, from venison to whale, or even a slice of shark; and he is still more catholic in regard to vegetables, for he will luxuriate over a mess of boiled sea-weed. He divides his day into twelve hours, of which six are given to sunshine, and he illuminates the darkness with candles, hollow in the centre, and wicks made of paper. He buys his wife, and marries her in a shroud; permits her to smoke, and to bathe in public. He blisters himself once every six months, whether he is well or ill, and with burning wormwood leaves. And when he shuffles off this mortal coil, he is placed in a sitting posture in a round cup-like coffin, interred in a grave shaped like a well, and mourned by his kinsmen in the whitest of white garments.

Let us walk into a Japanese house, which by law must not be more than 44 feet high, passing without notice the worthy householder who sits in a tub of water at the door, performing his ablutions with a refreshing freedom from bashfulness. You will notice that the floor is slightly raised above the level of the earth, and thickly covered with mats of rushes and rice-straw, elegantly decorated. These mats are used instead of chairs, and there are no tables; but when you take refreshment, you will be provided with a little raised tray. There are no beds; you must sleep upon mats, sit upon mats, smoke upon mats, and fidget upon mats.

Observe that the rooms—which are all on one story—are separated by folding-screens of gilt or coloured papers, and lighted by windows of oiled paper, for glass is unknown. You cannot warm yourself at the fire, for the Japanese build no fire-places; but in the middle of the room you may crouch down on the brink of the square-tiled hole, from which ascend the fumes of charcoal. The said charcoal, we may add, is always burning, and over it a pot of water is always boiling. The Japanese drink tea voraciously; they use little sugar, and serve it up in dainty porcelain cups.

The bath-room resembles European bath-rooms in its general appointments; but it is more frequently resorted to than in our chilly British isles. The men bathe, the women bathe, the children bathe, in-doors and out-of-doors, morning, noon, and night.

Every street in a Japanese town is controlled by its own official, the *Otona*, who is a combination of authorities, being police-inspector, magistrate, registrar, and consul. The citizen cannot remove from one street to another without a certificate of good behaviour from the *otona* under whose government he has been living.

Rendall, in his 'Memorials of the Empire of Japan,' pronounces an opinion on the Japanese character, which seems both impartial and accurate: 'They carry their notions of honour,' he says, 'to the verge of fanaticism, but they are haughty, vindictive, and licentious. On the other hand, brawlers, braggarts, and backbiters are held in the most supreme contempt. The slightest infraction of truth is punished with severity; they are open-hearted, hospitable, and, as friends, faithful to death. It is represented that there is no peril a Japanese will not encounter to serve a friend; that no torture will

compel him to betray a trust; and that even the stranger who seeks aid will be protected to the last drop of blood.'

Religion.—There are several religious orders, hermits, and holy men who give themselves up to a life of prayer and solitude for the mortification of the flesh; and others, like itinerant monks, wander about in a state of mendicancy, dealing in charms and incantations for the cure of disease, the recovery of criminals, &c. Sir Rutherford Alcock states that two sects of the blind exist, founded by two great celebrities in Japanese history; one, by the third son of a mikado, who wept himself blind on the death of his mistress; and the other, by a defeated general in the civil wars, who tore his eyes out that he might not be provoked to take the life of a generous victor. Into these two sects, half-religious, half-secular, persons of all ranks enter. They are generally, but not exclusively, musicians, and maintain themselves by playing on musical instruments.

Engrafted on the Sinto, or ancient religion of the Japanese, which was non-idolatrous, are the two derived from China—Confucianism, Chinese in origin; and Buddhism, which has been imported from India. The former was adopted in the first century of our era, the latter not until the sixth. The Japanese writers assert that the somewhat arid doctrines of Confucius made but slow progress, whereas Buddhism rapidly found votaries, and the most effectual and persuasive arguments were those which spoke of the immortality of the soul and the promises of a future life.

Many of the Japanese temples are of great extent and magnificence. One of the largest and most celebrated in Yeddo is the temple of Asava, situated in one of the most populous quarters of the city. It is also called the temple of Quanonas, the god Quanon of thirty-six arms and a hundred hands, who must be very popular, says Alcock, to judge by the crowding of the thousand idlers, who seem to be never wanting in its vicinity; and who rush through from one extremity to the other to catch a sight of the foreigner, with an uproar as loud as distant thunder. A long avenue intervenes between the outer and inner gateway, and on each side of it are placed stalls or booths forming a vast bazaar of a very mixed character. 'Toys for children occupy a large space; a few little stone models of shrines, idols, tombstones, and temples were the only things I could perceive having the remotest connection with the ascribed sanctity of the edifice adjoining. Trinkets for women—especially metal pins for their hair, and combs, almost the only article they appear to indulge in; and, perhaps, to make up for any restricted use elsewhere, they sometimes carry a forest of these on their heads; pins with hollow glass heads, filled with bright coloured liquids, also seemed to enjoy great favour. The infant windmill, stuffed tigers, and barking dogs, drums and fifes, and miniature swords, bows and arrows, dressed dolls, and masks, kites, and even hoops, seemed to make the staple of the toy booths; so that our common humanity asserts itself even in toys for Japanese children. Of course picture-books and gaudy prints were not wanting; nowhere in Japan apparently, certainly not in Yeddo, is the supply of these deficient.'

In every temple you observe the same stereotyped

features—an altar, an image, chandeliers, paintings, and trumpety decorations of artificial flowers. The same 'bell and book,' priests in their robes and scapulars, acolytes in attendance, and choristers to stand behind the officiating bonze; the same burning of incense; the same reiteration and mumbling of prayers and rituals in an unknown tongue, unknown even to the priest who gabbles them; at other times consisting of three words, incessantly reiterated for an hour without ceasing, 'Amida! Amida! Amida!' the name of the god.

The religious duties of the Japanese consist chiefly in worship at the temples, where they display a very reverent behaviour, and the observance of festivals, pilgrimages, periodical adoration of tutelary divinities, reverence to parents, obedience to magistrates, and offerings at the tombs of their ancestors. For strange as it may appear, considering the general indifference of the Japanese to death, they manifest a peculiar regard for the dead, and the solid and elaborately carved granite monuments in a Japanese cemetery are admirable specimens of architectural taste and skill. Each body is buried in a sitting posture, with the hands folded as if in prayer, and all the coffins are circular in shape.

Principal Cities.—Jeddo, or Yeddo. [JEDDO.]

Miako, an inland city, upwards of 200 miles to the westward, is the ancient and still the titular

capital, as well as the residence of the mikado. It is said to contain 500,000 inhabitants. Its temples are innumerable; its houses of a better class than those of Yeddo, and enriched with blooming gardens. It is the educational centre of the Buddhist priesthood, and has considerable manufactures of carved ornaments and japanned wares.

Osaka, a few miles to the S.W., is one of the ports opened to European commerce by recent treaties. It is a busy and populous commercial centre, on the banks of a navigable river, which is spanned by more than a hundred bridges. Its port, Hiogo, stands on an arm of the Savrada Sea, and possesses several docks and shipbuilding yards. (See Plate.) Osaka is also a fashionable resort of the Japanese nobility, who delight in its splendid theatres, brilliant gardens, and luxurious tea-houses.

The Dutch traders have held commercial relations with the port of *Nangasaki* for upwards of two centuries. It occupies the shore of a large bay, inclosed by pine-clad hills, on the western side of the island of Kiusiu, upwards of 800 miles from Yeddo, and about ten days' steam voyage from Hong Kong. Its manufactures are important, and its foreign trade has attained to considerable dimensions. The climate is very genial. There is scarcely any winter, and in summer the temperature ranges from 60° to 80°.

View of Nangasaki Harbour.

Matsmai, the chief town of Yesso, situated at its southern extremity, contains, it is said, 50,000 inhabitants, and is controlled by a feudatory noble.

Hakodadi, a treaty port on the N.E. of Matsmai, 650 miles from Yeddo, is small and of recent origin, but already growing in commercial importance. In position as well as in aspect it resembles Gibraltar. The winters are extremely cold; the thermometer has been observed to register 18° below zero; the snow lies on the plains till the close of April, and

storms of rain, driven up by the S.E. winds from the Pacific, herald the return of spring. (See Plate.)

History.—The early annals of Japan are shrouded in mysterious obscurity. The empire was unknown to Europeans until discovered by the Portuguese about the year 1452. Christianity was then introduced by the Jesuit missionaries, under the auspices of the famous St. Francis Xavier, but owing to their interference with state affairs, the enterprise termi-

nated in a most tragical catastrophe. A persecution followed of forty years' duration, and was only ended by a sanguinary massacre which left not one Christian alive in the empire.

In 1611, the Dutch contrived to obtain permission to establish a factory at Firands. They were then at war with Spain, and Portugal was at that time under Spanish government; and the Hollanders, by their intrigues, soon contrived to oust the Portuguese from the empire, and monopolize the whole of its foreign commerce. In the reign of Elizabeth, an English mariner, named William Adams, being wrecked on the coast of Japan, was detained a prisoner for life, but obtained such influence over the Tycoon, that he succeeded in opening up a commercial intercourse between Japan and England. For several years the English flag was constantly seen in the Japanese ports, but during the reign of James I. it was withdrawn, and the Japanese ports rigorously closed against all vessels but the Dutch.

European traders remained thus excluded from the commerce of Japan until 1854, when it was thrown open to the great Western Powers by a treaty enforced by the American squadron, under Commodore Perry. At a solemn assembly of the principal state officials, held at Yeddo, in June, 1856, it was decided that the two imperial ports of Nangasaki and Hakodadi should be free to the vessels of all nations for commercial purposes, to refit, reprovise, and establish depôts of coal. To vessels in distress it was agreed that any port should be accessible, on condition that they put to sea immediately the peril was over. But no foreigner was to be allowed to penetrate into the interior without a special license. In 1858 the Americans negotiated a treaty on a much more favourable basis, inasmuch as it provided for a resident minister at the court of Yeddo, and for the opening of the ports of Kanagawa, Nangasaki, and Hakodadi, while the two principal cities, Yeddo and Osaka, were also released from the oblivion of centuries. In the

summer of the same year, the earl of Elgin, on the part of Great Britain, and Baron Gros, on behalf of France, having successfully concluded a mission to the Chinese court, proceeded to Japan, with a powerful fleet, and negotiated a treaty which conferred on European powers the privileges previously conceded to the United States. It was signed in due form at Yeddo, on the 26th of August, 1858. Diplomatic agents were to reside at Yeddo and London, with the privilege of travelling freely to any part of the empire; the three ports already named were opened up to British and French traders, with permission to establish permanent factories and have ground for building. They were also allowed to move unchecked to any point within 30 miles of their place of residence. Cotton and woollen fabrics were to pay a duty of only five per cent. of the declared value on importation. On almost all other articles a duty of twenty per cent. was imposed, and it was agreed that after the 1st of July, 1862, the tariff should be subjected to a general revision.

Though Japan was thus admitted within the potent influences of European civilization, the intercourse between the Western nations and this jealous empire of the East has not flowed freely. Serious differences have arisen owing to the persistent efforts made by the Japanese to render the treaty stipulations inoperative, and the murder of some British subjects by retainers in the service of Prince Satsuma, a powerful and arrogant daimio, led to the bombardment and destruction of his palace, town, and fortifications by a British squadron, under Admiral Kuper. Since that event, and owing in no small measure to the firmness and sagacity of our late representative, Sir Rutherford Alcock, our relations with the Japanese have assumed a more satisfactory character, and a steady increase has taken place in British commerce. Kanagawa is at present the principal trading port.

The commercial intercourse of Japan with the United Kingdom is shown in the subjoined tables :—

In addition to the above, the imports of foreign and colonial produce and manufactures from Great Britain into Japan were valued in 1864 at 39,609*l*, making the total amount 666,992*l*.

(*History of Japan*, Kæmpfer; Rendall's *Memorials of Japan in the sixteenth and seventeenth centuries*; Commodore Perry's *Narrative of the American Expedition*; Sir Rutherford Alcock, *Capital of the Tycoon*; Sherard Osborne, *A Cruise in Japanese Waters*; Oliphant's *Narrative of Earl of Elgin's Mission*; Siebold's *Japan*; Martin, *Statesman's Year Book*; Blue Books presented to Parliament; *Revue des Deux Mondes*, 1865; *British Quarterly Review*, &c., &c.)

JAPANNING is the art of producing a highly varnished surface on wood, metal, or other hard substance, sometimes of one colour only, but more commonly figured and ornamented. The process has received its name from that of the island of Japan, whence articles so varnished were first brought to Europe; though the manufacture is also extensively practised by the Chinese, Siamese, Birmanese, and other nations of eastern Asia, among whom it was suggested most probably by the possession of a tree, which affords with little preparation a beautiful varnish, exceedingly well adapted for the purpose, and which hardens better than those prepared in Europe. [VARNISH TREE.]

The appearance of japanned work is as various as the taste and fancy of the artists employed upon it. Sometimes it is a plain black or red, with a gilded or painted border; or it is an imitation of marble, of fine grained or rare wood, or of tortoise-shell; sometimes a drawing, with high finish, brilliant colour, and showy patterns; and occasionally fine copperplate engravings are applied to a japanned surface with good effect. In all cases the work is highly polished and varnished.

Japanning is applied to ladies' work-boxes, and work-tables, to toilet-boxes, cabinets, tea-caddies, fire-screens, tea-trays, bread-baskets, snuffers and trays, candlesticks, and a variety of other articles.

The japanning material consists of anime, or copal varnish, mixed with different substances, according to the intended colour of the ground. After being varnished with this mixture the articles are heated in an oven till perfectly dry. In the better class of goods the process is repeated several times to insure a good ground. When thoroughly dry, after the last application, they are painted or gilded as required, after which nothing remains but the finishing. This is a very simple process: the workman chooses a suitable varnish, and passes it over the work with a brush several times, until he judges the coating to be thick enough to bear the polish. It is an important precaution not to begin the varnishing until the preceding work is thoroughly dry, and to dry perfectly each coat before laying on a succeeding one. A hot stove is used in the best establishments to aid in drying the work. When thick enough, the varnish is polished by rubbing it with a rag dipped in finely powdered tripoli or rottenstone. Towards the end of the operation a little oil is also applied to the rag; and the work is completed by rubbing with oil alone, to clear off the powder or any other impurity. In the manufacture of papier mâché the process is very similar to japanning. Lacquering is also done in the same way, but this word is more generally applied to metal articles. In 1864 the imports of japanned or lacquered ware amounted to 408 cwts., valued at 6620*l*. In the same year 235 cwts., value 9118*l*., were exported.

JARASLOV. [YARASLOV.]

JARNAC. [CHARENTE.]

JASHER, BOOK OF, or the 'Book of the Upright,' is twice referred to in the Old Testament as a work of authority. (Josh. x. 13; 2 Sam. i. 18.) Many conjectures have been formed concerning the author and contents of this book; but the work appears to have been lost before the time of the Babylonish captivity. In the year 1751 a pretended translation was published by a printer of the name of Ilive. In 1855 Dr. J. W. Donaldson published a work in which he endeavoured to prove that

none of the books of the Old Testament were written before the time of Solomon, and then only as fragments, which he thinks formed the Book of Jasher, and that these fragments were afterwards worked up into the shape of the existing books, at least as far as the Psalms. This theory was combated by the Rev. J. J. S. Perowne and others, and it has met with but little support either in Germany or England.

JASIONE, a genus of plants belonging to the natural order *Campanulaceæ*. There is only one British species of this genus.

JASMINACEÆ, a natural order of monopetalous Exogens. Only four genera of this order have yet been discovered, the principal being *Jasminum* itself, which consists of a large number of species, found in Europe, Africa, Asia, and Australia.

JASON. [ARGONAUTS.]

JASSA, a genus of amphipodous Crustaceans, established by Dr. Leach.

The general characters resemble those of *Corophium* (Latreille), but differ from them as well as from those of *Podocerus* (Leach), in the considerable size of the hands of the first four feet, which are oval; those of the second pair being the greatest, and armed with teeth more or less numerous on the internal border. Eyes not projecting.

Dr. Leach records two species: one, *Jassa pulchella*, from the south coast of Cornwall, where it was found in the midst of sea-weed; the other, *Jassa pelagica*, found near the Bell Rock, Scotland.

JASSEY, or **YASSY**. [MOLDAVIA.]

JATROPHA, a genus of plants, containing among its numerous species the *Jatropha manihot*, a Brazilian and Guiana plant, the fecula of which forms a well-known nutritious substance called *Cassava*, when prepared in one manner, and *Tapioca* in another state.

JAUNDICE (from *Jaune*, 'yellow') is the name given to those diseases in which the excretion of the bile being prevented, it is retained in the blood, or reabsorbed, and being diffused throughout the system, gives a yellow colour to the skin, and all the other tissues and secretions.

Everything which obstructs the main trunk of the bile-ducts, as gall-stones or other foreign bodies filling its canal, morbid alterations of the liver or duodenum, or of the duct itself, tumours and enlargements of adjacent organs, and inflammation of the liver, will produce jaundice. But the most frequent cases are those which do not appear to be the consequence of any organic disease, but are accompanied by the symptoms of general disorder of the digestive organs, as nausea or vomiting, thirst and loss of appetite, confined or irregular condition of the bowels, headache, and general uneasiness.

It is impossible that any one mode of treatment should be adopted for a symptom depending on such varied causes. Where the obstruction is mechanical, the jaundice is of course curable only by the removal of its evident cause; and in inflammation of the liver it is but a symptom of a more important disease, to which the treatment must be directed. In the more common cases, which, as distinguished from these, are sometimes called functional, the treatment should consist chiefly of small doses of mercury, and active purgatives, containing calomel or neutral salts.

JAVA, one of the Greater Sunda Islands, belonging to Holland, is situated between $5^{\circ} 52'$ and $8^{\circ} 46'$ S. lat., and between $105^{\circ} 11'$ and $114^{\circ} 13'$ E. long. The length is 628 miles; the breadth varies from 40 to 130 miles. The area is estimated at 50,000 square miles. The population is given at 9,943,075, having doubled itself in thirty years.

The shores are washed by the Indian Ocean, the Java Sea, the Straits of Sunda, and the Straits of Bali. The island of Madura, almost close to Java, is 91 miles long, and 31 miles wide in the widest part.

Surface and Soil.—The southern coast in its whole extent is high and steep. It runs in a continuous line, with few indentations, and those not deep. Consequently there are few places which have good anchorage.

The hilly country which is contiguous to the southern coast rises rapidly as we advance inland, and attains towards the middle of the island a mean elevation of more than 1000 feet, where it extends in elevated plains with an uneven or hilly surface. Several ridges traverse this elevated region, having numerous volcanic peaks, some of which attain an elevation of from 10,000 to 12,000 feet. The hilly district contains also some extensive plains and fertile valleys, inclosed by the peaked ridges. This elevated area terminates to the north in rather a steep slope, and between it and the Java sea extends a flat country, which descends imperceptibly from the foot of the hills to the very shores, where it is frequently covered with swamps.

The northern coast is lined by numerous small islands, and marked by many projecting points and headlands. Accordingly the harbours are numerous; and the adjacent seas are navigated by numerous vessels of small tonnage.

The soil of Java is generally deep and rich. The best soils are alluvial, along the beds of the rivers, but the fertility of the whole island is far above the average. Java is watered by numerous rivers, but few of them have a considerable course on account of the comparative narrowness of the island. Five or six are navigable at all times to a distance of some miles from the coast. The rest, in number many hundreds, are used to irrigate the fields. The chief rivers are the Solo and the Kediri, or Surabaya. There are swamps, but no lakes.

In Java, as in other countries between the tropics, the year is divided into a wet and a dry season, and these seasons depend on the periodical winds. Hurricanes are very rare, but thunderstorms are frequent and destructive, and earthquakes are common in the vicinity of the volcanoes.

Though not equal to the Hindus in agriculture, the Javanese are far superior to their immediate neighbours of the other islands. They are well acquainted with the cultivation of rice and other grains, and with the advantages of irrigation. Wheat was introduced by the Dutch, and is cultivated on the more elevated lands. Millet is grown in some places on a limited scale. Among the many esculent roots cultivated, the principal are the yam, the sweet potato, the Java potato, arrow-root, the common potato, artichokes, cabbages, and peas. The Javanese also cultivate cucumbers, onions, capsicums, coconuts, ground-nuts, areca palm, betel, tobacco, coffee, sugar, pepper, cardamoms, ginger, cotton, and great

varieties of dye-stuffs, and fruits. They procure oil from many of their trees, and make toddy from the palm.

Java is the granary of the Asiatic Archipelago, and is supposed to be capable of supporting many times its present population—only about one-third of the surface being yet under culture; its temperature, hot in the plains (ranging from 85° to 94° Fahr.), is cooler in the elevated parts, and the highest peaks are often covered with ice. The climate, except in the marshy regions of the north, is healthy.

There are no elephants, camels, or asses. The horses are of a small breed, but strong, fleet, and well made. Buffaloes are numerous, and of greater use in agriculture than any other animal. Black cattle and goats are common, but sheep and hogs scarce. There are tigers, tiger cats, leopards, jackals, rhinoceroses, and other wild animals, and also crocodiles and serpents. Domestic fowl and fish are very abundant.

Political Divisions, Towns, &c.—The government is administered by a governor-general (who has authority over all the Dutch East Indian colonies), assisted by a secretary-general, and a council of four members, of Dutch descent. Three superior tribunals and courts-martial are seated at Batavia, Samarang, and Surabaya, the whole being subordinate to a supreme court at Batavia. There is complete religious toleration, and Europeans are not prevented from going to Java, though the permission of the governor-general is necessary to their settling there.

Java is divided into twenty-two residences, in each of which are a European governor and secretary, and various sub-residents. These provinces are subdivided into arrondissements and communes, in each of which is a justice of the peace. The most considerable and remarkable towns in the country are on or near the northern shores. *Batavia* is the capital. [BATAVIA.] *Cheribon* is a thriving town, with a good roadstead and 11,000 inhabitants. It is the residence of a Dutch governor, and has a trade in coffee, indigo, teakwood, &c. Population of residency, 550,000. Among the inland towns is *Buitenzorg*, a thriving and well-built town, thirty-five miles from Batavia; it is united to the harbour by a navigable canal; has government buildings, and the hotel of the governor-general. *Samarang*, a fortified seaport on the northern coast, the capital of a province, near the mouth of the river of the same name, 210 miles E.S.E. Batavia. The population numbers 22,000, including many Chinese. The harbour is not good, and the town is unhealthy from contiguous morasses. Coffee, pepper, and rice are produced in the adjacent country. It is the residence of the Dutch governor, and the seat of one of the three principal law-courts in Java. Population of residency, 550,000. *Surabaya*, or *Sourabaya*, has an excellent harbour, a flourishing trade, and 130,000 inhabitants. It is situated in lat. 7° 12' S., long. 112° 44' E., has a government house, a mint, and large store-houses. The harbour is defended by many forts and batteries, and is the best in Java; there are also shipbuilding docks, an extensive iron floating dock, capable of containing ships of the greatest burthen, a naval arsenal, and a cannon foundry.

All the preceding towns are in the Dutch possessions. There are several native states in the interior under Dutch protection. The residency of *Soerakarta*, or *Souracarta*, contains a total population of 400,000. The capital town of the same name, on the river Sols (which it is also sometimes called), has a garrison, a fort, and 100,000 inhabitants. *Yugyacarta*, or *Iocjocarta*, is a large and populous town, 60 miles south of Samarang, and the capital of a native sultan. In the eastern district of this territory is the fertile plain of Kediri. *Soerabaya* is the capital of a residency of the same name, on the north-eastern coast, and was formerly the residence of the governor of East Java. The town is on the strait of Madura, has 60,000 inhabitants, shipbuilding yards, and a fort. Population of residency, 970,000.

Inhabitants.—The natives of Java belong to the widely-spread race of the Malays. They are short, thickset, and robust. The religion is Mohammedanism, modified by Buddhism. Three different dialects of the Malay language are spoken on the island, but they have also an ancient sacred language, called Kawi, which contains a great number of Sanscrit words. The Javanese have a native literature, which, however, is not rich. They have also translations from the Sanscrit and Arabic. In civilization the Javanese are much superior to all other nations who inhabit the Indian Archipelago. They show skill in manufactures of cotton, silk, and shipping.

Java is extremely well adapted for an extensive commerce. The island itself is rich in productions, and its northern coasts, which are accessible to vessels all the year round, lie opposite the richest countries of Asia. Besides this, the Dutch government has made it the centre of all the trade which Holland carries on with its extensive settlements in the Indian Archipelago. Hence the transmission of native produce to other countries, and the importation of foreign commodities, are both very large. The imports comprise cottons, woollens, and other manufactured goods, wines, spirits, iron, hardwares, machinery, opium, and articles of luxury. The commerce is chiefly carried on by the Dutch East India Company, and the Netherlands absorb fully five-sevenths of the whole. Batavia is the centre of at least half of the general trade. The exports of Java produce, except to Holland, are comparatively trifling, caused by the restrictive duties charged on them when shipped to any other country. The chief articles are sugar, tea, coffee, indigo, rice, hides, tobacco, oil-cake, &c.

The total value of merchandise and specie imported into Java is nearly 4,000,000*l.* per annum, and that of the exports 4,500,000*l.*; almost the entire trade being with the Netherlands. In 1864 the exports from Java to the United Kingdom were valued at 16,749*l.*, consisting chiefly of rice and pepper. The value of British produce and manufactures imported into Java in the same year was 796,850*l.*, the principal articles being cotton and woollen goods, copper, iron, earthenware, and machinery.

Public improvements have of late years been much extended. A good road traverses the island in its entire length; many forts have been constructed in the interior; commercial stations planted in the

southern part of the island; and regular steam communication is kept up with Singapore.

Since 1833 the finances of the colony have been very prosperous, and upwards of 30,000,000*l.* were transmitted to the Netherlands from 1838 to 1863. In thirty years the annual revenue has risen from 2,500,000*l.* to 9,500,000*l.*, and the value of the exports in almost exactly the same ratio, being now about 9,000,000*l.* per annum. The marked prosperity of the island is due to the amazing industry with which the Dutch have promoted the growth of those articles to which it is specially adapted. Slavery was abolished in Java on September 20, 1859.

History.—Java was under Hindu sovereigns till 1478, when it was conquered by the Arabs. It contains the ruins of several considerable cities and temples, the principal being Mojopahit, the former capital of Java, and Boro-Budor, and various large structures of considerable architecture are scattered over the island. It is presumed that the Hindus settled here at an early period, Hindu monuments of antiquity being found.

The Portuguese reached Java in 1511, and soon after began to form small settlements. The Dutch established themselves at Bantam in 1575, and in 1602 the English erected a factory at the same place, which was the first possession of the English in the East Indies. But the English, as well as the Portuguese, were soon obliged to give way to the Dutch, who built the town of Batavia, and by degrees enlarged their dominion, until they succeeded, about the middle of the last century, in dividing the empire of the Susuhunan into two parts, and appropriating the greater portion of it to themselves. When Holland was united to the French empire, the British took possession of the island in 1811, but restored it to the Dutch, after the fall of Bonaparte, in 1816.

(See Junguhn's *Java*; Craufurd, *Dictionary of the Indian Seas*; Temminck's exhaustive work on the Dutch East Indian colonies, *Les Indes Néerlandaises*; D'Almeida, *Life in Java*; Sir J. Bowring, *Fortnightly Review*, January, 1866, &c.)

JAVELIN, among the classical ancients, a spear-like missile used both by the cavalry and infantry. It was sometimes five feet in length, and in a charge was darted at the enemy, often with destructive effect.

JAXT, or *Jagst*, a circle of Würtemberg, bordering N.W. on Baden, and N. and E. on Bavaria, has an area of 1986 square miles, and a population of 414,904 in 1861. The chief town is *Ellwangen*, a small place of 3000 inhabitants. The principal rivers are the Jaxt, from which it has its name, the Kocher, and the Rems. The greater part of the possessions of the princes of the House of Hohenlohe is situated in this circle. Besides Ellwangen the most important towns are—*Hall*, an ancient and picturesque town, situated on the Kocher; population, 6600. It is 35 miles from Stuttgart on the rail to Heilbronn; was formerly a free imperial city, inclosed by walls; and has seven churches, a town hall, endowed college, mint, hospital, two public libraries, and several sugar refineries. There are also soap and other factories, and a trade in oxen, hogs, and salt from the neighbouring springs, which yield 175,000 cwt*s.* annually. *Schorndorf*, a walled town, with a royal castle, near the Neckar, has carpet and tobacco factories and 3815 inhabitants; *Gmünd*,

a manufacturing town farther E., on the south bank of the Neckar, with 7000 inhabitants; and *Oehringen*, N.W. of Hall, the residence of the princes of Hohenlohe Oehringen; population, 3106.

JAY. [*Corvidæ.*]

JAYADEVA, a celebrated Hindu poet. The only extant poem of Jayadeva is entitled '*Gita Govinda*;' that is, 'the poem in honour of Govinda,' one of the names of Krishna, whose love for Râdha is described in a glowing and voluptuous manner. An English translation of '*Gita Govinda*' was published by Sir William Jones in the third volume of the '*Asiatic Researches*.'

JEAN or **JOHN II.**, son of Philip of Valois and Jeanne of Burgundy, ascended the throne of France upon his father's death in 1350. At the beginning of his reign he invited King Charles of Navarre to an interview at Rouen, and there arrested him, and put to death several lords of his suite. The brother of Charles applied to Edward III. of England for assistance. In 1355 Edward sent his son the Black Prince into France, who, after ravaging several provinces, was met by King John near Poitiers, with 80,000 men, the English being only 10,000 in number, on September 19, 1356: the French were completely defeated, and John was taken prisoner and conducted to London. Meanwhile the citizens of Paris revolted against the Dauphin Charles, and soon afterwards the peasants, or serfs, broke out into insurrection, with circumstances of frightful atrocity. This servile war, called *La Jacquerie*, lasted during the years 1357 and 1358, until the dauphin with a large force fell upon the peasants and massacred them by thousands. In May, 1360, peace was concluded at Bretigny between France and England, Edward giving up his claims to Normandy and France, and assuming the title of sovereign lord of Aquitaine, with the consent of the dauphin, who promised to pay a large ransom for his father. John was then restored to liberty; but he found so great an opposition among his nobles to the fulfilment of the conditions of the treaty, that he returned to London, where he took up his old quarters in the Savoy. He died in London, in April, 1364, and was succeeded in France by his son, Charles V.

JEAN-D'ANGELY, ST. [*CHARENTE-INFÉRIEURE.*]

JEDBURGH. [*ROXBURGHSHIRE.*]

JEDDAH, or **JIDDA**, a city of Arabia, situated on the east coast of the Red Sea, near Mecca, and a great entrepôt for foreign commerce. It has rendered itself notorious for the savage butchery of the Christian residents, including the English and French consuls, for which ample retribution was exacted by the bombardment of the town, and the public execution of eleven of the murderers. Although the resident population does not usually exceed five or six thousand, the number is usually increased by the influx of strangers on their pilgrimage to Mecca. Its public buildings are but of a mean description. The governor's house, a small castle with nine or ten guns, five mosques, and a few handsome Khans, are all that claim attention. The town, however, is one of the holy places of the

Mohammedan faith, and its sanctity is increased by the reputed tomb of Eve being in the neighbourhood. 'The caravans of Mecca,' says MacCulloch, in his 'Geographical Dictionary,' 'start daily; those to Medina, every forty or fifty days; the trade in grain is monopolized by the Egyptian government. Twice at least in every year Djidda is inundated with inhabitants, viz., on the arrival of the Indian fleet (about May), when merchants from all quarters pour in to purchase at the first hand; and during the hadj, when pilgrims come from all the African ports in vast numbers. In 1831 above 20,000 pilgrims landed either at Djiddo or Yembo, but mostly at the former. There is no manufacture in the town. Everything, for use as well as for consumption, is imported, and the occupations of the poorer as of the richer inhabitants consist almost exclusively of barter.'

JEDDO, or YEDDO. (Lat. 35° 40' N.; long. 139° 40' E.). The residence of the Tycoon, and the metropolis of the empire of Japan, is situated on the south-east side of Nippon, at the upper extremity of an inlet 20 miles long, which forms its harbour; a harbour equally capacious and secure, owing to the narrowness of its entrance, and the number of small islands which break the roll of the Pacific. The actual port is at Kanagawa, 16 miles nearer the mouth of the inlet, where the British consul resides. The establishments of the foreign merchants are planted at Yokohama, a neighbouring town, which has a quay and pier of granite.

The city of Yeddo probably stands second only to London in point of population and extent. It lines the shores of the inlet for about 10 miles, and extends 7 miles inland, but a considerable area is devoted to gardens and orchards. Long lines of booths enliven the streets, where a kind of daily bazaar is held for the sale of gaudily-coloured prints, maps (many of them copies of European charts), story-books, swords, tobacco pouches, and pipes for the humbler classes; and in the midst of which a fortune-teller may usually be seen, surrounded by a crowd of credulous listeners. Something very like the gambling table of our English fairs may also be seen in the same spot; but, judging by the stock in trade and the juvenile customers, the gambling would seem to be only for sweetmeats.

A fine view is obtained from the summit of a hill called Atango-gama, so called from the god Atango, to whom a temple is dedicated there. The picture that from this point breaks suddenly upon the traveller is very striking. The hill fronts to the bay, but with a couple of miles of valley intervening, thickly covered by streets and temples. To the left, and in a north-eastern direction, another 10 miles' interval of plain is in like manner filled up with a dense mass of houses, until the eye reaches a range of heights crowned by the Tycoon's castle. The whole *enceinte* of the official quarter, within a triple line of moats, is there, not only the official residence of his court, but the palaces of the feudatory daimios. This range excludes a still more extensive view of the city, which stretches away into the country on the other side, and may be traced from the point where the spur of the hill ends abruptly towards the bay, winding round the edge of the coast-line, and backwards up the valley, until it fades away in the remote distance. Behind, a broken series of hills and dales,

diversified by groups of temples, conceals yet another large quarter of the capital; a daimio's residence and park, or a few streets, spreading over the crests and straying into the hollows. Seaward the eye looks out upon the point which conceals Kanagawa; and across the line of batteries a couple of miles from shore, on to the distant edge of coast and mountain, some two or three leagues off, which forms the boundary on the hither side.

Fair to look on, says Alcock, is the capital of the Tycoon, thus nestled in a broad valley, girdled with green woods and crowned by undulating hills, sloping with a gradual descent to the edge of a bay, into which the Pacific seeks in vain to pour its stormy waters. Nature has barred the entrance with a breakwater of volcanic islands and verdurous headlands on either side. And to make it more secure, she has shoaled the whole gulf, so that five miles from the city it is difficult to find anchorage for a vessel drawing 20 feet—the best of all defences against assaults from without, whether the elements or a hostile fleet be the enemy.

The most populous part of the city is intersected by the river Okawa, which is spanned by a great central bridge. From thence are measured all the distances throughout the empire. Public baths are numerous and well frequented. In the suburbs tea-houses and gardens abound. There are shops for books, bronzes, lacquer goods, copperware, basket-work, mosaics on wood, paper, and old clothes. The houses are almost all one story high (a precaution against earthquakes), and of wood, which is the cause of numerous destructive fires. The Tycoon's palace crowns the highest hill (1200 ft.), and is surrounded by a triple moat. The residences of the daimios are of enormous extent, sometimes a quarter of a mile in length, in order to accommodate their crowds of retainers. These feudal barons are 264 in number, and have incomes which range as high as a million *kokoos*, or measures of rice, each *kokoos* being worth about 13s. 10d. in British money. The population of Jeddo was estimated in 1863 to be 1,700,000, comprising 572,840 merchants and artisans; the daimio's army, 25,000; the Tycoon's attendants, priests, monks, nuns, travellers, &c., 180,000.

JEEJEEBHOY, SIR JAMSETJEE, Bart., a famous Indian merchant and philanthropist, born at Bombay, 15th July, 1783. Although his parents were poor he received a good education, and having shown a special aptitude for mercantile pursuits, he at an early age became partner in business with his father-in-law, Framjee Nusserwanjee. His skill and enterprise were soon manifested in extensive and successful speculations in the produce of various countries, and in the prosecution of business he had made many long and hazardous voyages before he had completed his twenty-fourth year, when he became principal partner in the firm. Ere he had been twenty years in business, and when still young, he had amassed an immense fortune, which, instead of expending in personal display and luxurious gratification, he resolved to devote to the good of his less fortunate fellow-men. He expended vast sums on benevolent institutions and works of utility connected with his native city. Exclusive of private charity it has been computed he bestowed between the years 1822 and 1858 not less than a quarter of

a million sterling in the foundation, endowment, or support of undertakings of a benevolent character. Munificence so unprecedented did not escape the notice of her majesty Queen Victoria, who, as a mark of her esteem, conferred on him the honour of knighthood, the first instance of its being bestowed on an Indian subject. Other honours followed, and in 1857 he was made a baronet of the United Kingdom. In 1843 the queen sent him a gold medal set in diamonds. He died April 15, 1859, and was succeeded in the baronetcy by his eldest son, Cursetjee Jamsetjee Jeejeebhoy, who, while on a visit to this country in 1861, received signal marks of respect from the most distinguished personages and corporate bodies.

JEFFERSON, THOMAS. Thomas Jefferson was born April 2, 1743, at Shadwell, now in the county of Albemarle, in Virginia. He was educated at the college of William and Mary, at Williamsburg, then the capital of the colony, where he studied mathematics, ethics, and other branches of knowledge. In addition to his general acquirements, he made himself well acquainted with the best Greek and Latin writers, and to the end of his long life retained his ability to read them. Mr. Jefferson studied law under Mr. Wythe, then a lawyer of eminence. He made his first appearance at the bar of the General Court in 1767, at the age of twenty-four, about two years after the misunderstanding between Great Britain and the Colonies had commenced. He practised for seven or eight years in the General Court, when he was called away to more important duties by the political events that preceded the American Revolution. In 1769 he was elected a member of the House of Burgesses for the county of Albemarle. In the session of this spring the House unanimously came to resolutions in opposition to those which had been lately passed in England by both houses of Parliament on the affairs of Massachusetts.

In 1773, on the meeting of the Virginia Assembly in the spring, Mr. Jefferson was an active member in organising the Standing Committee of Correspondence and Inquiry, the main objects of which were to procure early intelligence of the proceedings of the British Parliament, and to maintain a constant communication among all the colonies.

On the 21st June, 1775, Mr. Jefferson took his seat in the General Congress, as one of the delegates from Virginia, and was appointed one of a committee for preparing a declaration of the cause of taking up arms. A part of the address which he drew up was finally adopted. In 1776 Mr. Jefferson was again a delegate to Congress, and one of a committee appointed to draw up a declaration of independence. Before it was shown to the committee, a few verbal alterations were made in it by Dr. Franklin and Mr. (afterwards President) Adams. After being curtailed about one-third, and receiving some slight alterations in the part retained, it was agreed to by the House, July 4, and signed by all the members present, except one.

From this time Mr. Jefferson's public life is interwoven with the history of the United States. He was governor of Virginia in part of 1779, 1780, and part of 1781, in which year the state suffered considerably from the incursions of Lord Cornwallis; and at the close of his period of office he narrowly

escaped being taken prisoner by Colonel Tarleton in his own house at Monticello, in the county of Albemarle.

In May, 1784, Mr. Jefferson was appointed by Congress minister to France, where he remained five years. His industry and methodical habits enabled him to devote a great deal of his time to the examination of everything that could prove beneficial to his countrymen.

He returned to America at the close of 1789, and in the next year he was appointed secretary of state by the president, General Washington. This office he held till the end of 1793, when he resigned. From 1793 to 1797 he lived in retirement. In 1797 he was elected vice-president of the United States, and in 1801 was chosen president, in place of Mr. Adams, by the House of Representatives, on whom the election devolved in consequence of the equal division of the electors' votes between Mr. Jefferson and Colonel Burr. He was elected a second time, and after fulfilling his term of eight years retired to his favourite residence at Monticello.

The nation was indebted to Mr. Jefferson's administration for the acquisition of Louisiana from the French for 15,000,000 dollars, and with it the free navigation of the Mississippi. Mr. Jefferson himself thought that the most important service which he rendered to his country was his opposition to the federal party during the presidency of Mr. Adams, while he was himself vice-president of the United States. His own administration was characterized by unwearied activity in the promotion of all those measures which he believed to be for the general welfare. He never allowed considerations of relationship or friendship to bias him in the selection of proper persons for offices; he always found, as he says, that there were better men for every place than any of his own connections.

The last years of his life were spent in retirement. But he continued his habits of early rising and constant occupation; he maintained an extensive correspondence with all parts of the world; received at his table a great number of visitors; and was actively engaged in the foundation of the University of Virginia, which was established by the state of Virginia, near Charlottesville, a few miles from Monticello. Though often baffled, he finally succeeded, by the help of his friends in the Virginia Legislature, in obtaining ample grants for the buildings, library, and the salaries of the professors.

He died July 4, 1826, just half a century after that day on which the Declaration of Independence was signed. Mr. Adams died on the same day. Mr. Jefferson is buried in the grounds near his own house. A simple inscription, which was found among his papers after his death, recording him as the author of the Declaration of American Independence, of the Statute of Virginia for Religious Freedom, and Father of the University of Virginia, is placed on his tomb. The fact of his having been president of the United States is not mentioned.

The latter days of Mr. Jefferson were embittered by pecuniary difficulties, which were owing in some measure to the neglect of his estates during his long absence on the public service; and in a great degree to an obligation which he incurred to pay a friend's debts.

When Mr. Jefferson was a member of the colonial legislature, he made an effort for the emancipation of slaves; but all proposals of that kind, as well as for stopping the importation of slaves, were discouraged during the colonial government. The importation of slaves into Virginia, whether by sea or land, was stopped in 1778, in the third year of the Commonwealth, by a bill brought in by Mr. Jefferson, which passed without opposition, and, as Mr. Jefferson observes, 'stopped the increase of the evil by importation, leaving to future efforts its final eradication.'

Mr. Jefferson married, in 1772, Martha Skelton, the widow of Bathurst Skelton. She died ten years after their marriage. One daughter, and a numerous family of grandchildren and great-grandchildren survived him.

JEFFREY, FRANCIS, an eminent Scotch judge and critic, was born at Edinburgh, 23rd October, 1773, and was the son of Mr. George Jeffrey, one of the depute-clerks of the Court of Session. He was educated at the High School of Edinburgh, from which he passed in 1787 to Glasgow College, where, under the able training of Professors Young and Jardine, his talents began to develop themselves with great brilliancy. In September, 1791, Jeffrey went to prosecute his studies at Oxford, which he quitted with great delight after a residence of only nine months, shocked at the dissipation and idleness which then prevailed in that seat of learning. In 1792, on his return to Edinburgh, he entered the Speculative Society, a step which brought him into close and familiar contact with Sir Walter Scott, Brougham, Horner, the marquis of Lansdowne, Charles and Robert Grant, and other master spirits of the age. He was called to the bar on the 16th of December, 1794. At this time he joined with Sidney Smith, Horner, and others, in establishing the *Edinburgh Review*, of which he continued sole editor for twenty-seven years, and by his labours undoubtedly established in England a new school of criticism. His professional progress was for some years very limited. The effect of his talents and industry was counteracted by certain unpopular peculiarities of manner, and by his political opinions, which at that period were in bad odour among both the middle and upper classes of society. 'Willing and waiting to work, but idle from want of employment,' he had frequent fits of depression and discontent. At one time he had thoughts of abandoning the law and settling in London 'as a grub;' and a little later he was anxious to obtain the chair of moral and political science in the College of Calcutta. In the midst of all his discouragements, however, he married in 1801 Miss Catherine Wilson, daughter of Dr. Wilson, professor of church history at St. Andrews, though the lady had no fortune and Jeffrey's professional income did not exceed 100*l.* a year. In 1804 he had the misfortune to lose his father and brother, together with his amiable partner—a blow which sunk deep into his heart, and made him, he says, 'inwardly sick of life.' Up to this period—though he had been nine years in practice—his professional income was only 240*l.* a year. Now, however, his prospects began to brighten, and he gradually won his way to the foremost rank in all the courts, civil, criminal, and even ecclesiastical. About the close

of the year 1813 Jeffrey married a second time. The object of his choice was an American lady, Miss Charlotte Wilkes, grandniece of the celebrated John Wilkes. Lord Cockburn says that almost the whole happiness of Jeffrey's future life flowed from his union with Miss Wilkes, and speaks in strong terms of the natural and cheerful pleasure which she diffused round her husband and his friends. In 1820, after a keen contest, Jeffrey was chosen lord rector of the University of Glasgow, an honour of which he was justly proud; and in 1829 his brethren of the bar elected him their dean, the highest distinction of the kind that can be conferred in Scotland. Immediately after his elevation to this office he withdrew from the management of the *Edinburgh Review*. In the following year the long reign of the tory administration terminated, and a whig government was formed under Earl Grey. Jeffrey, as indisputably the first Scottish lawyer of the party, was appointed lord-advocate, an office which he accepted with reluctance. A few weeks after his elevation he was elected member for what were termed the Forfarshire burghs, but was unseated on petition, and found refuge in Lord Fitzwilliam's burgh of Malton. He represented this place till after the passing of the reform bill, when he was returned, in 1832, by the Scottish metropolis, which he had unsuccessfully contested in 1830. As a speaker he can scarcely be said to have succeeded in the House of Commons. Jeffrey's parliamentary career lasted only about three years and a half. The most important measures connected with it were the Scotch reform bill, and the bill for the reform of the burghs of Scotland, both of which he prepared and carried through. The death of Lord Craigie caused a vacancy in the Court of Session, and Jeffrey was elevated to the bench in 1834. The remainder of his life was passed in the quiet discharge of the duties of his judicial office. He died on the 26th of January, 1850, in his seventy-seventh year. Mrs. Jeffrey survived him only a few months. Their only child was married to Professor Empson of Haileybury College.

Further details of this distinguished man's career will be found in Lord Cockburn's interesting 'Memoir,' whose perusal will impress the reader with a high opinion of the excellence of his character and the charms of his society. His wit was genial and sparkling; his play of fancy felicitous and inexhaustible. Of unimpeachable integrity, high and daring spirit, a delicate sense of honour, a generous temper, and a benevolent disposition, he was no less loved by his friends, than as a writer and man of letters he was admired by the public.

JEJUNUM. [INTESTINES.]

JELALPOOR, a town on the right bank of the Jhelum, in a fertile valley of the Punjaub, in lat. 32° 40' N., long. 73° 26' E. Here is one of the fords over the Jhelum, on the route from Afghanistan to Hindustan. It is a point of dispute whether here or higher up at Jhelum, was the scene of the battle between the forces of Alexander the Great and Porus.

JELLALABAD, a town of Afghanistan, in a fertile plain near the Cabool river, 78 miles E.N.E. of Cabool, on the route to Peshawur. It is famous for the heroic and successful resistance made here by the British troops, under Sir Robert Sale, in 1841-42. Its defences were destroyed at the British

evacuation of Afghanistan, in 1842. The stationary population is probably only about 3000, but it is greatly augmented in winter.

JELLY-FISH. [CILIOPODA.]

JEMAPPES. [HAINAULT.]

JENA, a town in the Grand-Duchy of Saxe-Weimar, is situated on the Saale, over which there is a stone bridge of nine arches, in 50° 56' N. lat., 11° 37' E. long. The ramparts and moats which formerly surrounded the town have nearly disappeared. Jena is the seat of a supreme court of appeal, and of several learned societies. It is, however, chiefly celebrated for its university, which was founded in 1557, and has a library of 100,000 volumes. There are in connection with it a botanic garden, a veterinary school, a school of midwifery, an anatomical theatre, a clinical institution, a collection of physical and mathematical instruments, a cabinet of minerals, an observatory, &c. It is the university of the whole of the Saxon states, and is supported by contributions from them all. Its income is nearly 6000*l.* per annum; and an academic honour obtained at it is much prized throughout all Germany. The population of the town in 1861 was 6984. Jena has acquired celebrity from the disastrous defeat of the Prussians by the French which took place near it on the 14th of October, 1806. [AUERSTADT; BONAPARTE.]

JENNER, EDWARD, the discoverer of vaccination, was born at Berkeley in Gloucestershire, on the 17th of May, 1749. He was the third son of the Rev. Stephen Jenner, vicar of Berkeley. At eight years of age Jenner was sent to school at Wootton-under-Edge, under the Rev. Mr. Clissold, and was afterwards placed at Cirencester, under the tuition of the Rev. Dr. Washbourne, where he received a respectable classical education. On leaving school he became the pupil of Mr. Ludlow, an eminent surgeon at Sodbury, near Bristol. His apprenticeship having terminated, he proceeded to London, where he prosecuted his professional studies under the immediate superintendence of John Hunter, in whose family he resided for two years. There can be no doubt that the intimacy which sprang up between the master and pupil, and which continued until Hunter's death, exercised a powerful influence on Jenner's subsequent career. The love of natural science, which with him was almost an instinct, was fostered and quickened into the highest degree of life and energy by the example and teachings of Hunter, who had already commenced the formation of that magnificent museum which forms the lasting monument to his fame. It was in such a field that Jenner's powers were cultivated. He became an expert practical anatomist, a careful and observant experimenter, a sound pathologist, and a finished naturalist. During the time of Jenner's residence with Hunter, in the year 1771, Captain Cook returned from his first voyage, and Jenner was recommended by Hunter for the service of arranging and preparing the specimens of natural history which had been collected by Sir Joseph Banks. The manner in which the task was accomplished showed so much skill and knowledge, that Jenner was offered the post of naturalist to the next expedition, which sailed in 1772. He declined, however, the appointment, and decided to return to Gloucestershire and fix his residence in the place of his birth,

VOL. VII.

where he took up his abode with his brother, and commenced the practice of his profession. The reputation he had brought with him from London, the great professional knowledge he evinced, his kindly disposition and manners, rapidly brought him practice. In March, 1788, he married. In the year 1792 Jenner retired from the more onerous duties of a country practitioner's life, and obtained the degree of M.D. from the University of St. Andrews. It was not long after this that he made the great discovery, which may be said to have eclipsed every other discovery of modern science in the amount of benefit it has conferred on the human race, and which has enwreathed the memory of Jenner with honours that time can never wither. The first incident in the story dates back to the time when Jenner, as the surgeon's apprentice, was pursuing his professional education at Sodbury. One day a young countrywoman applied at the surgery of his master for advice. The small-pox was casually mentioned in her hearing; she immediately observed, 'I cannot take that disease, for I have had cow-pox.' This assertion made a deep impression on Jenner's mind; it was the first time he had heard of what had been for many years a tradition amongst the peasantry in the dairy districts of Gloucestershire and other counties; he continued to think of it, and when, some time after, he was domiciled in London with Hunter, he mentioned the subject of cow-pox to him. It does not, however, appear that Hunter was impressed with the importance of the consequences which were involved in the popular observation. He mentioned the Gloucestershire tradition in his lectures on Jenner's authority. He likewise spoke of it to some professional friends, and it was noticed in other lectures of the time; but he never pursued the matter further. Jenner, however, never lost sight of it; he found the subject loaded with many obscurities and contradictions which he set himself to unravel, and he never failed to stimulate all his professional friends and acquaintances to apply themselves to its investigation. In this latter object he met with but little success. Determination of purpose was, however, a leading characteristic in Jenner, and regardless of the arguments and ridicule of his friends, he continued to prosecute his inquiries. He discovered that cows were the subjects of at least two eruptive diseases which were capable of producing sores on the hands of those employed in milking, and that to both these affections the name of cow-pox was applied. It was only one of these diseases, however, which gave immunity from small-pox. He ascertained also another most important fact, that in the case of the true cow-pox, it was only in a certain state of the pustule that virus was yielded capable of affording a protective power. He found that matter taken at a later period might induce a local sore, but that it failed in bestowing any safety from variolous contagion. It was in the year 1780 that he first disclosed the result of his inquiries to his friend Edward Gardner. In the year 1788 he took a drawing of the casual disease as it occurs on the hands of milkers to London, and showed it to Sir Everard Home and others. The subject attracted some attention; and Dr. Adams, who had heard of it from Mr. Cline, mentioned it in his work on Morbid Poisons, which appeared in 1795. It was not until

a year later, 1796, that Jenner was able to institute the first experiment, which proved that the disease might be communicated by artificial inoculation. The following is Jenner's own report of the experiment, extracted from one of his letters to Edward Gardner:—'As I promised to let you know how I proceeded in my inquiry into the nature of that singular disease, the cow-pox, and being fully satisfied how much you feel interested in its success, you will be gratified in hearing that I have at length accomplished what I have been so long waiting for, the passing of the vaccine virus from one human being to another by the ordinary mode of inoculation. A boy of the name of Phipps was inoculated in the arm from a pustule on the hand of a young woman (Sarah Nelmes) who was infected by her master's cows. Having never seen the disease but in its casual way before, that is, when communicated from the cow to the hand of the milker, I was astonished at the close resemblance of the pustules, in some of their stages, to the variolous pustules. But now listen to the most delightful part of my story. The boy has since been inoculated for the small-pox, which, as I ventured to predict, produced no effect. I shall now pursue my experiments with redoubled ardour.' The experiment above referred to was performed on the 14th May, 1796, a day still celebrated as an annual festival at Berlin. After multiplying his experiments, Jenner published his first Memoir in June, 1798. The progress of vaccination was darkened at the outset by various disappointments and obstacles. Objectors were numerous, and rival claims to the merit of the discovery were set up. But a high tribute to Jenner was paid as early as the year 1799, when a large number of leading physicians and surgeons signed an earnest expression of their confidence in the efficacy of the cow-pox. The discovery was soon afterwards promulgated throughout civilized Europe and America, and it was introduced into Asia by Dr. De Carro, at that time a physician of Vienna. Honours were showered on Jenner by foreign princes, and by the principal learned societies of Europe; the royal family of England exerted themselves to promote the cause of vaccination; and Parliament voted to its discoverer, in the year 1802, a grant of 10,000*l.*, and in the year 1807 an additional grant of 20,000*l.* The latter days of Jenner's were occupied in the dissemination and elucidation of his great discovery. He died of apoplexy at Berkeley in February, 1823. A statue to his memory has been recently erected by the French at Boulogne.

JENYNS, SOAME, was born in 1704, and died in 1787. He was educated at St. John's College, Cambridge; he was M.P. for Cambridgeshire in 1741; for the borough of Dunwich in 1754; and for the town of Cambridge from 1761 to 1780. In 1755 he was made a lord of trade, and he held that office in spite of political changes until its abolition in 1780. His poems, which consist of 'The Art of Dancing,' 1728, and 'Miscellanies,' 1770, are included in Johnson's 'Works of the English Poets.' His prose works are:—'A free Inquiry into the Nature and Origin of Evil,' 1756; 'View of the Internal Evidence of the Christian Religion,' 1776; 'Dissertations on various Subjects,' 1782. His works are collected in 4 vols. 8vo., 1790-93.

JERBOA. [MURIDÆ.]

JEREMIAH, one of the prophets of Judah, the writer of the book in the Hebrew canon which bears his name, and of that succeeding it, called 'The Lamentations.'

He was of the sacerdotal family, being the son of Hilkiah, a priest, whose residence was at Anathoth, a city of the tribe of Benjamin, about three miles north of Jerusalem. This we learn from the general title to his book of Prophecies (chap. i., ver. 1); and that title sets distinctly before us the period through which he flourished. He was called to the prophetic office, being then in his youth, in the thirteenth year of King Josiah, which, according to the received chronology, was 629 years before the Christian era commences. He continued in office till the eleventh year of King Zedekiah, that is, till 588 B.C. His contemporaries were in the earlier periods Zephaniah and Habakkuk, and in the later his era approaches near to that of Ezekiel and Daniel.

The book entitled his Prophecies is a collection of such prophecies or exhortations as he delivered at various times, mingled with relations of historical events. The last chapter, the fifty-second, is wholly historical, and is supposed to have been written by some other person, not improbably Ezra, and to be intended as a kind of introduction to the book of 'Lamentations,' which follows it. But the most remarkable circumstance relating to the composition of the book is this, that the various prophecies are put together without any regard to the order of time in which they were delivered. At the beginning we have the account of his call to the prophetic office, but we soon find prophecies delivered in the reign of Jehoiakim following others which were delivered many years after in the reign of Zedekiah. Jeremiah seems to have employed Baruch, his uncle's son, to commit his prophecies to writing.

The sacred books contain no later information concerning the prophet than that he was among those who went to Taphanhes. But some of the early Christian writers relate of him that he was stoned to death by his countrymen in Egypt for preaching against their idolatry.

JERICO. [SYRIA.]

JERICO, ROSE OF, is the popular name of a plant called by botanists *Anastatica Hierochuntica*. It is a native of Palestine and other parts of the East.

JERK, a word which, while continuing to be used as equivalent to 'sudden twitch or thrust,' is also employed as an adjective, in a widely different sense. Thus, *jerked beef* is meat cut into pieces and dried in the sun. In certain districts of South America, where the supply of animal food surpasses native consumption, it is customary to cut up the carcass into small pieces, and export them under this name. It is a well known fact, that neither flesh nor fruits lose much, if any, of their nutritive qualities in consequence of drying. Thus after having been dried, they can, by a simple process, be rendered easily edible.

JEROME OF PRAGUE, the friend and fellow martyr of John Huss, was born at Prague between the years 1365 and 1370. He studied in the universities of Prague, Heidelberg, Cologne, Paris, and Oxford, and obtained the degrees of master of arts and bachelor of divinity. His reputation for

learning was so great that Wladislaus II., king of Poland, commissioned him to organize the new University of Cracow in 1410, and Sigismund, king of Hungary, invited him to preach before him at Buda. He held the doctrines of Wyckliffe, attached himself to the cause of Huss, and denounced the abuses of the church. He trampled the relics under his feet, and excited the minds of the people so violently against the monks, that several of them were seized and kept in durance, and one of them was even thrown into the Moldau. When the bull of Pope John XXII. arrived in Prague, Jerome sent it through the city attached to the dress of a courtesan, and then caused it to be publicly burned along with some indulgences at the common pillory. When he heard of the treacherous imprisonment of Huss at Constance, he hastened to join him, but his devoted fellow-confessor had become a martyr before he arrived. The same tragical glory awaited himself. On his return to Prague, he was seized by the orders of the duke of Bavaria, and was carried back in chains. He was then cast into a dungeon and placed on trial. At first his firmness forsook him, and on the 23d September, 1415, he recanted his opinions, but subsequently abjured his recantation with horror, and he was condemned to death by the Council of Constance, on the 30th May, 1416. He heard his doom pronounced with the utmost composure, and died in the fire with a heroism worthy of the friend and fellow-worker of Huss, bearing witness to the truth with his latest breath.

JEROME, SAINT, accounted the most learned of all the Latin Fathers of the Church, was born about 340, and died in 420. He was a native of Pannonia, but came early to Rome, where he studied under the grammarian Donatus. He visited Gaul, where he remained some time, and afterwards travelled in Thrace, Pontus, Bithynia, Galatia, and Cappadocia. He also visited Jerusalem. In 382 he returned to Rome, having spent some time at Constantinople on his way. At Rome he became secretary to Pope Damasus. He eventually returned to the neighbourhood of Jerusalem, and took up his abode in a monastery at Bethlehem, and here it is believed that he died.

Many of the writings of Jerome are come down to us. Amongst the most valuable are, his treatise on the 'Lives and Writings of the elder Christian Fathers,' and his 'Commentaries on the Prophetical Books of the Old Testament,' on the Gospel of St. Matthew, and on several of St. Paul's Epistles. But his greatest work is a translation of the books of both the Old and New Testament into Latin, which translation has been always highly valued in the Latin Church, and is that known by the name of the Vulgate.

JERROLD, DOUGLAS, a distinguished dramatist and journalist, was born in London in 1803. His father was the manager of a theatre at Sheerness; but it does not appear that the stage, at that early period of his life, had any attractions for his son, who entered the navy as a midshipman under Captain Austen, brother of the well-known novelist, Miss Austen. At the conclusion of the war, however, he had to select another profession; and was placed as an apprentice with a London printer. Here he devoted himself to the study of languages, and to literary

pursuits. His first impulse for dramatic writing was the favourable reception of a critique on the opera of *Der Frieschutz*, which he had written for the newspaper on which he was employed as a compositor. Before he was twenty he wrote several dramatic pieces; among others 'More Frightened than Hurt,' which was performed at Sadler's Wells, and still keeps the stage. He was then engaged by the manager of the Coburg Theatre to produce pieces at a salary; but he soon afterwards went to the Surrey, where he produced the celebrated naval melodrama of 'Black-eyed Susan,' which had a wonderful run, and completely retrieved the fallen fortunes of that house. It also largely contributed to the fame and independence of the late T. P. Cooke, who played the principal character. It was afterwards performed for many hundred nights on the boards of the theatres royal, and had the run of nearly all the provincial theatres; but after all, the author's share of the immense profits thence arising did not exceed 70%. Jerrold now devoted his pen almost exclusively to dramatic compositions, and among other pieces he brought out 'Nell Gwynne,' 'The School-fellow,' 'The Housekeeper,' 'Bride of Ludgate,' 'Mutiny at the Nore,' and the 'Rent Day,' the last of which, founded on one of Wilkie's celebrated pictures, had a considerable run, and proved a source of profit to the author. Soon afterwards appeared his comedies of 'The Prisoner of War,' 'Bubbles of a day,' 'Time works Wonders,' and other pieces, which were played with considerable success at the Haymarket and the Princess'. His talents, however, were not confined to the drama; he applied them in a variety of ways to numerous compositions of a light and agreeable character, which were chiefly contributed to the magazines and newspapers. In *Blackwood* appeared his 'Men of Character,' and 'The Chronicles of Clovernook' in the *Illuminated Magazine*, of which he was editor. His ready wit appeared also in the various numbers of *Punch*; to which he contributed a 'Story of a Feather,' 'Punch's complete Letter Writer,' 'Punch's Letters to his Son,' and the 'Caudle Lectures.' He was afterwards engaged, at the earnest desire of the proprietor of *Lloyd's Newspaper*, to undertake the editorship of that journal at 1000*l.* per annum; and it is stated that on the assumption of Jerrold's name, it received during the first week an accession of 25,000 subscribers. He died in 1857, and was interred in the Norwood Cemetery. His works, which have been collected in eight volumes, exhibit great insight into character, much shrewdness of judgment, and a caustic wit. The style is sharp and epigrammatic, but philosophical views or luminous expositions of moral truth must not be looked for in any of Jerrold's writings.

JERSEY, an island in the English Channel, about 18 miles S.E. from Guernsey, between 49° 9' and 49° 16' N. lat., and 1° 58' and 2° 14' W. long. Its greatest length E. to W. is about 12 miles; its greatest breadth N. to S. is about 6 miles. The area is about 62½ square miles, or 39,580 acres, of which 25,000 are cultivated. The population in 1861 was 57,030.

The surface of the island has a gradual slope from north to south. On the north side the coast is abrupt, rising to the height of 100 to 200 feet, and

broken by a succession of small bays and coves. On the remaining sides it is less precipitous. There are several good bays, the chief being Boulay, St. Catherine, Grouville, St. Ouen, St. Aubin, and St. Brelade. Groups of rocks surround the island at various distances from it, and there are also many banks and shoals.

The surface is everywhere undulating. The valleys generally run from north to south; they are narrow at the north end, where the high ground forms an almost unbroken hill, and grow wider as they approach the southern coast, where they expand into several flats of good pasture land. The principal water-courses flow from north to south.

The high land consists for the most part of granitic rocks; the southern part of a mass of schistose rocks incumbent upon granite. The roads are numerous, wide, and well constructed, and traverse the island in many directions. The granite from the Mount Mado quarries, in the northern part of Jersey, is largely exported, and much esteemed in London for paving purposes.

The climate of Jersey, from its insular situation, is milder than that of other places under the same latitude, and the mean annual temperature (53°) is higher than that of any part of England. Wheat is the principal grain crop; barley is grown, and some oats; parsnips are extensively grown and used for fattening hogs and bullocks. Potatoes for exportation are widely and increasingly cultivated. Lucerne is one of the most valued crops, but the chief products are apples and pears—the whole island having the appearance of a continuous orchard. All the cows are of the Alderney breed, and are very carefully reared; but sheep and horses are comparatively neglected. Off the south-east coast are oyster-beds, fished by the islanders.

Vraic, or sea-weed, is used both for manure and fuel, and its collection is subject to very stringent regulations.

Jersey is divided into twelve parishes, in the diocese of Winchester. These are subdivided into 'vintaines' (scores), supposed to be so called from having originally contained twenty houses. Of these vintaines there are from two to six in each parish, and in all fifty-two.

The island has its own legislature—the 'States,' or Parliament, consisting of thirty-six members, chosen by the inhabitants, their acts being confirmed or annulled, in special cases, by the English governor. From the decisions of its royal court, the only appeal is to the sovereign in council. As in Guernsey, the laws of the island are very peculiar, being mainly derived from the ancient customary law of Normandy. Arrests take place without proof or affidavit, and it is only recently that the Queen's writ had any power, or that the Act of *Habeas Corpus* has been admitted.

The livings are in the gift of the crown, and are of small value. The principal educational establishment is Victoria College, where instruction in the highest branches of knowledge is imparted on moderate terms. There are also exhibitions at the Universities of Oxford and Cambridge.

The only manufactures in the island worthy of note are hosiery and shoes.

Steamers communicate frequently with Weymouth,

Southampton, Littlehampton, St. Malo, and Granville.

The military governor has under him usually about 300 regular troops, besides which Jersey has a militia of 2500 men, with an artillery battalion. The island is protected by numerous forts.

The native inhabitants speak a French *patois*, and preserve many Norman feudal customs, the Channel Islands having formed part of the Norman dominions, and remained attached to England since the Conquest. French is used in all legal proceedings, and also in the debates of the 'States,' but most of the residents can speak both English and French, as the former has long been taught in all the principal schools.

The trade of Jersey, owing to the privileges possessed by the islanders (there being no customs duties), is very considerable. The agricultural produce of the island, potatoes, apples, pears, fruit, cider, butter, cows, and other live stock, are sent to England in return for cotton and woollen goods, hardwares, cutlery, glass, about 20,000 tons of coal annually, and general merchandise. The foreign imports are wine, brandy, timber, &c.; the two former being supplied from France, from which Jersey is only about 16 miles distant. Particulars of the trade between the Channel Islands and Great Britain will be found in the article GUERNSEY.

There are three towns in the island, St. Helier and St. Aubin, both on the Bay of St. Aubin, and Gorey, on the east coast.

St. Aubin is situated in the western angle of St. Aubin's Bay, $4\frac{3}{4}$ miles from St. Helier. The town consists chiefly of one street of about 100 houses, with about as many more in different directions. There is a good pier, but the depth of water is not sufficient for large vessels. The place is defended by a small fortress, which is insulated at high water. Population in 1861, 800.

St. Helier is toward the S.E. point of St. Aubin's Bay, and fronts the sea. In external appearance it is much on a level with English country towns of the same size, except that the ramparts of Fort Regent, overtopping the buildings, give to the place the appearance of a continental town. The principal public buildings are—the theatre, new court-house, workhouse, gaol, and Victoria College, opened in 1852. There are two fortresses: Elizabeth Castle on a rock in the bay opposite the town, and Fort Regent, a fortification commanding the town, of considerable strength. It was constructed about 1806, at a cost of 800,000*l*. The population of the town in 1861 was 29,528. The harbour is formed by two piers, jutting out into the bay, at the south end of the town. The town is the residence of many retired officers of the British army and navy, foreigners, and families of limited income from Great Britain. It has also a large number of summer visitors from both England and France. There is an active trade with England, France, and the West Indies; and it is the seat of the 'States,' or representative parliament of Jersey. A submarine telegraph to England has been in working operation since 1858. It is within ten hours of Southampton and Weymouth, and twelve or fourteen hours of London by steamer and railway.

Gorey is situated on Grouville Bay. The importance of Gorey depends on its oyster fishery, in which

upwards of 250 boats are employed. In the neighbourhood of Gorey is Mont Orgueil Castle, once the principal fortress of the island, on a headland between St. Catherine's Bay and Grouville Bay.

The other places in the island are mere hamlets, grouped round the churches of the several parishes, or scattered along the coast. Much of what has been said of the state of society and the constitution of the local government in Guernsey will apply to Jersey. [GUERNSEY.]

Jersey, the *Cæsarea* of the Romans, is said to have been originally called Augia. In the reign of Edward III. this island was attacked by Du Guesclin, constable of France, but the arrival of succours from England prevented him from succeeding. In December, 1780, the Baron de Rullecourt landed with 700 men, took possession of St. Helier, and made the lieutenant-governor, Major Corbet, prisoner, and induced him to sign a capitulation. The British troops and island militia, under Major Pierson, next in command, refused to recognize the capitulation, and, attacking the French, killed Rullecourt, with the greater part of his men, and obliged the rest to surrender. Major Pierson fell in the beginning of the attack.

(The best work of reference on Jersey is Professor Andey's *Channel Islands*, London, 1862. See also Dendy's *Islets of Britain*, and Sandford's *Guide to the Channel Islands*.)

JERSEY, NEW. [NEW JERSEY.]

JERUSALEM (Arabic, *El-Kuds*, 'the Holy,' Lat. *Hierosolyma*), the sacred city, which for every Christian, no less than for every historical student, must always possess an absorbing interest, is situated in Palestine, now a portion of Asiatic Turkey, in the pashalik, and about 125 miles S.S.W. of Damascus, at an elevation of 2500 feet above the sea-level. Lat. $31^{\circ} 41' 43''$ N.; long. $35^{\circ} 13'$ E. Population, 17,000. An elevated limestone plateau, of barren character, and broken up by alternate ridges and ravines—in some places utterly sterile and desolate, as if sown with salt, in others clothed with an attractive mantle of olive groves and luxuriant gardens—stretches from the plain of Esdraelon towards the southern extremity of the Dead Sea. Nearly on a level with the watershed which separates the feeders of the Mediterranean and the Dead Sea, rises the loftiest crest of this undulatory table-land, sloping somewhat abruptly towards the rising sun, and finally terminating on the brink of the ravine which is known as the valley of Jehoshaphat. The bottom of this valley forms the channel of the brook Kedron—a winter torrent, completely dry for the greater part of the year—and on the opposite side swell the green ridges of the Mount of Olives. Southward runs another ravine, the valley of Hinnom, also watered by a rain-fed stream, which joins that of Jehoshaphat, and is itself a continuation of the shallower valley of Gihon on the western side. Between these ravines, and dominated over by the Mount of Olives, clusters the modern city of Jerusalem, divided into two equal portions by the Tyropæon, or valley of the Cheesemongers, which are again subdivided by two transverse glens or hollows; so that, in all, there may be distinguished four separate ridges or hills, Zion, on the S.W.; Acra, on the N.W.; Bezetha, on the N.E.; and

Moriah, on the S.E. The culminating point of Zion, which is only partly inclosed within the present walls, rises about 300 feet above the lowest portion of the adjoining valleys, 2535 feet above the level of the Mediterranean, and 8835 feet above that of the Dead Sea.

From Mount Olivet is obtained the finest view of the city as a whole, a view thus graphically described by Dr. Macleod in a recent work:—Towards the east, and between us and the Dead Sea, we see the wilderness of Judea, bare, bleak, and desolate, as would be the rocky bottom of the sea if upheaved and left to bleach beneath a burning sun. We see also a bit of the Dead Sea, more than 3000 feet below us, 'lying dead in its trough.' Though about twelve miles off, it looks very near. It appears hot and steamy, with a misty haze hanging over it. We cannot but associate all that is wild, lonely, and mysterious, with this dismal lake. It does not suggest one noble thought, one act of greatness or goodness, done by man or woman alive or dead, to shed over it a redeeming ray of glory. We can also trace the course of the Jordan, from its line of green vegetation. The memories of the great and good which it recalls are a relief to the mind. Its entrance into the Dead Sea seems like life losing itself in death. There rises also before the eye, the great eastern wall of the ridge of Moab, the separation between modern civilization and almost unknown Arabia, with its ancient cities, far-spread pasture lands, arid wastes, powerful tribes, and primeval traditions. Standing on Olivet, one fully realizes the contrast between East and West, with Palestine as their connecting bridge.

From this point, continues Dr. Macleod, one also takes in at a glance the general topography of Jerusalem. He is struck with the sort of promontory abutting from the general table-land on which it is built; with the wonderful defence against ancient modes of warfare afforded by the valleys that, like deep ditches, surround it on east and south, hindering any enemy from coming near its walls; with the strong military positions which were afforded by the principal eminences within the city, such as the temple area, separated from Zion by the valley of the Tyropæon, and the high ground of Acra and Bezetha, eminences distinctly visible. The hills that surround Jerusalem are also visible, not only in the arching sweep of Olivet and its spurs, but further off in a ridge which stands as a wall between the city and the heathen tribes dwelling by the sea. One can see how it rested like an eagle's nest on a rocky eminence, or like a lion's lair, visible from every side, yet not to be approached with impunity. Its compactness must also have been one of its marked features. There were no human habitations beyond its gates. There it lay like a chess-board, with its men, bishops, knights, and castles, within the walls, while all beyond was painfully empty and bare; limestone everywhere, with little of green to relieve the eye.

South of the Mount of Olives, and, in fact, a continuation of it, rises the Mount of Offence; south of the valley of Hinnom, the Hill of Evil Counsel; and to the north extends a billowy roll of mountainous summits, so that Jerusalem, as a city, is almost entirely encompassed with lofty heights.

Anciently its walls included the four hills already mentioned, and a considerable area to the N. and W. of them, but those now standing comprise a less extensive space, and have a circuit of only 2½ miles. They were built by the Turks about three centuries ago, and vary in height from 20 to 50 feet. Constructed of great hewn stones, they are surmounted by a stout breastwork, loopholed and battlemented, flanked at regular distances by strong towers, and pierced with four gates. These are:—on the E., *St. Stephen's Gate*, called by the Turks *Bâb-es-Sabat*, or 'Gate of the Tribes,' and opening on the brook Kedron, the Mount of Olives, and the picturesque village of Bethany; on the N., the *Gate of Damascus*, *Bâb-el-Amud*, 'Gate of the Pillar,' in the line of the great road which leads to the beautiful Syrian city; on the S., the *Gate of Zion*; and on the W., the *Jaffa*, *Hebron*, or *Bethlehem Gate*. Near the latter, and on the loftiest point of Mount Zion, stands a citadel (also called David's Castle), and the Tower of Hippicus—a massive, battlemented, and turreted stronghold.

Entering the city we shall find that notwithstanding its sublime associations, and the natural beauties of its position, it presents little in itself to attract or interest the pilgrim. The streets are narrow, dark, and ill-paved; the houses, though built of stone, and with flat roofs, sometimes crowned with small domes, are dark, windowless, and prison-like; and a large portion of the interior consists of ill-built churches, monasteries, and mosques. The principal street is the well-known *Via Dolorosa*, or 'Way of Sorrow,' so named because the Saviour is said to have traversed it, bearing his cross, when passing to the last scene of his sacrificial career on Mount Calvary. It extends from E. to W. across the hill of Acra, bends to the N. for a short distance, and again turning eastward, winds between the ridges of Bezetha and Moriah to St. Stephen's Gate. Another street of some importance runs in a direction nearly parallel to the former, from the Bethlehem Gate on the E., between the hills of Acra and Zion, to the bazaar, and afterwards continues to the hill of Moriah. A highway from the Damascus Gate, through the centre of the city, and in a southerly direction, as far as the Gate of Zion, crosses these two streets nearly at right angles. Here, and in the bazaar, congregate the Jerusalem shopkeepers, who are mostly Christians, and exhibit a commendable activity in the disposal of their wares.

To enumerate all the interesting localities within the walls of the Holy City, the very metropolis of Christian faith and feeling, would be impossible in the narrow space to which we are necessarily confined. The first to which the Christian traveller directs his steps is the inclosure of Moriah, now called by the Mohammedans *El-Haram-es-Sherif*, or 'the noble sanctuary,' and only thrown open to Christian visitors since the Crimean war. Its general shape is that of a regular parallelogram, its greatest length being 1500 feet, and its greatest breadth about 1000. On all sides massive walls surround it; some of them to the north and west serving also as walls of houses, which belong chiefly to civil or ecclesiastical officials. On the east and south they now form a portion of the city walls. Of this wide and open area, a small space only is

occupied by buildings. Nearly in its centre stands the *Mosque el Sakrah*, or 'Dome of the Rock,' and at the south end the *Mosque el Aksah*.

This sacred area is overgrown with rich grass, and pleasantly besprinkled with the shadows of cypresses, olives, and other trees. But why is it sacred? Because it undoubtedly includes the site of the Temple, that temple in which Christ taught, and which was at once a symbol of the Old Testament and the New. A portion of this site is now occupied by the Mosque of Omar, a stately octagonal structure, seated on an elevated terrace, and approached by four porticoes, one of them graced with a superb marble colonnade, lighted by forty-eight windows of richly coloured glass, and crowned by a dome of magnificent proportions. Some remains of the great Jewish sanctuary are probably built up into this 'holy place' of the followers of the Crescent. Mr. Fergusson (and few living authorities are entitled to more respect), is, however, of opinion that the mosque was never intended originally as a place of Mohammedan worship, but was raised by the Emperor Constantine as a church over the Sepulchre of Christ. This sepulchre he finds in a cavern cut out of the living rock on which the mosque is built, and the summit of which rises above the floor of the cavern, like a flat boulder, about 60 feet long and 50 feet broad, which lies immediately under the dome, and within the circle of marble pillars supporting it. An open door on the south-east side leads by a few steps down into a vaulted chamber, hollowed out of the rock, about eight feet high and fifteen feet square, and here, according to Mr. Fergusson, the body of our Lord was laid by loving and reverent hands.

The tomb usually identified with this memorable event is contained, however, in the so-called church of the Holy Sepulchre, which stands on the northern ridge of the hill of Acra, and a short distance to the south of the *Via Dolorosa*. There can be little doubt that in this matter the popular tradition is erroneous, although the real site of the Holy Sepulchre is yet a matter of a keen and apparently endless controversy. It may possibly be resolved by the present explorations in Palestine. The church of the 'Holy Sepulchre,' so called, is a Byzantine pile of small architectural merit, but remarkable for the splendour of its internal decorations, was built by Helena, the mother of Constantine the Great.

The other edifices of note are the convents; such as the Armenian, which can accommodate a thousand guests, the Latin, the Greek, and the Coptic; a chapel which marks, it is said, the site of the house of Annas; a building opposite the Gate of Zion, called the house of Caiaphas; and the lofty mosque which covers, according to the legend, the tomb of the sweet singer of Israel.

Other localities there are whose associations cannot fail to endear them to the pilgrim, but of which we must restrict ourselves to a mere enumeration: such as the Pool of Bethesda, once visited by angels, but now a plain, dry, tank-like inclosure, about 360 feet long, 30 broad, and 50 deep; the Pool of Siloam, situated near the confluence of the three valleys of Jehoshaphat, Hinnom, and Tyropæon; the *Aceldama*, or 'Field of Blood,' purchased by the 'thirty pieces' which rewarded the treachery of Judas, and placed on the southern margin of the Hinnom valley; the

so-called Fountain of the Virgin; the tombs of the Kings, clustering on the brow of the hill above the brook Kedron; the pillar of Absalom, on the eastern edge of the valley of Jehoshaphat; the beautiful Pool of Hezekiah; and, above all, the memorable Garden of Gethsemane, situated at the base of the Mount of Olives, east of the brook Kedron, and still adorned by groups of olive trees of such antiquity that it is not improbable they waved to and fro in the wind on the very night of our Lord's last agony.

A few words must be devoted to the principal events in the history of Jerusalem.

Supposing it, as many authorities see good reason for doing, to be the Salem of Melchizedek, it must have existed about 2000 years before Christ's nativity. We first find it mentioned, under its present appellation, about B.C. 1500, when Joshua captured it from the Jebusites. The latter, however, retained possession of the citadel till the time of David, who, having driven them forth, took up his residence in the ancient fortress, and elevated Jerusalem into the capital of his kingdom. He adorned it with many edifices, all of which were eclipsed in glory and splendour by the first Temple, raised by Solomon at the divine command, and sanctified by a symbol of the constant presence of the All Powerful. After a long period of pride and prosperity the sins of its inhabitants called down the judgment of heaven, and the City of David was successively the prize of the conquering hosts of Egypt, Assyria, and Babylon. It was captured by Nebuchadnezzar B.C. 588, who razed it and its temple to the ground, plundered it of its wealth, and bore off its people to captivity. Seventy years of woe and degradation elapsed, and Cyrus then restored the Jews to their desolated land; Jerusalem was rebuilt, under the leadership of Ezra, and the temple rose again from its ashes, though far inferior in splendour to Solomon's glorious pile, B.C. 515.

On the dissolution of the Macedonian empire, Judea was invaded, and the Holy City captured, by Ptolemy Soter, who carried numbers of its inhabitants to Alexandria. Then arose the patriotic chiefs, known as the Maccabees, who delivered it once more from the yoke of the stranger, in 165 B.C. Its independence, however, vanished like a dream, for Rome soon swallowed up the Holy Land into her ever-widening empire, and her sovereigns, though nominally free, paid tribute to the Roman rulers. Then came the Messiah, and forty years after the Jews had denied and crucified Him, the last vestige of Jewish liberty disappeared. The armies of Rome poured into Judea, and under the leadership of Titus Jerusalem was beleaguered, stormed, and captured, A.D. 70. The remarkable events and unutterable horrors of that famous siege have been told by Josephus with graphic vigour. In 136 the Emperor Adrian finally destroyed the city, ploughed up its surface, and raised in its stead the Roman colony of *Ælia Capitolina*.

But Jerusalem seems indestructible. Its sacred name was in due time restored; and when Rome became Christian, the city which had witnessed the miracles and death of Christ naturally rose into importance in the minds of those who had accepted the truths preached by Christ. Helena, the mother of Constantine the Great, embellished and enriched

it, founding the church of the Holy Sepulchre; and it enjoyed a prosperous career under the fostering sway of the Byzantine emperors until captured by the Caliph Omar and his Moslems in 636.

Nevertheless, it continued to attract to its holy places a great throng of Christian pilgrims, who suffered at the hands of the Mohammedans the cruellest persecutions, and were compelled to witness the open and studied desecration of sacred localities which had for them an unspeakable charm. To deliver the Holy Land from these indignities—from the shadow of the Crescent—now became the ardent dream of every true follower of the Cross; and a crusade, or holy war, was accordingly preached by Peter the Hermit and the Roman Church with so much energy and persistence, that at length the mind of Christendom was thoroughly aroused, and its heart lit up by a kindling fire. Kings, princes, barons, knights, burghers, men-at-arms, all poured forth to rescue Jerusalem from the Saracen, and under the guidance of Godfrey of Bouillon, succeeding in their noble enterprise, they established a Christian monarchy in 1099, with Godfrey for its first and ablest sovereign. This kingdom, beset by powerful foes without, distracted by internal convulsions, and neglected by the European powers, could not long maintain its ground, and in 1187 was finally overthrown by the great Turkish sultan Saladin. From that time to the present Jerusalem has remained under the domination of the Mohammedans.

For full details as to the history, topography, and antiquities of the Holy City, we recommend the reader to consult Josephus, *Antiquities*, and *Wars of the Jews*; Milman, *History of the Church*; Gibbon, *Decline and Fall of the Roman Empire*; Mills, and Michaud, *History of the Crusades*; Dr. Robinson, *Researches in Palestine*; Wilson, *Lands of the Bible*; Fergusson, article *Jerusalem* in Dr. Smith's *Dictionary*; Dr. Williams, *Holy City*; Rev. W. Sandies, *Sinai and Jerusalem*; Levin, *Siege of Jerusalem*; Finlay, *Greece under the Romans*; Porter, *Handbook to Syria and Palestine*; Dean Stanley, *Syria and Palestine*; Dr. Norman Macleod, *Eastward*; Hepworth Dixon, *The Holy Land*; Chesney, *Euphrates Expedition*, &c. An association of gentlemen interested in these subjects has recently been formed (the 'Palestine Exploring Society'), under the most favourable auspices, for the thorough examination of the various localities connected with Christian history, and an expedition despatched at its cost has already reached the Holy Land and commenced its well-directed researches. We may, therefore, expect that much new light will shortly be thrown on the antiquities of Jerusalem.

JERUSALEM ARTICHOKE. The name of a plant, a species of *Helianthus*, belonging to the natural order *Compositæ*. It is a well known culinary plant, its tubers affording a wholesome food, somewhat akin to the common potato.

JERVAS, CHARLES, a portrait-painter, was born in Ireland about 1675. He studied with Kneller in London, and also in Paris and at Rome. He returned to London about 1708, where, through the praise and friendship of Pope, he was much employed, though his chief ability as a painter seems to have been his skill in copying: some of his copies after Carlo Maratti are, according to Walpole, equal to

the originals. Jervas died on the 2nd of November, 1739.

JERVIS, JOHN, Earl of St. Vincent, was born at Meaford in Staffordshire, January 9, 1734, O.S.; entered the navy at ten years old; rose to be captain; fought in Keppel's action in 1778; and captured the *Pégasé*, French 74, in 1782, for which he received the order of the Bath. On the breaking out of the French revolutionary war, he sailed in command of a squadron to reduce the French West India Islands, and captured Martinique, Guadeloupe, and St. Lucia. He was promoted to be Admiral of the Blue, June 1, 1795, and in the autumn took command of the Mediterranean fleet, with which he intercepted and defeated the Spanish fleet off Cape St. Vincent, on February 14, 1797, for which he received the thanks of both houses of Parliament, and was raised to the peerage by the title of Earl of St. Vincent and Baron Jervis of Meaford, and received a pension of 3000*l*. In 1798 the mutiny which broke out in the Channel squadron spread to the Mediterranean fleet, but was suppressed by his judicious and decisive severity. In 1801 he was made first Lord of the Admiralty on the formation of the Addington ministry, and at once set himself vigorously to retrench extravagant expenditure and to reform abuses. On Mr. Pitt's return to office, in May, 1804, he placed Viscount Melville at the head of the Admiralty. Earl St. Vincent again took command of the Channel fleet in 1806, in Fox's administration, but held it only for a year. He was appointed admiral of the fleet on the day of George IV.'s coronation, July 19, 1821, and died March 15, 1823, in the ninetieth year of his age. A monument has been erected in honour of him in St. Paul's Cathedral.

JESUITS, SOCIETAS JESU, the name of a celebrated religious order which was formed towards the middle of the sixteenth century. Ignatius or Inigo Loyola was a Biscayan officer of noble birth, in the Spanish army, at the beginning of the reign of Charles V. Being wounded in the defence of Pampluna, then besieged by the French and the Navarrese, he underwent a long and tedious confinement. Loyola was a man of enthusiastic mind; he had been fond of the world, and immersed in gallantry and pleasure; but enforced meditation now decided him upon a life of piety and religious labour, and he conceived the plan of establishing a religious order, which should be entirely devoted to the following objects:—1. The education of youth. 2. Preaching and otherwise instructing grown-up people. 3. Defending the Catholic faith against heretics and unbelievers. 4. Propagating Christianity among the heathens and other infidels by means of missionaries. Ignatius, having promulgated his views, procured some associates, and, after overcoming many impediments, repaired with his friends to Rome in 1537, where he laid before Pope Paul III. an outline of the institutions and regulations of his intended order. Loyola having been a military man, these rules were based upon the principles of a strict subordination, carried through several gradations, terminating with the *præpositus generalis*, or general superior, who was to have absolute sway over the whole society, and from whose decisions there was to be no appeal, except to the pope. Paul III. approved of the plan, and it was decided that the new order should

be called the Society of Jesus, that the members should wear no monkish garb, but dress in black, like the secular priests, and should in fact differ essentially from the monastic orders then existing. The bull of the pope authorizing the new society was issued in 1540. The original 'Constitutions' of Ignatius were written in Spanish, but afterwards translated into Latin. The first edition of them appeared at Rome, 'Constitutiones Societatis Jesu,' 1588, after the death of the founder, who expired on the 31st July, 1556. At his death the society was already established in Italy, Spain, Portugal, and Germany, and had above one hundred schools, besides numerous missionaries in the East and in Africa and America. Ignatius was succeeded as general of the Society by James Lainez, a man of more extensive information than his predecessor. It is to Lainez that the principal share in framing the 'Constitutiones' is attributed.

The constitution and regulations of the society have undergone scarcely any modification since its establishment. The body consists of four classes—professed, coadjutors, scholastics, and novices. The training is very protracted and severe, and the administrative and executive government of the society is such that the character, conduct, and position of each member is always well known to the general superior—he being furnished with quarterly, and in some cases even monthly, reports on the subject. The duty of obedience is carried to the extreme; and the system of training applied to the formation of 'professed' members shows the most profound knowledge of the human heart, and the most correct appreciation of the religious instincts and impulses of mankind. The habits necessary to inspire confidence and disarm prejudice and suspicion were carefully cultivated; and the manner in which some of the members availed themselves of this art in after life brought upon the society the obloquy of having furnished a new ethical term to nearly every European language; and when there is now occasion to denounce any course of conduct as guileful, disingenuous, or traitorous, it is often termed Jesuitical.

The opponents of the society allege that, in addition to the published regulations of their founder, the more advanced Jesuits are bound by a code of secret laws—*monita secreta*. In fact, a work purporting to contain these secret instructions was published at Cracow in 1612; and has been repeatedly reprinted since; but its authenticity has been over and over again denied by the society, and impartial Protestant critics now generally admit that the work must be regarded as spurious.

The Jesuits, very shortly after their establishment, began to play a distinguished part in the affairs of Europe. Lainez was sent by the pope as his legate to the Council of Trent, and he was the opponent of Beza at the Conference of Poissy in 1561. Soon afterwards, notwithstanding the opposition of the University of Paris, they obtained permission from Francis II. to open colleges and schools in France. The Jesuits taught gratis, and the university, whose courses of lectures were paid for, was jealous of them, and attacked them repeatedly.

During the war of the League the Jesuits opposed the claims of Henri IV., as being a heretic; but on suspicion of having been accessory to two attempts

which were made on his life, the Parliament of Paris decreed their banishment in 1594; but in 1603 Henri IV. recalled them.

The missions of the Jesuits form an important part of the history of their society. The first attempts by Xavier in India were premature, but he served as a pioneer to prepare the way for others better qualified for the task, and the Jesuits formed in time numerous Christian congregations in Japan. The history of the Japanese Christians, and their extermination in 1637, is found in Bartoli, '*Historia della Compagnia di Gesu*,' '*Il Giappone, seconda parte dell' Asia*.' In China the Jesuits were likewise successful, and their establishment there has been more durable. Although persecutions broke out against the Christians in China, yet the Jesuits never entirely lost their hold there. In Paraguay the Jesuits had an open field for the display of their abilities and principles. They formed, on the banks of the Paraguay and the Parana, a flourishing community of Indian converts, who are said to have amounted to more than 100,000, and governed them for a century and a half in peace and happiness; but in 1750 an attempted transference of the sovereignty of the territory from Spain to Portugal led to an order from the Spanish government that the Jesuits and their Indian pupils should abandon their homes, and remove to some other part of the Spanish territories. The Jesuits were prepared to obey, but the natives refused to submit, and resisted the Portuguese and Spanish forces which were sent against them; and although a subsequent change in the diplomatic relations of the two countries left the Indians in possession of their country, yet the Jesuits were falsely accused of having encouraged what was styled the rebellion. This and some other causes of offence occasioned the Portuguese minister Pombal, in 1759, to issue an order for the expulsion of the society from the Portuguese territories, and for the confiscation of their property. The order was executed with the greatest inhumanity both in Portugal and Brazil.

France followed next in the same course of proscription. The Jesuits had from various reasons become unpopular with the people, the Parliament, and the minister Choiseul; but the enmity of Madame de Pompadour was productive of more serious consequences. Pretences were easily found, and in 1764, by an order of the king, the society was entirely suppressed in France, and their property was confiscated; but a small pension was given to the members, who were allowed to remain dispersed in the country, on condition of swearing to renounce the society and its institutions.

Their fall in Spain took place three years later. Choiseul is said to have contributed to it by persuading Charles III. that an insurrection which broke out in Madrid in 1766 was the work of the Jesuits. On the 31st of March, 1767, the colleges and houses of the Jesuits throughout Spain were surrounded at midnight by troops, sentinels were posted at every door, the bells were secured, and the king's commissioners, having roused and assembled the respective communities in the refectory, read to them aloud the royal decree which expelled them from Spain.

In the following year, 1768, the king of the Two Sicilies and the duke of Parma suppressed the

Jesuits' Society in their dominions. It still continued in the Papal States; but on the 21st July, 1773, the Pope (Ganganelli) issued a bull declaring the said society to be suppressed and extinct.

In consequence of this bull, the Jesuits were likewise banished from the Sardinian monarchy, the Austrian dominions, and every Catholic state. Two powers only, Prussia and Russia, one Protestant and the other Greek schismatic, allowed the fathers an asylum, and continued to intrust them with the education of their Catholic subjects.

After the society had been suppressed for about thirty years, several attempts were made at the beginning of the present century to re-establish it. And at last, after his restoration in 1814, Pius VII. issued a bull solemnly re-establishing the society as a religious order, under the constitutions of St. Ignatius. In France they had reintroduced themselves in a kind of clandestine manner after the Restoration, upon which a great outcry was raised, and they were again expelled in 1830. They are now tolerated in that country on sufferance, rather than as having any recognized legal authority; but are nevertheless numerous and influential, and their educational establishments hold the very highest rank.

In Russia the Jesuits were expelled by a ukase of the Emperor Alexander, in June, 1817, upon the charge of intriguing and of making proselytes among the members of the established Greek Church, and are still excluded from that empire. They have, however, re-established themselves in other European countries; and, judging from a return published by them in 1865, their numbers would seem to be rapidly increasing. According to this document the number in the Roman States is 475, of whom 385 live in the Holy City, and the others in the colleges or houses of Comarca, Velletri, Frosinone, and Viterbo. At the end of the year 1864, the total number of members of the Company of Jesus was 7728, that is to say, 190 more than in 1863. The Jesuits are divided into twenty-one provinces, of which four belong to France, five to Germany, Holland, and Belgium, two to Spain, five to Italy, one to Mexico, and the others to England, Ireland, and the United States. The total number of Jesuits occupied in the foreign missions was 1532, or 240 more than in 1863, and of that number twenty-eight are on missions in Europe, 296 in Asia, 213 in Africa, 726 in North America, 199 in South America, and fifty-five in Oceania. In 1841, the Jesuits in the whole world numbered only 3563, and at the end of 1864 they had more than doubled. But large as this number may appear it is insignificant as compared with that of the former members of the Society. At the celebration of their first centenary they numbered 13,112, distributed over thirty-two provinces; and at the date of their general suppression, a century later, they had increased to 22,589, and were possessed of twenty-four professed houses, 669 colleges, 176 seminaries, sixty-one novitiates, 335 residences, and 275 missionary stations in heathen countries, or in the Protestant States of Europe.

Whatever their faults may have been elsewhere, there can be no doubt that in China, Japan, the Philippine Islands, and in South America, the Jesuits did much for the civilization and welfare of the inhabitants.

The Act of the 10th Geo. IV., c. 7, which is entitled 'An Act for the Relief of his Majesty's Roman Catholic subjects,' forbids Jesuits, or members of other religious orders, communities, or societies of the Church of Rome, from coming into the realm, under pain of being banished from it for life; except natural born subjects, who were out of the country at the time of the passing of the Act. Such religious persons may, however, enter the United Kingdom on obtaining a license in writing from one of the principal secretaries of state, who is a Protestant, and may stay such time as such secretary shall permit, not exceeding six months, unless the license is revoked before the end of the six months. The Act also makes it a misdemeanour in any Jesuit, or member of other religious body, to admit, or to aid in or consent to the admission of, any person within the United Kingdom to be a member of such body; and any person admitted or becoming a Jesuit, or member of other such body within the United Kingdom, shall, upon conviction, be banished from the United Kingdom for life. It is, however, provided that nothing in this Act shall affect any religious order, community, or establishment, consisting of females bound by religious or monastic vows.

JESSULMIR. [RAJPOOTANA.]

JESUS, the CHRIST, the name usually given to the incarnate Son of God. Jesus was his proper name. It is the Greek form of the Hebrew name Joshua, a contraction of Jehoshua, that is, 'help of Jehovah,' or 'the Lord the Saviour.' The reason assigned by the angel for giving this name to the son of Mary was, 'because he shall save his people from their sins.' The word Christ is not a proper name, but an official title. It signifies 'anointed;' and is used in the New Testament as equivalent to Messiah, the name given to the long-promised Prophet and King whose advent was foretold by the prophets under the former dispensation. It is added to the proper name of our Lord to identify him with the promised Messiah, the deliverer 'of whom Moses in the law and the prophets did write: 'the Anointed One,' the consecrated Prophet, Priest, and King of the Church.

The 'fulness of time' which God had appointed for the sending of his Son arrived towards the close of the reign of Herod the Great, and Jesus was born at Bethlehem about the end of B.C. 5, or the early part of B.C. 4. He was the son of Mary, a virgin of the seed royal of David, to whom an angel was sent with the salutation, 'The Holy Ghost shall come upon thee, and the power of the Highest shall overshadow thee: therefore also that holy thing which shall be born of thee shall be called the Son of God' (Luke i. 35). Joseph, her betrothed husband, when he heard from her what had taken place, intended to put her away privately, but being convinced of her purity by a supernatural communication, he took her to be his wife. A general census of the Roman empire had been ordered by Augustus about this period, and therefore Joseph and Mary went from Nazareth, their usual residence, to Bethlehem, the city of David, to be taxed, and there the King of the Jews was born, in fulfilment of the prophecy of Micah v. 2, that out of Bethlehem Ephratah shall he come forth that is to be ruler in Israel.

Herod was much troubled at the miraculous cir-

cumstances which attended the birth of Jesus, and at the coincidence of the place of his birth with the prophecy of Micah. In order, therefore, that the danger to his authority might be obviated by the destruction of the infant sovereign, he gave orders that all the male children in Bethlehem and the neighbourhood under two years of age should be put to death. But Jesus was saved by his parents, who were warned by an angel in a dream to flee with the child into Egypt.

The child Jesus was circumcised in due time, and brought to the temple at Jerusalem, where his mother made the offering for her purification, as the law enjoined. Here the Saviour was recognized by Simeon, an aged disciple, and by Anna, a prophetess, who prophesied of his divine work: the former rejoicing that his eyes had seen the salvation of God, the latter speaking of him 'to all that looked for redemption in Jerusalem' (Luke ii. 28-38).

The divine mission of the Redeemer was not only recognized among the chosen race, but among the heathen also, for 'wise men from the east,' probably Persian magi of the Zend religion, guided miraculously by a star, came to Bethlehem, sought out the Saviour and worshipped him, and offered gifts of gold, frankincense, and myrrh.

After the death of Herod, in less than a year, Jesus returned with Joseph and Mary to Palestine, and went to Nazareth, where they took up their residence. The evangelists record none of the events of our Saviour's childhood, with the exception of his disputation with the Jewish rabbis. When he was twelve years of age he was found in the temple, hearing the doctors and asking them questions, 'and all that heard him were astonished at his understanding and answers.' This fact shows that Jesus was already aware of his divine mission, and was consciously preparing for it throughout his early life until the period for the actual commencement of his ministry arrived. When the time of his showing to Israel came he had reached his thirtieth year. Shortly before this period John the Baptist began to preach in the wilderness in the spirit and power of Elijah, and exhorted the people to repent, for the time was fulfilled and the kingdom of God was at hand. Great multitudes flocked to receive from him the baptism of repentance, and with the rest came Jesus to receive this rite at John's hands. As he came up out of the water the heaven was opened, the Spirit was seen descending upon him in a visible shape, and a voice was heard: 'This is my beloved Son, in whom I am well pleased.'

Immediately after this inauguration into office as the Messiah, Jesus passed through the ordeal of the temptation in the wilderness, and entered on his ministry. At Bethabara, to which he returned, he began to collect disciples round him: first Andrew, and another (probably John), then Simon Peter, and Philip, and Nathanael, though some time elapsed before they were formally set apart to the apostolic office. He then set out for Galilee, and at Cana, in that district, performed his first miracle by turning water into wine. He next repaired to Capernaum, and after a sojourn there of 'not many days,' he visited Jerusalem to keep the passover. According to John, the first expulsion of the money-changers and traders from the temple took place at this

passover, and so did the visit of Nicodemus, a member of the Sanhedrim (John iii. 1). After a sojourn in the capital of uncertain duration, Jesus went down to the Jordan with his disciples, and they there baptized in his name. He then proceeded to Galilee by the shortest route through Samaria; and while wearied and athirst he sat on the side of Jacob's well at Sichem, and in conversation with a woman who came to draw water from the well, he announced a change in the worship of both Jew and Samaritan, and avowed himself to be the Messiah. He then went on to Nazareth, his own city, where his exposition of a passage from Isaiah (lxi. 1) roused his fellow-townsmen to such fury, that they would have destroyed him if he had not escaped out of their hands. He took refuge in Capernaum, and wrought many miracles for the relief of the sick and of demoniacs. He then turned his thoughts to the rest of Galilee, where other 'lost sheep' were scattered, and made a general circuit of the whole province, in the course of which he wrought many works of mercy, and exhorted the Galileans to repent and believe the Gospel.

Jesus now entered on the second year of his ministry, and went up to Jerusalem to a feast of the Jews, probably the passover. The cure at the pool of Bethesda of the man who had an infirmity thirty-eight years was wrought during this visit on a Sabbath-day, and excited the lasting anger of the Jewish authorities, who sought to kill Jesus, both because he had healed a man on the Sabbath, and because he justified his 'doing well' on that day by an unequivocal claim to the divine nature. The indignation of the Pharisees was strengthened by the discussion which soon after took place respecting the disciples plucking the ears of corn and the healing of the man with a withered hand.

The ordination of the twelve apostles occurred about this period. They had previously associated themselves with Jesus, were his constant companions, and witnesses of the miracles by which the truth of his doctrines was demonstrated; but they were now organized into a distinct body under the name of Apostles, though they were not sent forth to preach until late in the same year. The solemn appointment of the chosen twelve was followed by the Sermon on the Mount, in which he proclaimed the laws and constitution of the kingdom of heaven, and who were meet to be its citizens. A second circuit of Galilee now commenced, in which the apostles journeyed with him; and mention is made of a third, which probably took place towards the close of this year, when he sent forth the twelve by themselves, two and two, to teach and to heal for him. Their mission, which lasted about two months, was limited to their own countrymen.

The third passover now drew near, but Jesus did not go up to it, because his ministry in Galilee was not completed, and his 'time was not yet come.' He went with his apostles to a mountain on the eastern shore of the sea of Tiberias, where he wrought one of his most remarkable miracles for the purpose of producing food for 5000 men, besides women and children. Several other miracles followed (Matt. xiv. 33; Mark vi. 53-56), and then a visit at Capernaum from the Scribes and Pharisees from Jerusalem (Matt. xv. 1). Leaving this neighbour-

hood, the Saviour next travelled to the north-west of Galilee to the regions of Tyre and Sidon, where he healed the daughter of a Syrophenician woman. Returning thence, he passed round by the north of the sea of Galilee to the region of Decapolis, on its eastern side; and among other miracles, fed 4000 persons with seven loaves. His ministry in Galilee was now drawing to a close. According to M. Renan, it had been eminently successful, and everywhere in Galilee he met with a cordial and enthusiastic reception. But the evangelists explicitly state that while here and there a few 'heard him gladly' and embraced his doctrines, the great mass listened to him with indifference and insensibility; and the awful denunciations which he uttered against the towns of Chorazin, Bethsaida, and Capernaum (Matt. xi. 23, 24) clearly imply a complete rejection of his ministry.

A memorable conversation with his disciples respecting self-denial, foreshadowing his own sufferings (Matt. xvi.), was followed by his Transfiguration on the holy mount. He then set out for Jerusalem, as the feast of tabernacles was approaching, taking the direct but less frequented route by Samaria, that his journey might be 'in secret.' On the way he sent out the seventy disciples, an event mentioned only by Luke (chap. x.). He came to Jerusalem 'about the middle of the feast,' and found the minds of the people strongly excited, and public opinion divided respecting his claims. The Pharisees and rulers sought to arrest him, but they feared the people. It is probable that Jesus returned to Galilee, and spent the interval between the feast of tabernacles and that of the dedication in journeying and instructing the people. The parables of the good Samaritan, the prodigal son, the rich man and Lazarus, &c., belong to this period; as also the account of Martha and Mary, and the miracle of the ten lepers. After the feast of dedication Jesus returned to Bethabara, beyond Jordan, where he heard of the illness of Lazarus, and, two days after, proceeding to Bethany, he performed the most signal of his miracles—the raising of his friend from the dead. The publicity and results of this miracle brought matters to a crisis with the Sanhedrim. A meeting was immediately called, and the matter fully discussed, and it was resolved that Jesus should be put to death. The anointing of the Saviour by Mary, the sister of Lazarus; his triumphal entry into Jerusalem; his lamentation over the city, whose destruction he foretold; his second expulsion of the crowd of traders from the temple; the treachery of Judas; the observance of the passover by the Master and his disciples, and the institution of the Lord's Supper; his dreadful agony in Gethsemane, and arrest by a band of soldiers led by the traitor; the trial of the Christ before the Sanhedrim on the charge of blasphemy, and his condemnation; the second trial before Pilate, the Roman procurator, on the charge of sedition, and his ultimate ratification of the sentence of death; the scourging, the blows, and insults of the soldiers; the procession to Calvary, and the crucifixion there of the King of the Jews between two thieves—all followed in rapid succession. On the third day Jesus rose from the grave, according to his own prediction. During forty days he appeared among his disciples, whom he instructed

more fully concerning the nature of his kingdom, and gave them their final commission. He then 'led them out as far as to Bethany, and while he blessed them he was parted from them, and carried up into heaven.'

The great body of Christians have from the earliest ages believed on the combined evidence of his miracles, instructions, and character, that Jesus is the Messiah predicted in the Old Testament Scriptures, the eternal Son of God, equal to the Father. Those who agree in rejecting this view hold widely different opinions among themselves respecting the person and work of Christ: from the high Arian theory that he was the greatest of created beings, down to that of modern infidelity, which regards him as a mere man, and by no means a perfect man. The latest teachers of this school, Strauss, Baur, Renan, and Newman, have now adopted substantially the same theory. Strauss, indeed, at first broached what is called the mythical view, that Jesus was simply a Jewish rabbi who lived in Judea about 1800 years ago, who shared in the feelings and hopes of his countrymen at that period, around whose life a vast number of legends and fables have in the course of time clustered; that after these had floated about in Christian society they were collected and put into shape about the middle of the second century by certain unknown writers, who had no personal knowledge of the transactions described. The notion that such a collection of legends could have been palmed on the world for truth in probably the most sceptical age the world has ever seen, was from the first seen to be absurd by all intelligent men, and has now been completely exploded. Even Strauss himself has been compelled to modify his original theory, and has now ascribed the miraculous events of the Saviour's life to wilful imposition. Renan, Baur, and Newman have adopted the same view, and have substituted for the myth of Strauss the notion of 'conscious design and of planning intuition.' They exonerate the apostles, however, from the reproach of designing untruthful narratives and of fabricating history, and direct their attacks against the person of Christ himself. They speak of the unbounded self-exaltation of Jesus, his deficiency in modesty, humility, and knowledge of self, his enthusiasm verging on insanity, and intolerable pride. M. Renan accuses the Saviour of using artifice and deception to impose on the people, of assuming a character to which he had no real claim, and of pretending to work miracles which are impossible; while at the same time he calls him a man of unparalleled greatness, speaks of his divine instinct and divine life, and says between him and God mankind will not any longer distinguish. The facts, however, of our Saviour's life are related by trustworthy and unprejudiced eye-witnesses, who could have no motive but a regard to truth to narrate events which were at variance with all their prepossessions and expectations, and who sealed their testimony with their blood. These statements were made public at a time when multitudes were alive who could have contradicted them if they had been untrue, and who had the strongest motives to do so; yet no such denial was ever given by the Pharisees and Scribes, and other hostile Jews. The events of our Lord's career being thus established by

the testimony of competent, credible, trustworthy, disinterested witnesses, it necessarily follows that his claims and doctrines are entitled to implicit belief.

The character of Christ, as delineated by the sacred writers, is perfectly harmonious throughout; all the actions and instructions ascribed to him are in strict unison with his personal qualities, as these are with each other. But the Christ of Renan and Baur is a moral monstrosity, a real impossibility, a combination of qualities which never have been, and we may venture confidently to affirm, never will be found in combination in the same person.

JESUS, son of Sirach, was a learned Jew of Jerusalem, who employed himself in collecting sayings of wise men, from which, with additions of his own, he formed the book of ECCLESIASTICUS. ('Ecclesiasticus,' i. 27.) We know little of him but what we can gather from that book, which was probably composed about 180 B.C.

JESUS COLLEGE, CAMBRIDGE, was founded in 1496, by John Alcock, bishop of Ely, who had obtained from King Henry VII. a grant of the nunnery of St. Radegund, then lately suppressed. It has sixteen foundation fellowships, open to natives of England and Wales, without any restriction or appropriation whatsoever. Six of the fellows are required to be in orders. On every vacancy of a fellowship, the master and fellows nominate two candidates, of whom the bishop of Ely elects one. To one of the fellowships, however, founded by James Stanley, bishop of Ely, the bishop has an exclusive right both to nominate and appoint. The mastership of this college is in the absolute appointment of the bishop of Ely. Various scholarships, exhibitions, and smaller foundations, of different annual values, have been bestowed on this college from time to time by different benefactors. The buildings consists of two courts situated in the eastern part of the town. One of the courts is small, very ancient, and surrounded by a cloister. (*Cambridge University Calendar*, 1866.)

JESUS COLLEGE, OXFORD, owes its foundation to the zeal of Hugh ap Rice, or Price, a native of Brecknock, who meditated the establishment of a college which should extend the benefits of learning to the natives of Wales. Queen Elizabeth, on his petition, granted a charter of foundation, dated June 27, 1571, the society to consist of a principal, eight fellows, and eight scholars. Lands were left by the founder, and the income of the college was so increased by different benefactors, that a few years since the society consisted of a principal, nineteen fellows, and eighteen scholars.

But by the recent ordinance of the University Commissioners, as vacancies occur, the fellowships will be reduced to thirteen, which are to be divided, as nearly as possible, into two moieties; one moiety to be termed Welsh fellowships, and to be filled up by natives of Wales or Monmouthshire, if any such be found of sufficient merit. For the other moiety, no person shall be either entitled to preference, or ineligible, by reason of his place of birth. The fellowship founded by King Charles I. for natives of Guernsey and Jersey, is to be applied to the maintenance of not less than two scholars, to be elected by the principal and fellows from persons born in one of the Channel Islands; or educated at Eliza-

beth College, Guernsey, or at Victoria College, Jersey.

One fellowship is devoted to the purposes of the professoriate of the University; and the emoluments of four other suppressed fellowships are to be applied to raise the number of the scholarships, other than King Charles I's, to twenty-two, and their income to 80*l.*, per annum. Of these, twenty are to be termed Welsh scholarships, and to be filled up by persons born in Wales or Monmouthshire; or educated for four years at one of the Free Grammar Schools of Abergavenny, Bangor, Beaumaris, Bottwinnog, and Cowbridge. Two continue to be open scholarships.

There are nearly thirty exhibitions of 40*l.* per annum, tenable for five years from matriculation. This was the first Protestant college, and in its statutes the Protestant religion is guarded by several enactments. (*Oxford University Calendar*, 1866.)

JET, a black bituminous mineral, found in many parts of the world. In France large quantities are procured from the department of Aude; in Spain, from the province of the Asturias; and in England, from Whitby, in Yorkshire. It is a kind of pitch-coal, capable of being cut, and of receiving a fine polish. In Prussia, it is called black amber. It is chiefly used for making mourning ornaments, such as bracelets, brooches, beads, &c.; also, for rosaries, crosses, and other trinkets.

JETHOU. [GUERNSEY.]

JETSAM. [FLOTSAM.]

JEWELLERY. This term comprises the setting of precious stones, and also the manufacture of small ornamental works in gold and silver. It is probable that the wearing of gold and silver ornaments is almost as early as the discovery of those metals. The jewels found in Egyptian tombs bear the stamp of artistic production, and have been rarely surpassed even in modern days.

There are great differences in the quality of the gold used by modern jewellers. Old standard gold used to have, and sterling gold still has, 22 parts of gold to 2 of alloy; new standard has 18 to 6. [HALL MARK.] The so-called fine gold of the jewellers is now usually about 16 carats. Some jewellers' gold is as low as 3 carats, not worth more than about 9*s.* per ounce. Silver, copper, and zinc are used for alloy. There are many compositions and many imitations of gold used by artificers.

The different kinds of jewellery imported into the United Kingdom in 1864—chiefly from Hamburg, Belgium, and France—were valued at 97,099*l.* The exports in the same year were valued at 180,399*l.*, the largest quantities being sent to India, the Channel Islands, and North America.

JEWS, a term, in its widest acceptance, used as synonymous with Hebrews, or Israelites, but in a more restricted sense applied to the inhabitants of the kingdom of Judea as it existed in the time of Jesus Christ, and whose descendants are now scattered over the world. Their ancestor Abraham, called 'the Hebrew,' by birth a Chaldean, emigrated, about 1921 B.C., with his wife Sarah, his nephew Lot, and his servants and flocks, to the land of Canaan, the modern Palestine, where he settled. [ABRAHAM.] At an advanced age his wife bore him a son, Isaac, from whom the Hebrews are descended. Abraham's

elder son Ishmael, whose mother was an Egyptian and a slave, settled in the wilderness of Arabia. Isaac married Rebecca, by whom he had two sons, Esau and Jacob, the former of whom was a hunter, and gave up his birthright to his younger brother Jacob. Jacob, surnamed Israel, or 'the strong' (Genesis xxxii. 28), had twelve sons, namely, Reuben, Simeon, Levi, Judah, Dan, Naphtali, Gad, Asher, Issachar, Zabulon, Joseph, and Benjamin. From these were descended the twelve tribes of Israel, or of the Hebrew nation.

One tribe, the descendants of Levi, was set apart for religious service. Out of this class the officiating priesthood was chosen, as well as the scribes and keepers of records, the judges, and perhaps also the physicians.

The history of this people previous to the time of Christ is contained in the Old Testament and in Josephus.

To the Asmonæan dynasty [ASMONÆANS] succeeded that founded by Herod the Great [HEROD], under whom Christ was born. These kings, dependent on Rome for support, were in fact no more than Roman lieutenants. Under Herod Agrippa a succession of more than usually rapacious Roman governors, Felix, Albinus, and Florus, drove the people into insurrection, and led the way to an open revolt against the Romans. A party called the Zelotes, or fanatics, now obtained an ascendancy over the minds of the people, and the feeble Roman garrison was overpowered and massacred. At the same time the Greeks of Cæsarea put to death all the Jews in that city, but the Roman governor Florus took no notice of the transaction. Other cities of Palestine and Syria followed the example of Cæsarea by a wholesale butchery of the Jews. The Jews retaliated in those towns of Palestine where they were the majority by murdering the Syrians and Greeks. The Romans advanced against Jerusalem, and were repulsed; but Vespasian, an officer of tried abilities, was sent by the Emperor Nero into Syria, A.D. 66–7. Vespasian assembled his forces at Ptolemais, where he was joined by Agrippa and by his own son Titus. His army, including auxiliaries, amounted to 60,000 men. For one year he employed himself in scouring the country and reducing the strongholds of the Jews. In the following year, A.D. 68, Nero's death gave them a respite of nearly two years, during which, however, the inhabitants destroyed each other through intestine factions. At last Vespasian was proclaimed emperor; and Vitellius being defeated, he entered Rome. His son Titus was left behind to complete the subjugation of Jerusalem. The regular siege began in the spring of A.D. 70, and it lasted till the following September, when the Holy City was finally taken and totally destroyed, with its temple: the inhabitants were killed or sold for slaves. Still the Jewish population was by no means extirpated from the country, and we find them rising in vast numbers in the reign of Hadrian, and again engaging the Roman legions commanded by Severus. They were, however, overpowered with immense slaughter, and the second desolation of Judea took place. [BARCOCHEBAS; HADRIAN.]

The dispersion of the Jews over the world, which is commonly dated from the destruction of Jerusalem, had in reality begun long before. The Ptolemies

had transplanted large colonies of them into Egypt, Cyrene, and Cyprus; and Antiochus the Great settled great numbers in the towns of Asia. In the time of Cicero ('Pro Flacco') there was a wealthy Jewish community in Italy. A passage of Philo, in his letter to Agrippa, enumerates the countries in which the Jews were settled in the time of Caligula: Egypt, Syria, Pamphylia, Cilicia, the greatest part of Asia Minor as far as Bithynia, the shores of the Euxine, Macedonia, Thessaly, Ætolia, Attica, the Peloponnesus, Cyprus, and Crete, besides the countries beyond the Euphrates. Alternately persecuted and protected by the emperors, both of the west and of the east, they acquired by their commercial industry wealth and importance when unmolested, and their numbers saved them from annihilation when in disfavour. But the rise of Mohammedanism brought an unfavourable change to the eastern Jews. Mohammed endeavoured at first to win them over, but they refused to acknowledge a descendant of Hagar the bondwoman as the greatest of prophets; and Mohammed treated them without mercy in Arabia, where they were at that time numerous. But under the caliphs, his successors, they were protected on the easy terms of paying tribute; and as they made no resistance, they experienced not only protection, but even encouragement from their new masters, whom they followed through their tide of conquest along the coast of northern Africa. They also contributed materially to the triumph of the Crescent in Spain, where the Jews had really a golden age, which lasted for some centuries. There they cultivated science and literature; and the names of Benjamin of Tudela, Isaac of Cordova, Hasdai, the confidant of Abderrahman, and many others, are examples of their proficiency. At the same time they were thriving in the East under the caliphs of Bagdad, whose favour they enjoyed, at least till towards the end of the tenth century.

Charlemagne protected the Jews like his other subjects: they filled municipal offices; they were physicians and bankers. The Jews enjoyed the same, or even greater influence under Louis le Debonnaire and Charles the Bald, but towards the end of the latter reign the clergy began afresh to show their hostility. Philip Augustus, pressed by the wants of an empty exchequer, and perhaps also by the reports of fanatics, who charged the Jews with all sorts of crimes, banished, in 1180, all the Jews from his dominions, confiscated their property, and declared all debts due to them to be annulled. About twenty years afterwards the Jews were readmitted, but were again expelled under Charles VI.

In Italy the Jews seem to have enjoyed great though not uninterrupted security; but their safest asylum was Poland, where Casimir the Great allowed them considerable privileges, and where they formed the only middle order between the nobles and the serfs. It was in Spain and Portugal, after the expulsion of the Moors, that the proscription of the Jews was most sweeping and effectual. The number of Jews expelled from Spain has been vaguely estimated at 500,000, and even 800,000. The expulsion of the Jews, and that of the Moors or Moriscos, drained Spain of its most useful subjects.

Throughout the dominions of the Sultan the Jews were allowed to settle and follow their trades, though

looked upon with scorn by the Osmanlees. In the regencies of Barbary they settled likewise in great numbers.

During the eighteenth century a milder spirit of toleration manifested itself toward the Jews in several countries of Europe. Maria Theresa and Joseph I. gave them equal rights, and subjected them to the same laws with the Christians. Frederick, called the Great, was not so liberal towards them, for he laid them under peculiar restrictions and disqualifications. In Holland they have long formed a highly flourishing, numerous, honourable, and intelligent community. Napoleon, in 1806, issued an ordinance giving them a regular organization throughout France, and placing them on the same footing as other Frenchmen. This system has remained unaltered. The king of Prussia and other German powers have followed the example. In Russia the Jews are subject to many restrictions, and especially the Rabbins. In the United States of North America they are placed on the same footing as other citizens.

It does not appear at what time the Jews found their way to this island, but they were settled here in the Saxon period, and as early as 750. From the time of the Conquest they rapidly increased in number. In the reign of Edward I., about 1290, all the Jews were banished from the kingdom. Their numbers at that time are conjectured to have been between 15,000 and 16,000. It was not till after the Restoration, in 1660, that they again settled in England. In the year 1753 an Act was passed to enable foreign Jews to be naturalized without taking the sacrament; but the Act was repealed in the following session, under the influence of the popular feeling, which was most strongly opposed to the measure.

During their residence in England, up to their banishment in the time of Edward I., the Jews were considered as the villeins and bondsmen of the king. The statute of the 54th and 55th of Henry III., which declared the Jews incapable of purchasing or taking a freehold interest in land, &c., and the Statutum de Judaismo, 3 Edward I., which forbade Jews from alienating in fee, either to Jew or Christian, any houses, rents, or tenements which they then had, or disposing of them in any way without the king's consent, &c., were repealed by the 9 and 10 Vict., c. 59. By the Reform Act of 1832 they were admitted to the elective franchise, and in 1845 the 8 and 9 Vict., c. 59, was passed, by which they were made eligible to fill all municipal offices. In the following year their marriages were legalized, and in 1855 their places of worship were placed on the same footing as those of Roman Catholics and Protestant dissenters. In 1858 they were admitted to Parliament, by the omission from the usual oath of the words, 'on the true faith of a Christian,' in any case where the person elected shall declare himself a Jew. They are now, therefore, in exactly the same position, and enjoy precisely the same privileges, as other subjects of her majesty.

According to a calculation recently made, there exist in the whole world nearly 7,000,000 of Jews, of whom one-half are in Europe, especially in Russia, where there are 1,220,000. The number in Austria is 853,000; in Prussia 284,500; and in the rest of Germany, 492,000. At Frankfort-on-the-Maine

there is one Jew to sixteen Christians; in Sweden and Norway only one in 600. France contains 80,000, England 42,000, and Switzerland 3200. A remarkable fact is that in the countries where the Jews are completely emancipated their number is diminishing, while elsewhere it is increasing. Since the commencement of the present century the societies for the conversion of the Jews (thirty-three in number, and employing 200 missionaries), have at the most, and with great expense, made but 20,000 proselytes.

Of the 40,000 Jews in England about 20,000 are in London. They have in England and Wales about sixty synagogues, with accommodation for about 10,000 worshippers. In Scotland and Ireland their numbers are very few indeed, but they are more numerous in the British colonies and the United States. In scarcely any country in the world is there now any active persecution against them or their faith.

JHILUM. [HINDUSTAN.]

JIB, a triangular sail placed in front of the foremast in all vessels, in small ones having the bowsprit for a base, in large ones the jib-boom. The flying-jib, or extra front sail, has the flying jib-boom for its base. The *jib-boom* is an extension of the bowsprit, and a flying jib-boom runs out beyond this, thus giving a greater spread for the jib-sails.

JIDDA. [ARABIA.]

JOA'CHIMITES, a sect of heretical Christians of the thirteenth century, founded by Joachim, abbot of Flora, in Calabria, who was esteemed a great prophet while he lived, and left behind him several books of prophecy. Their tenets were formally condemned by the councils of Lateran and Arles in 1215 and 1260.

JOAN, POPE, a supposed individual of the female sex, who is placed by several chroniclers in the series of popes between Leo IV. and Benedict III., about 853-55. David Blondel, a Protestant, completely refutes the story in his '*Familière Eclaircissement de la Question si une Femme a été assise au Siège Papal entre Leon IV. et Benoit III.*' Amsterdam, 1649.

JOAN or JOANNA I. of Naples, daughter of King Robert of Naples, of the Anjou dynasty, succeeded her father in 1343. She was then only sixteen years of age, but had been married some time to her cousin Andreas of Hungary. Andreas claimed to be crowned king, and to share his wife's authority. A conspiracy was formed by some of the barons, and Andreas was strangled. There seems little or no doubt that Joan knew of the plot; but nevertheless, by her orders, torture was employed to find out the conspirators, and many persons were put to a cruel death. The same year Joan married her relative Louis, prince of Tarentum. Louis, king of Hungary, and brother of Andreas, came with an army to avenge his brother's death, but Joan having been acquitted of the murder by Pope Clement VI., of whom she had demanded a trial, and a pestilence breaking out in Naples, the Hungarians withdrew, and Joan reigned many years in peace. Having lost her second husband in 1362, she married a prince of Majorca, and on his death she married, in 1376, Otho, duke of Brunswick. Soon afterwards the schism between Urban VI. and Clement VII. broke out, and Joan took part with the latter. Urban excommunicated her, and gave the investiture of the kingdom to her niece's husband,

Charles Durazzo, who revolted against his sovereign and benefactress, and took her prisoner. He tried to induce Joan to abdicate in his favour, but she firmly refused, and named as her successor Louis of Anjou, brother of Charles V., king of France. Charles then transferred Joan to the castle of Muro, in Basilicate, where he caused her to be strangled or smothered in her prison in 1382.

JOAN OF ARC. [ARC, JOAN OF.]

JOANES, or JUANES, VICENTE, a Spanish painter, was born at Fuente la Higuera in Valencia, in 1523. He studied in Italy, and chiefly the works of the Roman school. He died December 21, 1579, whilst engaged in finishing the altar-piece of the church of Bocairente. His best works are in the cathedral of Valencia, and there are several good specimens at Madrid.

JOANNINA, or JANINA, the capital of the Turkish province of Albania, and the residence of a pasha, is situated on the south-western shore of the Lake of Janina, in 39° 47' N. lat., 20° 53' E. long., and has about 25,000 inhabitants. It is supposed to stand on or near the site of the ancient Dodona. The city was taken in 1082 by the Normans, who under Bohemond, son of Robert Guiscard, defeated the Emperor Alexander Comnenus under its walls. In 1432 it fell into the hands of the Turks. An unsuccessful attempt made by the Albanian Greeks in 1611, to shake off the Turkish yoke, led to their expulsion from the old or fortified part of the town, and to the extension of the city along the shores of the lake on each side of the fortress. Janina was the capital of the famous Ali Pasha [ALI PASHA], under whom it contained 40,000 inhabitants, including the garrison, sixteen mosques, eight Greek churches, the seraglio and palaces of the pasha, the fortress mentioned above, and two others named Coulia and Litaritza. When Ali found himself no longer able to defend his capital against the Turks, he ordered it to be set on fire. So great was the destruction that followed, that although some of the houses have been rebuilt, the city has still a deserted and ruined appearance. The house situated on the small island opposite to the peninsula on which the fortress stands still bears marks of the violence used in the murder of Ali. A British consular agent resides in Janina, and there are extensive manufactures of gold brocade by Greek workmen, as well as gold lace for the East, and morocco leather, silk goods, and coloured linen. There are several mosques and Greek churches in the town. Janina stands in the midst of an extensive and fertile plain which produces fruits and grain in abundance.

JOB, *the Book of*, is one of the poetical books of the Old Testament. Its title is taken from the patriarch Job, whose story it relates. Some critics have supposed, from the nature of the exordium, that Job was not a real person, and that the narrative in the book is fictitious. He appears, however, to be referred to as a real person by Ezekiel (xiv. 16), and James (v. 11); and the style of the book has all the circumstantiality of a real narrative. It has been inferred, from his longevity (xlii. 16), his holding the office of priest in his own family (i. 5), his allusion to no other species of idolatry than the worship of the heavenly bodies (xxxi. 26-28), the

silence of the book respecting the history of the Israelites and the Mosaic laws, and several incidental allusions to patriarchal customs, that Job lived in the patriarchal age. The scene of the poem is laid in the 'land of Uz,' which, as Bishop Lowth has shown, is probably Idumæa. The language is Hebrew, with a considerable admixture of Arabic, or, as others contend, of Aramaic. The author is unknown, but is supposed to have been contemporary with Abraham. The canonical authority of the Book of Job is fully established by frequent quotations from it, both in the Old and New Testament.

JOHN, king of England, surnamed Sansterre, or Lackland, was the youngest son of Henry II., and was born at Oxford, December 24, 1166. John married the youngest daughter of William, earl of Gloucester. In 1178 his father conferred upon him the dignity of Lord of Ireland; and in 1185 John went to take the government into his own hands; but the insolent demeanour of the prince and his attendants so disgusted the Irish, that his father found it necessary to recall him in the following December.

No opposition was offered by John to the accession of Richard, notwithstanding his own ambitious expectations; but when the intelligence of his brother's captivity arrived in 1193, John at once openly took steps for the usurpation of the throne. In this attempt, however, he was successfully resisted; and on the return of Richard to England, in March, 1194, John's castles and estates were seized by the Crown, and he fled to Normandy, whither he was followed by the king at the head of an army; but the traitor made his peace by an abject submission. It is said that Richard, when on his death-bed, was induced to declare John his successor.

John was present when Richard expired at Chalus, 6th April, 1199, and before visiting England he hastened to secure the submission of the various continental territories of the Crown. Meanwhile in England, by the activity of the justiciary Fitz-Peter, a unanimous resolution to receive him as king had been obtained from a great council held at Northampton. Soon after this, John made his appearance in person; and he was crowned at Westminster, on the 26th of May, the festival of the Ascension.

Philip Augustus of France having, for his own purposes, espoused the cause of Arthur (the son of Richard's elder brother Geoffrey), whom he had got into his possession, soon overran both Normandy and Anjou; but in May, 1200, John purchased a peace. The next year John procured a divorce from his wife on the plea of consanguinity, and married Isabella, daughter of Aynar, count of Angoulême, who had already been betrothed, and even privately espoused, to Hugh, count of La Marche. The complaints of the count gave Philip such a pretence as he wanted for renewing the war; and again putting Arthur forward as the legitimate lord of the old fiefs of the Plantagenets, he rapidly obtained possession of all the most important towns and places of strength in those countries. Arthur, however, was taken captive by his uncle (August 1, 1202), immediately consigned to close custody in the castle of Falaise, whence he was removed to Rouen, and was universally believed to have been there put out

of existence by his uncle's order. Notwithstanding the capture of Arthur, however, the war in France went wholly against John: and before the end of the year 1204, Normandy, Anjou, Maine, and Touraine were rent from the crown of England, and reannexed to that of France. Two years afterwards John made an unsuccessful attempt to recover what he had thus lost.

While still at war with France, John became involved in another contest at home. By insisting upon the right of the crown to nominate the archbishop of Canterbury, he drew upon himself the hostility of the whole body of the national clergy, and also of the Pope [INNOCENT III.], at whose instigation Philip Augustus prepared to invade England.

The ill success of an expedition against France induced John to make the most humiliating submissions to the Pope, to whom he surrendered his kingdom and paid homage and tribute. Philip, mortified by this pacification, would have persisted in his project of invasion but for the result of a battle fought in June, 1213, between the English and French fleets, in the harbour of Damme, the first great victory in the naval annals of England, in which 300 of his vessels were captured, about 100 burned, and all Philip's military stores and provisions taken or destroyed. On the 19th October, 1214, a truce was arranged between the two kingdoms, to last for five years. But the depressed state of John's affairs now presented to his barons an opportunity for the renewal of demands which they had repeatedly made in vain. The result was the celebrated meeting on the plain of Runnimede, on Trinity Monday, June 9th, 1215, and the concession and signature of the Great Charter. [MAGNA CHARTA.] This was followed by fresh encounters with the barons, caused by John's endeavours to escape from the obligations of the charter, which the Pope annulled at his request, excommunicating the barons and laying London under an interdict. John contrived to triumph not only over these adversaries, but also to defeat the king of Scotland, who had taken the opportunity to invade the kingdom. The barons, as a last resource, invited Louis the dauphin to accept the crown. Louis set sail from Calais with a fleet of six hundred and eighty sail, and on May 30, 1216, landed at Sandwich, attacked and reduced the castle of Rochester, and immediately marched to the capital. The contest which followed seemed of doubtful issue; but on October 14th, as John was attempting to ford the Wash at low-water, from Cross-keys to the Fossdyke, and had already got across himself with the greater part of his army, the return of the tide suddenly swept away the carriages and horses that conveyed all his baggage and treasures; on which, in an agony of vexation, he proceeded to the Cistercian convent of Swineshead, and was that same night seized with a violent fever, which was attributed to poison. He was conveyed the next day in a litter to the castle of Sleaford, and thence to the castle of Newark, where he expired, October 18th, in the forty-ninth year of his age, and the seventeenth of his reign. He was succeeded by his son Henry. [HENRY III.]

JOHN I.—XXIII. [POPE.]

JOHN OF GAUNT. [EDWARD III.]

JOHN OF SALISBURY finds a place in every catalogue of learned Englishmen. His era was the reign of King Henry II. John had studied at Oxford, but he visited also the universities of France and Italy. He became bishop of Chartres in 1164, and died in 1182. His principal historical writings were lives of two archbishops of Canterbury, Anselm and Thomas à Becket. But the work by which he is best known to scholars is entitled 'Polycraticus, sive de Nugis Curialium et Vestigiis Philosophorum,' in which he describes the manners of the great, speaking not unfrequently in a style of sharp satire. His other works are of inferior interest.

JOHN O'GROAT'S HOUSE, Scotland, in the county of Caithness, a mile and a half west from Duncansby Head, is a site once occupied by a cottage, and proverbially nearly the most northern point of Great Britain. According to tradition the name is a corruption of John de Groot, a Dutchman, who settled at the spot about the reign of James IV., and arranged a dispute among his eight sons upon a point of precedence, by making eight doors to his dwelling, by which means they passed in and out without quarrel. Whatever may be the value of the tradition, there can be no doubt as to the existence of a John Groot, for in 1496, 'John Groot, son of Hugh Groot,' had a grant of a penny land in Duncansby, from William, earl of Caithness. The family still exists.

JOHN, SAINT, *the Baptist*, son of Zachariah, a Jewish priest, and Elizabeth, his wife, who was a near relation of Mary, the mother of Jesus Christ, was born to them in their old age. The sacred office was assigned to him of being the precursor or herald of the Messiah. With the acts of John the Baptist begins the public ministry of Jesus Christ, who at his baptism was announced, both by the Baptist himself and by a voice from heaven, to be the Son of God, the Messiah.

From this time we hear little more of John till we find him in prison. He had ventured publicly to reprove Herod the king for an act of great immorality. Herod had married Herodias, who was the wife of Philip, tetrarch of Idumæa, his own brother. The Baptist's reproof was resented more violently by Herodias than by Herod, and at her instigation John was beheaded.

JOHN, SAINT, *the Apostle and Evangelist*. James and John, the sons of Zebedee, were both admitted by our Saviour into the number of his Twelve Apostles, and John was throughout distinguished by him with peculiar marks of regard, as we find in all the Gospels.

After the resurrection of Jesus he was again distinguished by his notice; and when Jesus had ascended to heaven, and the interests of the gospel were committed especially to those who had been chosen by him out of the world, John became one of the leading persons in the church.

Saint John's labours in the church were chiefly among the inhabitants of Syria and Asia Minor, and no doubt he had a large share in planting Christianity in those provinces, where for a time it flourished greatly. We have no particulars of his labours on which we can safely rely; but there is little reason to doubt that he was at one period of his life banished to the island of Patmos, and that

there he wrote the book called the 'Apocalypse,' or 'Revelation.'

There are also preserved three of his epistles; but the most valuable of his writings which have descended to our time is his Gospel.

JOHN, ST., OF JERUSALEM, KNIGHTS OF. [MALTA, KNIGHTS OF.]

JOHN, ST., River. [CANADA.]

JOHN'S COLLEGE, ST., CAMBRIDGE, was projected and begun by Margaret, countess of Richmond, a short time before her death, which happened in 1509. It was completed by her executors, under the authority of a papal bull and the royal mandates of her son and grandson, King Henry VII. and King Henry VIII., which gave them the power of suppressing a decayed hospital dedicated to St. John, at that time existing on the same site. The college, then consisting only of the present first court, was four years in building. The original endowment was for fifty fellows, but part of the foundation-estates having been seized by King Henry VIII., the funds were found to be sufficient for thirty-two only. The college now consists of a master, fifty-six fellows, and sixty foundation scholars, the fellowships and scholarships being open to all British subjects without any restriction or appropriation. There are also studentships in divinity and law, and several exhibitions and annual prizes.

The present buildings consist of the first court, a second court of large dimensions, and a third which contains the library. A handsome new court, built by Rickman on the opposite side of the river Cam, is connected with the old buildings by a bridge. (*Cambridge University Calendar*, 1866.)

JOHN'S COLLEGE, ST., OXFORD, was founded in 1555 by Sir Thomas White, Knt., alderman of London. The original foundation consisted of a president, fifty fellows and scholars, one chaplain, an organist, six singing men, eight choristers, and two sextons.

Under a recent ordinance of the university commissioners, amended by a committee of the privy council, the foundation is hereafter to consist of eighteen open fellowships tenable for life, five open scholarships and twenty-eight appropriated scholarships tenable for seven or five years, by persons elected from Merchant Taylors' School who shall not have attained the age of nineteen, and from the other schools who shall not have attained the age of twenty at the time of their election, viz., twenty-one to Merchant Taylors' School, two to Coventry, two to Bristol, two to Reading, and one to Tunbridge. There is also one open scholarship, called the Holmes scholarship, tenable for four years, without limitation in regard to age.

In 1854, four fellowships were established in this college in pursuance of the will of Dudley Fereday, Esq., of Ettingshall Park, Staffordshire. They are open, with certain limitations and under certain conditions in respect of literary proficiency, first, to the kindred of the founder; secondly, to natives of Staffordshire; and in case of a founder's kin or Staffordshire candidate not satisfying the conditions, then to any other person whatsoever, being a member of the Church of England. The tenure of the fellowships is for fourteen years.

The buildings of St. John's College form chiefly

two quadrangles, of which the first was originally St. Bernard's College, founded in the time of Henry VI. King Henry VIII. had granted these premises to Christ Church, Oxford, from which college Sir Thomas White purchased them in 1555. The second quadrangle was entirely built at the expense of Archbishop Laud. It was begun in 1631, and completed in 1635, from a design furnished by Inigo Jones. (*Oxford University Calendar*, 1866.)

JOHN'S, ST. [NEWFOUNDLAND.]

JOHN'S, ST. [NEW BRUNSWICK.]

JOHNSON, SAMUEL, the son of Michael Johnson, a bookseller at Lichfield, was born at Lichfield, September 18, 1709. As a child he was afflicted with the king's evil, which disfigured his face and impaired his eyesight. His education was commenced at Lichfield, whence he was removed to a school at Stourbridge; and in 1728, two years after he had left Stourbridge, he was placed at Pembroke College, Oxford. His father was unable to continue to maintain him at college, and he was compelled to return home without having taken a degree. In the December following (1731) his father died in such pecuniary distress, that Johnson was soon afterwards glad to become usher of a school at Market Bosworth, in Leicestershire; but finding the drudgery of this employment intolerable, he procured temporary employment in translating for a bookseller in Birmingham. During his residence in this town he became intimate with the family of a mercer named Porter, whose widow he subsequently married (1736). Mrs. Porter was more than twenty years older than himself, but he was much attached to her, and she added to other powers of increasing his happiness the possession of 800*l*. With this capital he established a school; but the scheme failed, and he left Staffordshire with his pupil Garrick to seek his fortune in the metropolis. He was employed by Cave the bookseller, the projector of the *Gentleman's Magazine*. In 1738 he published his 'London,' an imitation of the third satire of Juvenal, for which Mr. Dodsley gave him ten guineas, and by which he obtained a certain degree of reputation. His pen was continually at work, and his pamphlets, prefaces, epitaphs, essays, and biographical memoirs were continually published by Cave, either by themselves or in the *Gentleman's Magazine*, for which periodical in 1740, and for more than two years afterwards, he wrote the parliamentary debates. In 1744 he published his 'Life of Savage,' in the following year some observations on Shakspeare, of whose plays he afterwards published an edition. In 1747 he commenced his 'English Dictionary,' which he engaged to complete in three years for 1757*l*. In 1749 appeared 'The Vanity of Human Wishes,' an imitation of the tenth satire of Juvenal; and in the following year was printed the first paper of the 'Rambler.' On the death of his wife in 1752, he relinquished the 'Rambler.' The 'Dictionary' was published in 1755, in 2 vols. folio. In May, 1762, George III., through his minister Lord Bute, granted Johnson a pension of 300*l*. a year, and the days of his penury were at an end. He was introduced in the following year to his biographer Boswell, and we have from this date (1763) as full and minute an account of him as has ever been written of any individual.

In 1765 the University of Dublin sent over a

diploma creating him a doctor of laws; but he did not assume the title until some years afterwards, when the University of Oxford conferred a similar honour upon him.

In 1766 his friend Mr. Thrale received him into his house at Streatham. In the autumn of 1773 he made a tour, in company with Mr. Boswell, to the Western Islands of Scotland, of which he published an account. Two years afterwards he made a short excursion to Paris. The last of his literary labours was 'The Lives of the Poets,' 4 vols. 8vo., 1781. He died December, 1784, at his house in Bolt Court, Fleet Street. He was buried in Westminster Abbey, near the foot of Shakspeare's monument, and close to the grave of Garrick.

Boswell's 'Life of Samuel Johnson, LL.D.,' was published in 1791, 2 vols. 4to. Many editions have been since published. Boswell's life, of which there are numerous editions, still remains the principal authority. Some interesting details respecting the great lexicographer will be found in Hayward's edition of the 'Letters of Mrs. Thrale-Piozzi.'

JOHNSTON, GEORGE, an eminent Scottish naturalist, was born at Simprin in Berwickshire, on the 20th July, 1797, and died on the 30th July, 1855, at the age of fifty-eight. He was sent to school at Kelso, and then to Berwick. He afterwards went to the high school of Edinburgh, and he commenced his medical studies in that city about 1812, as an apprentice of the late Dr. Abercrombie. He passed as surgeon, and then went to London. He commenced practice at Belford. Subsequently he took the degree of M.D. at the University of Edinburgh, and became a fellow of the Royal College of Surgeons. He then settled as a medical man in Berwick, where he remained till his death. While he was a successful and celebrated medical man, he was also distinguished as a naturalist, and he lost no opportunity of cultivating science. He was an able zoologist and botanist. He published a 'Flora of Berwick-upon-Tweed;' 'The Botany of the Eastern Borders;' 'History of British Zoophytes,' and of 'British Sponges;' and he contributed various papers to *Loudon's Magazine*, and to the *Magazine and Annals of Botany and Zoology*, now continued under the name of *Annals of Natural History*. He was one of the editors of the last-named journal. He had a happy geniality of mind, and a kindness of disposition which endeared him to all. Wherever he went he gained friends, and he was universally beloved. He was the founder and first president of the Berwickshire Naturalists' Club, which has published valuable Proceedings. He was three times elected mayor of Berwick, and twice served the office of sheriff.

JOIGNY. [YONNE.]

JOINERY (French, *Menuiserie*) is the art of joining pieces of wood together for the interior fittings of buildings, for making articles of furniture, and for numerous purposes requiring greater neatness of workmanship than the operations of the carpenter. As carpentry and joinery are in many cases carried on in the same establishment, and even by the same workmen, it would be difficult accurately to define the limits of these two kindred trades. The proper object of carpenter's work in a building is to give firmness and stability to the structure; and within

its proper range may be embraced all the rough timber-work necessary for the support, division, or connection of the several parts of a building. Carpentry thus includes the construction of the framing of floors, partitions, and roofs. Joinery has for its object the addition of all the fixed wood-work necessary for convenience or ornament. Cabinet-making, or that department of wood-work which relates to the making of furniture, has little affinity with joinery, although the same materials and tools are employed in both descriptions of work. The line of demarcation, however, between joinery and cabinet-making seems to be even more difficult to define than that between carpentry and joinery; and, with the exception of such matter as veneering and polishing, which relate only to the use of the harder and more valuable woods, the operations of the cabinet-maker and the joiner are nearly identical, the same means being adopted by both for the production of neat and strong joints, and for evading the injurious effects of shrinkage and warping in the material operated upon. See Plate for illustration of details connected with this subject.

JOINT. [ARTICULATION.]

JOINT-STOCK BANKS. All banks which have more than six partners are called Joint-stock Banks, and were first allowed by 7 Geo. IV., c. 56, passed in 1826. The operations of the Bank of England are controlled by the 7 & 8 Vict., c. 32. [BANK.]

Private Banks.—By the 7 & 8 Vict., c. 98, no new bank of issue can henceforth be established in England, and only those bankers are now allowed to issue notes who were issuers on the 6th of May, 1844. The Act contains other regulations as to private banks of issue, and requires among other things a weekly return to the commissioners of stamps.

Joint-Stock Banks.—Nearly twenty years elapsed from the date of the Act which allowed the establishment of joint-stock banks, before a comprehensive Act was passed 'to regulate joint-stock banks in England.' This is the Act 7 & 8 Vict., c. 113, which received the royal assent on the 5th of September, 1844. On the same day, another Act (7 & 8 Vict., c. 111) received the royal assent, entitled 'An Act for facilitating the winding up the affairs of Joint-stock Companies unable to meet their pecuniary engagements;' and s. 48 of 7 & 8 Vict., c. 113, enacts that every banking company of more than six members in England shall be deemed a trading company within the provisions of this Act.

By sec. 47 of this Act every company of more than six persons, carrying on the business of bankers, is required to present a petition to her majesty in council, signed by at least seven shareholders, praying for a grant of letters patent; and this petition must set forth certain matters which are required by the Act. When joint-stock banks were first established, each shareholder was answerable to the extent of his whole property. By 1 Vict., c. 73, they were rendered liable only to the extent of their shares; but the liability did not extend to the shareholders as a body. By 7 & 8 Vict., c. 113, s. 47, the liability of any shareholder extends equally to the whole body of shareholders as a company; but if execution upon any judgment against the company shall be ineffectual to obtain satisfaction, then any shareholder may be proceeded against. These Acts have been repealed

by the Act noticed in the next article [JOINT-STOCK COMPANY], but the same Act re-enacted the 47th sec. of 7 & 8 Vict., c. 113, and also re-enacted sec. 12 of 20 & 21 Vict., c. 49, which made it lawful for ten persons, instead of the limit of seven, to form a banking partnership.

JOINT-STOCK COMPANY. Joint-stock companies are such companies as are unincorporated, and which trade upon a joint stock. All trading associations, however numerous, and although not established by charter or Act of Parliament, are legal, provided their purposes be legal, and provided they do not attempt to exercise the privileges of a corporation, such as the power of making their shares transferable at the will of the holder. The partners in joint-stock companies are of two classes: one consists of directors, trustees, and others, who are actively employed in conducting the concern; the other, of a number of persons who take little or no part in its management, and many of whom become shareholders for the sake only of a profitable investment of their money. The general conduct of the trade falls upon the directors, while the more particular transactions are usually managed by paid agents who are not shareholders. The funds and other property of the company are vested in the trustees.

Formerly the shareholders in a company were liable personally to all the debts of the company after its assets were exhausted; and the first attempt at limiting the liability of shareholders was made by 21 & 22 Vict., c. 91. Several acts were passed, but it was found that continual questions of liability rose under them, and the legislature determined by one comprehensive measure to settle the law of limited liability.

By the 25 & 26 Vict., c. 89, or 'The Companies' Act, 1862,' the laws relating to the incorporation, regulation, and winding up of trading companies and other associations were consolidated and amended, and came into operation on the 2nd November, 1862. By it no company, association, or partnership, consisting of more than ten persons, shall be formed after the commencement of the Act for the purpose of carrying on the business of banking, unless it is registered as a company under this Act, or is formed in pursuance of some other Act of Parliament, such as a local or personal Act, or 7 Geo. IV., c. 46, which is not repealed, or in pursuance of letters patent; and no company, association, or partnership, consisting of more than twenty persons, shall be formed for the purpose of carrying on any business, unless it is registered as a company under this Act, or is formed in pursuance of some other Act of Parliament, or of letters patent, or is a company engaged in working mines within, and subject to the jurisdiction of, the Stannaries. This Act is divided into nine parts, relating to the following subject matters:—1. To the constitution and incorporation of companies under the Act. 2. To the distribution of the capital, and liability of members of companies under the Act. 3. To the management and administration of such companies. 4. To the registration office. 6. To application of the Act to companies registered under the Joint-stock Companies Act. 7. To companies authorized to register under the Act. 8. The application of the Act to unregistered companies. 9. To repeal of acts, and temporary provisions.

Any seven or more persons may, by subscribing

their names' to a memorandum of association and registering the same, form a company, with or without limited liability. The liability of the members may be limited to the amount, if any, unpaid on the shares held respectively by them, or to such amount as they may respectively undertake by the memorandum of association to contribute to the assets of the company. Where the formation is on the principle of limited liability, the memorandum must contain the following things:—1. The name of the proposed company, with the addition of the word 'limited' as the last word in such name. 2. The part of the United Kingdom in which the registered office of the company is situate. 3. The objects of the company. 4. A declaration that the liability of the shareholders is limited. 5. The amount of the capital divided into shares of a fixed amount. When a company is formed on the principle of the members undertaking to contribute to the assets of the company to a certain amount, the first three of the above requisites are needful, and then a declaration of undertaking to contribute a sum not exceeding a certain amount, in the event of the company being wound up. Where no limit is placed on the liability of members, then only the first three requisites. The Act in a schedule supplies the rules, or 'articles of association,' which shall govern it; but these may be to such form as the promoters may think proper, provided such articles are registered with the memorandum of association. Any member may have, on request and the payment of one shilling, a copy of such memorandum and articles.

A register of the names, addresses of, and number of shares taken by, the members must be kept open to the inspection of every one, to members free, and to others on payment of one shilling. A copy of this register must at least once a year be sent to the registrar of joint-stock companies.

The liability of a member ends after he has ceased to be a member for one year; and he is liable to contribute to no debt contracted after he has ceased to be a member. The present members are liable in the first instance. The liability extends only to the amount subscribed for by each member.

All mortgages and charges on the property of the company must be registered. Limited banking companies, and insurance and deposit, provident or benefit societies under the Act, must at certain stated times make a return of its assets and liabilities, and place the same in a conspicuous part of its offices. The articles of association may be altered at a general meeting by a special resolution, carried by the vote of the majority at such meeting, provided not less than three-fourths of the members be present. Upon the application of a certain number of members, the Board of Trade may appoint an inspector to examine into the affairs of the company, the application being supported by such evidence as the Board of Trade may require. A company may be wound up, 1. Whenever it has passed a special resolution requiring the company to be wound up by the Court. 2. Whenever it does not commence its business within a year from its incorporation, or suspends its business for the space of a whole year. 3. Whenever the members are reduced in number to less than seven. 4. Whenever the company is unable to pay its debts. 5. Whenever the Court is of opinion that it is just and equitable that the company should be wound up. The

'Court' is defined to mean the Court of the vice-warden of the Stanneries, where his jurisdiction extends; the High Court of Chancery, when a company is registered in England; when in Ireland, the High Court of Chancery there; when in Scotland, the Court of Session in either division thereof. The Courts of Chancery in England and Ireland may order the proceedings to be transferred to the Court of Bankruptcy. Under the proceedings in winding up a company an official liquidator is appointed, whose duties are to collect the assets of the company, to settle the list of contributories, and generally to liquidate the affairs of the company.

The Act is to extend to all joint-stock companies registered under the Joint-stock Companies Acts of 1856, 1856–57, 1857, and 'the Act to enable Joint-stock Banking Companies to be formed on the principle of Limited Liability,' but not to the Act of 8 Vict., intitled 'an Act for the Registration, Incorporation, and Regulation of Joint-stock Companies.' The regulations for registering old companies under the Act are very special and numerous, and would be out of place here. It may be noted, that no banking company claiming to issue notes in the United Kingdom is entitled to limited liability in respect of such issue, and that where a bank is registered under this Act a special notice must be given to all its customers.

The effect of this enactment has been something marvellous, the capital now embarked in limited liability being, at the last return (April, 1866), upwards of a thousand millions sterling. Persons who hitherto could not embark in undertakings whereby they hoped to extend the amount of profit on their capital, because they shrank from the endless liability they incurred, now can enter into partnership in a legitimate trading, knowing for a certainty at the outset the full extent to which they may be called upon. Doubts exist in the minds of many whether the effect of this Act has not rather been pernicious than otherwise, seeing the enormous amount of speculation it has produced. On the other hand, the principle is sound, and trading is largely induced and greatly extended; and it is hardly an argument that because unprincipled persons turn to evil a good principle that that principle should not be extensively and legitimately used.

JOINT TENANCY signifies joint ownership of two or more persons in land, or other property, as goods and chattels. It differs from Tenancy in Common and Coparcenership in the following essentials: Joint tenants are considered to be severally seised or possessed of the undivided whole of the land or other property in which they have a joint interest, and also of their several shares, which shares are always equal shares, inasmuch as joint tenants take by purchase only, and by a joint title: the estate or interest must be limited to the several persons by the same deed or instrument, and such estate or interest must vest in them at the same time, except (according to the more common opinion) the estate be limited to take effect under the Statute of Uses or by devise, in which case the contemporaneous vesting of the several parts is not necessary: the whole estate or property goes to the survivors and survivor of the joint tenants if the jointure continue until such survivorship; which is the important characteristic of a joint tenancy. Any

joint tenant may transfer his interest to any one of his companions by release; and any joint tenant may convey his share to a stranger by grant; or he may compel his companions to make a partition. Every person to whom the interest of a joint tenant is transferred becomes, as to such share, a tenant in common with the remaining joint tenants.

A joint tenant cannot dispose of either the whole or the part of the property in which he is jointly interested consistently with the proper notion of a joint tenancy, by a will made during the continuance of the joint tenancy, even though he should happen to be the survivor; because until he has survived he has nothing to dispose of by will. But by severing the joint tenancy he acquires the power of disposing of his share by will. By the Act of 1 Vict., c. 26, a person may, by a will made according to the provisions of that Act, dispose of all real and personal estate to which he shall have a legal or equitable title at the time of his death, and which, if not disposed of by will, would go to his heir, or the heir of his ancestor, or to his personal representatives. But this Act gives no power of disposal over the unsevered interest of a joint tenant.

JOINTURE is the income secured to a wife for life under her marriage settlement, and is accepted in lieu of dower.

JOINVILLE. [MARNE-HAUTE.]

JOINVILLE, JEAN, SIRE or LORD DE, born of a noble family of Champagne. Joinville accompanied Louis IX. of France in his first crusade in 1248, and his narrative of the six years during which that crusade lasted is extremely interesting. It is entitled 'Histoire de St. Louis IX., Roi de France, par Jehan Sire de Joinville,' and has been often republished. One of the best editions is that by Ducange, folio, 1668. It has been translated into English by T. Johnes, 2 vols. 4to, 1807. Joinville, after his return to his native domain, continued to enjoy Louis' confidence. Joinville avoided the court of Philip le Bel, but is said to have joined the army which Louis X. collected at Arras against the Flemish. He died not long after; but the precise date is not known. Joinville and his predecessor, Villehardouin, are among the oldest of the French chroniclers who wrote in the vernacular tongue.

JOLIBA. [QUORRA.]

JONAH is one of the twelve minor Hebrew prophets. It is said in 2 Kings xiv., that he was the son of Amittai, of Gath-hepher, a city of the tribe of Zebulun. From the remainder of the passage some critics have supposed that Jonah lived under Jeroboam II., who reigned from 823 to 782 B.C., while others think that Jonah prophesied of Jeroboam, and was consequently much earlier—probably the earliest of the prophets whose time can be ascertained. There is no authentic information concerning Jonah later than what the book of Jonah records. The probability is that he returned from Nineveh to his own country, and died there. The history of Jonah is referred to in several passages of the New Testament (Matt. xii. 39–41; xvi. 4; Luke xi. 29, 30, 32), from which it appears improbable that the book of Jonah is to be considered merely a story of the nature of a parable, as some have supposed. The canonical authority of the book is generally admitted.

JONES, INIGO, was born in 1573, in the neighbourhood of St. Paul's, London. By his talent for drawing he attracted the notice of William, earl of Pembroke, by whom he was sent to Italy, and found himself in an entirely new world of art, which he carefully studied. Jones returned to England in 1605, and was employed at court in devising the machinery and decorations of masques and pageants. He was appointed architect to the queen and to Prince Henry. After a second visit to Italy he was employed to build the palace at Whitehall; and soon after the only portion ever built of it, namely, the Banqueting House, was completed, he engaged in a task of a very different nature, that of ascertaining the origin and purpose of Stonehenge; but he left the question, as he found it, a subject for speculation.

The church of St. Paul, Covent Garden, York Stairs, and Ashburnham House, Westminster, yet remain among his works in the metropolis. To give a list of all the buildings attributed to him would occupy a considerable space. He died in June, 1653, at the age of eighty.

JONES, GENERAL SIR JOHN T., K.C.B., historian of the war in Spain, was born in 1783, and first obtained his commission in 1798, in the Royal Engineers. He distinguished himself in various campaigns, especially in the Peninsula under the duke of Wellington, and in 1837 he became a general officer, and K.C.B. He was the first officer who published a history of the war in Spain. His 'Journals of Sieges in Spain,' which is a storehouse of military information, was first published in 1813, and has since passed through various editions. He died at Cheltenham in 1843.

JONES, SIR WILLIAM, was born in London, September 28, 1746. William Jones, his father, was a mathematician of some eminence.

Jones, at the age of seven, was sent to the grammar-school at Harrow, where, during the last two years, he did not confine himself to the study of the classical writers, but learned the Arabic characters, and made some progress in Hebrew. During the vacations he studied the French and Italian languages.

In 1764, at the age of seventeen, he entered at University College, Oxford. In 1765 he went to reside in the family of Earl Spencer, in order to superintend the education of Lord Althorp. During the five years that he stayed there he made great acquisitions in Oriental literature, and obtained the reputation of being one of the first Oriental scholars of his age. In his twenty-first year he began his 'Commentaries on Asiatic Poetry,' which were written in Latin, and published in 1774, under the title of 'Poeseos Asiaticae Commentariorum Libri Sex.' In 1771 he replied anonymously in French to Anquetil du Perron, who had attacked the University of Oxford and some of its learned members in his introduction to the 'Zend-Avesta.' In 1772 Mr. Jones published a small volume of poems consisting chiefly of translations from the Asiatic languages.

In 1774 Mr. Jones was called to the bar. While diligently attending the courts of law, he wrote an essay on the law of bailments; but his legal studies were superficial. In 1783 he was appointed a judge in the supreme court of judicature at Fort William

in Bengal, and was knighted. A few weeks after he married Miss Shipley, the eldest daughter of the bishop of St. Asaph.

Sir William Jones arrived at Calcutta at the close of the year, where he was mainly instrumental in forming a Society 'for inquiring into the history and antiquities, the arts, sciences, and literature of Asia.' To the 'Asiatic Researches,' which were published by this Society, of which Sir William Jones was the first president, Oriental scholars in Europe are indebted for much of their knowledge of the literature and antiquities of the Hindus.

The study of Sanscrit principally engaged the attention of Sir William Jones during the first three or four years of his residence in Bengal. When he had attained sufficient proficiency in this language, he undertook to prepare a copious digest of Hindu and Mohammedan law. It was unfinished at the time of his death, but has since been completed under the superintendence of Mr. Colebrooke. The laws of Manu were translated by Jones, and published separately in 1794. He died at Calcutta, April 27, 1794, after a few days' illness. Besides the Latin, Greek, Arabic, Persian, Sanscrit, Turkish, and Hebrew tongues, Sir W. Jones knew enough of Chinese to translate an ode of Confucius, and was also well acquainted with nearly all the modern languages of Europe.

A complete edition of the works of Sir William Jones was published in six volumes 4to., 1799, and in thirteen volumes 8vo., 1807, with his life by Lord Teignmouth.

JONES, JOHN PAUL, was born in Scotland, July 6, 1747. The name of his father was Paul; the addition of Jones was assumed by the son after he grew up in life. He went to sea at the age of twelve, and, after making many voyages to America and other parts, was in 1768 made captain and supercargo of a vessel. Having made a good deal of money, he settled in Virginia in 1773, on a property which fell to him by the death of an elder brother. After the Declaration of Independence by the colonies, he offered his services in the war against his native country, in which he soon greatly distinguished himself. In 1778 and 1779 he cruised off the coasts of England and Scotland, and caused great alarm with his single ship. At Paris, Louis XVI. presented him with a richly ornamented sword bearing a flattering inscription, he was invested with the military order of Merit, and received in every way the most distinguished reception, both from the government, the court, and in general society. On his return to America, in February, 1781, a gold medal was voted to him by Congress. He then served till the peace under the French admiral D'Estaing, after which he proceeded to Paris with the appointment of agent for prize money. Some years afterwards he entered the Russian service with the rank of rear-admiral; but disputes with the Russian naval authorities soon compelled him to retire, on which he returned to Paris, where he died, July 18, 1792.

JONE'SIA, a genus of plants of the tribe *Cassieæ*, and of the natural family of *Leguminosæ*. The species are few in number, and indigenous in the islands of the Malayan Archipelago. They form trees which are highly ornamental.

JONGLEURS, the name of those itinerant musicians, who in the Middle Age were very numerous in France. They wandered about from province to province, singing, and performing on the flute, violin, or other instruments, at the courts of princes and nobles, by whom they were often liberally rewarded. They were something like the early troubadours or bards; and one of their earliest employments was to attend and perform for these troubadours, who, from deficiency of musical knowledge, were unable to sing their own compositions.

JONQUIL, or JONQUILLE (*Narcissus jonquilla*), rush-leaved daffodil, a plant of the natural order *Amaryllidaceæ*, or Narcissus family. The Jonquil is well known; being one of the prettiest and sweetest of this tribe, it is a favourite in most gardens. When decocted it yields an acrid emetic quality. Several closely-related forms are natives of Britain; as the common daffodil (*N. pseudo-narcissus*), the poet's narcissus (*N. poeticus*), and the pale narcissus (*N. biflorus*).

JONSON, BENJAMIN, was born in Westminster, in 1574, and educated at Westminster School. The early part of his life is somewhat uncertain; but it is known that he went to Cambridge, and on leaving college took to the stage, where he proved but an indifferent actor and at first an indifferent author. In 1598 his fame rose by the production of the comedy of 'Every Man in his Humour,' at the Globe Theatre, and from this time he wrote a play annually, for several successive years. His writings are numerous and well known. In 1616 he was made poet-laureate, with a salary of 100*l.* a year and a tierce of wine. He died August 6, 1637, and was buried in Westminster Abbey. His works have been edited by Gifford with great acumen and considerable research. An edition has been published by Moxon, with a memoir, also by Gifford. His plays are eighteen in number, of which 'Every Man in his Humour' is still occasionally played.

JONZAC. [CHARENTE INFÉRIEURE.]

JOPPA. [SYRIA.]

JORDAENS, JACOB, was born at Antwerp in 1594. He studied under Adam van Oort, and also received instruction from Rubens. His pictures are distinguished by powerful, brilliant, and harmonious colouring, as well as knowledge of chiaroscuro; but he is deficient in elegance and taste: he copied nature as he found it. He died in 1678, aged eighty-four. His works are very numerous.

JORDAN. [SYRIA.]

JORTIN, JOHN, D.D., was born in 1698, in London. He received his grammar education at the Charter House, whence he passed to Jesus College, Cambridge, of which he became a fellow.

While living at Cambridge he published a small volume of Latin poems. His college presented him to a living in Cambridgeshire, but he determined on residing in London, where he soon became an admired preacher. In 1751 he obtained the living of St. Dunstan in the East. In 1762, when Dr. Osbaldeston became bishop of London, Jortin was appointed his domestic chaplain, and was presented with a prebend in the church of St. Paul and the living of Kensington. He fixed his residence at Kensington, where he died in 1770, and was buried in the churchyard of that place.

Dr. Jortin published in 1731 a critical work of considerable interest, entitled 'Miscellaneous Observations on Authors, Ancient and Modern.' In 1751 the first volume appeared of his 'Remarks upon Ecclesiastical History;' and in 1758 he published his valuable 'Life of Erasmus.'

JORULLO. [MEXICO.]

JOSEPH I., Emperor of Germany, succeeded his father Leopold I. in 1705. He carried on the war 'of the Spanish Succession,' which had begun under his father, against Louis XIV. The allied armies under Prince Eugene and Marlborough were prosperous in his reign. The battles of Ramilies, Oudenarde, and Malplaquet, the deliverance of Turin by Prince Eugene, the surrender of Naples to the Austrians, and the permanent footing obtained by the Archduke Charles in Spain, seemed to have nearly decided the question, when Joseph died of the small-pox in April, 1711, leaving his brother Charles VI., the last male heir of the house of Hapsburg, to conclude the war.

JOSEPH II., eldest son of Maria Theresa and of Francis of Lorraine, was elected king of the Romans in 1764, and in the following year, on the death of his father, he became emperor. Joseph joined Catherine of Russia in a war against Turkey, which his general, Laudon, carried on with success, taking Belgrade and other fortresses in 1789. But the threatening aspect of affairs in France and Brabant arrested the progress of the Austrian armies, and Joseph himself died in 1790. The character in which Joseph is chiefly viewed is that of a reformer; but his reforms, though well intended, were not judiciously devised or ably carried out. They led ultimately to the separation of the Belgian provinces from the Austrian monarchy, and to an insurrection in Hungary which his successor Leopold had some difficulty in suppressing.

JOSEPHINE. [BONAPARTE, NAPOLEON.]

JOSEPHUS, FLAVIUS, the Jewish historian, was born at Jerusalem A.D. 37. By his mother's side he was descended from the Asmonæan princes, and his father Matthias belonged to a high sacerdotal family. Josephus was brought up at Jerusalem with his brother Matthias. He was early celebrated for his learning: and after long study and experience of the tenets of different sects, embraced those of the Pharisees. On the breaking out of the Roman war, he at first joined the party in favour of peace; but when, after the defeat of the Roman general Cestius, peace appeared hopeless, he acted with great vigour as a commander against the Romans, until he was taken prisoner by Vespasian, A.D. 67, after having defended the town of Jotapata to the last extremity. Instead of being put to death, as was the fate of his companions, he was received by Vespasian with honour, in consequence of his artfully predicting that Vespasian would shortly succeed Nero in the government of the Roman empire. He was present with Titus at the siege of Jerusalem, and endeavoured to prevail upon his countrymen to submit to the Romans. On the capture of the city, Titus offered to grant him anything he wished. He asked for the sacred books, and the lives of his brother and fifty friends. He received a large estate in Judæa, and upon going to Rome was admitted to the privileges of a Roman citizen by Vespasian, who

also gave him an annual pension and apartments in his own house. After the death of Vespasian, he continued to live in Rome in high favour with Titus and Domitian. The time of his death is uncertain; he was alive at the latter end of the first century, and probably at the beginning of the second.

The first work published by Josephus was the history of the 'Jewish War;' it was originally written in the Syro-Chaldaic language for the use of those Jews who lived beyond the Euphrates. He afterwards translated it into Greek for the benefit of the learned Romans. Many years afterwards, A.D. 93, Josephus published in Greek his great work on the 'Antiquities of the Jews.' He also wrote 'Two Books against Apion,' in reply to those Greeks who questioned the truth of the early part of his work on the 'Antiquities of the Jews.'

The works of Josephus have been frequently translated into most of the modern languages of Europe. The best English translation is by Whiston.

JOSHUA, a book of the Old Testament, so called because it records the exploits of Joshua, the son of Nun, who succeeded Moses in the command of the Israelites. Joshua led the Israelites over the Jordan, B.C. 1451, and in the course of seven years conquered the greater part of Palestine, and assigned a particular part of the country to each of the tribes. He died at the age of 110, and was buried at Timnath-serath, in Mount Ephraim (Josh. xxiv. 29, 30).

The author of the Book of Joshua and the time in which it was written are equally uncertain. But at whatever time it may have been written, the author appears to have compiled the greater part, if not the whole, of the work from very ancient documents, some of which were probably drawn up by Joshua himself.

The canonical authority of this book has never been disputed. In all the MSS. of the Old Testament it immediately follows the Pentateuch.

JOSS STICKS are small reeds covered with the dust of odoriferous woods and burned before idols in China.

JOUDPOOR. [RAJPOOTANA.]

JOUGS, an instrument of punishment formerly in use in Scotland and in some parts of the Continent. The jogs, called also jugs or joggs, consisted of an iron ring or collar fastened to a wall or post by several iron links. The collar opened by a hinge, and the culprit's neck was secured in it, by means of a staple and padlock. This form of punishment was in use for civil and ecclesiastical offences. Though the use of this instrument has for a century been discontinued, it may still be seen in some few country parishes of Scotland, hanging to the churchyard walls.

JOURDAN, MARSHAL, a soldier of fortune in the French army, and one of Napoleon's favourite generals. He first entered the army as a private soldier in 1778; became a chef-de-bataillon in 1791; and soon rose to be general of division. In this position he successfully commanded the armies of Ardennes, the North Moselle, the Sambre and Meuse, the Danube and Italy; and was present at the battles of Wattignies, d'Arlon, the capture of Charleroi, the battles of Fleurus and d'Aldenhoven, the capture of Bruxelles, Namur, Louvain, Liege, Cologne, Frankfort, the passage of the Rhine, &c.

He was governor of Naples in 1806, having been previously created a marshal of the empire. In 1811 he was governor of Madrid, and major-general to the king of Spain, Joseph Bonaparte, with whom he sustained a terrible defeat at Vittoria, by the allied troops under the marquis of Wellington. After this he retired from active military duty, and remained so with little interval until the restoration of the Bourbons, when he became a count and a peer of France, general-in-chief of the army of the Rhine, governor of Les Invalides, &c. He died at Paris in 1833. (*Mil. Cyel.*)

JOVIANUS, FLAVIUS CLAUDIUS, born in 331, served in the army of Julian in his expedition against the Persians, and when Julian was killed in 363, the soldiers proclaimed him his successor. Jovianus accepted from the Persians terms which were offensive to Roman pride; but he was obliged to submit, as his soldiers were in the utmost destitution. On his arrival at Antioch, he revoked the edicts of Julian against the Christians. He also supported the orthodox or Nicene creed against the Arians. He died on the 16th of February, in 364, being thirty-three years of age, after a reign of only seven months. The army proclaimed Valentinianus as his successor.

JOVINUS assumed the imperial title under the reign of Honorius, and, placing himself at the head of a mixed army of Burgundians, Alemanni, and others, took possession of part of Gaul, in 411. Ataulphus, king of the Visigoths, having made peace with Honorius, attacked and defeated Jovinus, who was taken prisoner and put to death at Narbo (Narbonne), in 412.

JOVIUS, PAUL. [*Giovio.*]

JUAN FERNANDEZ. [*Fernandez*]

JUAN DE ULLOA. [*Vera Cruz.*]

JUBILEE, THE YEAR OF, among the Jews, an important period of time, which occurred every seven times seven years, or rather every fiftieth year, when all slaves were set free. Those who had mortgaged their lands retook possession, and general rejoicings took place. In the year 1800, Pope Boniface instituted a sort of Jubilee for the Roman Catholic Church, to be observed once in every 100 years, when he granted a plenary indulgence and remission of sins to all who visited the churches of St. Peter and St. Paul at Rome, and remained there for fifteen days. The periods were afterwards remodelled by Clement VI. in 1350, to fifty years; by Urban VI. in 1839, to thirty-three years; and by Sixtus VI., to twenty-five years. In later jubilee years, the pilgrimages to Rome have gradually diminished, but the observance itself has been punctually maintained at each recurring period, with the single exception of the year 1800, in which, owing to the vacancy of the Holy See, it was not held.

JUDA, JUDEA. [*Jews; Palestine.*]

JUDAISM, the system of religion believed by the Jews, and all the laws, civil, political, and ritual, which are contained in the five books of Moses.

JUDAS MACCABÆUS succeeded his father Matthias, B.C. 166, as the leader of the Jews in their attempts to throw off the yoke of the Syrian kings (1 Macc. iii. 1). He was very successful against Antiochus and his successor Antiochus Eupator. Anxious, however, to render Judæa

independent, and feeling the difficulty of continuing the contest against the whole power of the Syrian empire, Judas sent ambassadors to Rome to solicit an alliance with the Roman people (1 Macc. i. 8; Justin, xxxvi. 3). This was readily granted by the Romans; but, before Judas could receive any assistance from his new allies, he ventured to attack the Syrian army under Bacchides, amounting to 22,000 with a force of only 800, and after an obstinate struggle was at length defeated, and perished in the contest, B.C. 160.

JUDAS TREE. [*Cercis Siliquastrum.*]

JUDE, THE EPISTLE OF SAINT, a book of the New Testament, was probably written by the Apostle Jude, who was surnamed Lebbeus and Thaddeus (Matt. x. 3; Mark iii. 18; John xix. 22). He is also called the brother of James (Luke vi. 16; Acts i. 13), and the brother of Christ (Matt. xiii. 55). The Epistle of Jude appears to have been written shortly before the destruction of Jerusalem.

The canonical authority of this epistle has been rejected by many, because the apocryphal books of Enoch and the Ascension of Moses are supposed to be quoted in it (v. 14, 9). But the greater number of the Fathers refer to it as a work of divine inspiration.

JUDGE (from the French *juge*, which is from the Latin *judex*). A judge in England and Wales is a man who presides in a court duly constituted, declares the law in all matters that are tried before him, and pronounces sentence or judgment according to law. There are judges of the three Superior Courts of Law at Westminster, judges in the Courts of Equity, judges in the Court of Bankruptcy called commissioners, judges in the Probate and Divorce and Admiralty Courts, and some others. Some judges are called recorders, and there are other names, but the name does not alter the nature of the office. When the judges simply are spoken of, the judges of the superior courts of common law are meant. There are fifteen judges of these courts: five in the Court of Queen's Bench, five in the Court of Common Pleas, and five in the Court of Exchequer. There are at present seven judges in equity.

The judges of the superior courts of law are appointed by the Crown. They hold their office during good behaviour, and notwithstanding the demise of the Crown (1 Geo. III. c. 23.). They can be removed by the Crown on the address of both houses of Parliament (13 Will. III., c. 2). The judges of the courts of equity are also appointed by the Crown.

Retiring pensions are given to the fifteen judges and to the judges in equity, under various acts of Parliament. The highest retiring pension is 5000*l.* which may be granted by the Crown to the lord-chancellor upon his resignation.

Judges of courts of record are not liable to prosecution for anything done by them as judges, but they may be prosecuted in Parliament. Nor are they liable to an action for any error in judgment or for wrongful imprisonment, at least when they are acting within their jurisdiction. Judges are punishable for bribery, by loss of office, fine, and imprisonment. The powers and duties of judges would form the subject of an elaborate treatise.

JUDGE-ADVOCATE, in military matters, an important functionary, appointed to officiate as public prosecutor on every general court-martial formed

for the trial of officers and soldiers accused of a breach of the Articles of War. There are different kinds of judges, as the judge-advocate-general, who is appointed under the sign-manual; the judge-advocate, deputed by commission from the Crown; the deputy-judge-advocate, acting under the authority of the judge-advocate-general; and the officiating judge-advocate, who is appointed by commanding officers abroad. The judge-advocate of the forces stationed in London is regarded as a civil officer, and allowed a salary from the civil department. The office is generally held by an experienced barrister in the confidence of the Crown. The duties of a judge-advocate are to register and record all the acts of a court-martial, and all the evidence, as nearly as practicable, in the exact words of the witnesses; to advise the court on points of law, of custom, and of form; and to call their attention to any deviation from the strict rules of order. It is also his duty to note down the opinion of each member of the court-martial as he delivers it, whether for or against the prisoner; but he is bound not to disclose the vote or opinion of any particular member.

JUDGE-ADVOCATE-GENERAL, the supreme judge in the administration of martial law. He is also the legal adviser of the Commander-in-Chief, and the Secretary of State for War. The salary is 2000*l.* a year, and the holder of the office must be a member of the House of Commons and of the Ministry. The *Deputy Judge-Advocate-General* is an officer holding a temporary commission as public prosecutor in every court-martial, at a salary of 1200*l.* The total cost of the department of the judge-advocate-general is estimated at 5445*l.* for the year 1866.

JUDGES' CHAMBERS. This name is given to the court near Chancery Lane, London, where a common-law judge sits nearly all the year round to dispose of applications which are chiefly matters of form, though necessary to the administration of the law.

JUDGES, *the Book of*, a book of the Old Testament, which gives an account of the history of the Israelites from the death of Joshua to that of Samson. The author of the book and the time in which it was written are equally uncertain. It is commonly ascribed to Samuel, though some have argued, from Judges xviii. 30, that it could not have been written till the time of the Babylonish captivity. The canonical authority of this book has never been disputed. It is placed in all the Hebrew MSS. immediately after the Book of Joshua. It is quoted by Philo and Josephus, and also by St. Paul in the Epistle to the Hebrews (xi. 32).

JUDGMENT is the sentence of the law pronounced by the court upon the matter in the record, and the remedy prescribed by law for the redress or punishment of injuries, the suit or prosecution being the vehicle by which the injury is brought before the court. Judgments are given under four heads of issues; on Demurrer, where the facts are admitted by the parties, and the law determined by the court; on Verdict, where the law is admitted and the fact disputed; by Confession or Default, where the defendant admits both the law and the fact; and on Non-suit or Retraxit, where the plaintiff acknowledges that neither the law nor the facts are sufficient to

support his case, and therefore abandons the prosecution.

Judgments are either interlocutory or final. Interlocutory judgments include all those which are given on account of the incomplete state of the case as brought before the court, and which do not go to the absolute merits of the case: such as judgments on pleas of abatement. But the largest class to which this term is applied are judgments which decide the right between the parties, but require some other proceeding to determine the amount to be recovered. This proceeding is commonly a writ of inquiry, directed to the sheriff, who impanels a jury, and proceeds to assess the amount of damages to which the party in whose favour the interlocutory judgment has been given is entitled. If, however, the suit is for a specific thing or sum, and the decision of the court determines whether the plaintiff is or is not entitled to recover the remedy he sues for, the judgment is final.

The mode of signing judgment, as it is termed, and thereupon suing out execution, in order to obtain the effect of the judgment, are matters that properly belong to treatises on legal procedure. The object of the execution is either to give the person who has obtained a judgment in his favour some particular thing, or compensation for it, or value out of the property of the defendant. Recent statutes have made great changes in the law as to the way in which judgments affect real property. These statutes are the Acts of the 1 & 2 Vict., c. 110, 2 & 3 Vict., c. 11, and 3 & 4 Vict., c. 82, by which decrees and orders of Courts of Equity and rules of Courts of Common Law, and orders of the lord-chancellor in matters of bankruptcy and lunacy, have the effect of judgments, and the security of the creditor has been extended from a moiety, which was given by 13 Edw. I., stat. 1, c. 18, West. 2, to the whole of the debtor's lands, including copyholds, and making leaseholds bound in the same manner as freeholds. And as all lands are included by the Acts over which the debtor may have a disposing power, judgments against a tenant in tail are binding on his issue; for the tenant might at any time have barred the entail. But the greatest alteration which those statutes worked was changing the effect of judgment before execution sued out, from a general lien to a specific charge upon the 'lands, tenements, rectories, advowsons, tithes, rents, and hereditaments' of which the judgment debtor might, at the time of entering up judgment, or at any time afterwards, be possessed, of any estate whatsoever, at law or in equity, or over which he might have any disposing power. All judgments were made binding on the persons against whom they are entered up, and against all persons claiming through them, the judgment creditor being entitled to the same remedies in a court of equity as if the debtor had by writing agreed to charge the lands, &c. The creditor is not, however, to proceed in equity to obtain the benefit of such a charge until the expiration of one year from the time of entering up such judgment; and, in case of bankruptcy, the judgment, unless entered up one year, is to give no preference to the judgment creditor beyond creditors for simple contract. A special proviso excepts purchasers, mortgagees, or creditors previous to the time when the act came into operation; and with respect to purchasers

for valuable consideration without notice, the rules of equity remain unaltered.

A judgment creditor, applying now for remedy to the Court of Chancery, will not be obliged to sue out the writ of *elegit* [ELEGIT]; for that which is agreed to be done is considered by a court of equity as actually performed, and the judgment creditor has, therefore, by virtue of his judgment alone, an equitable estate. If, however, a judgment creditor, having obtained any charge, or being entitled to the benefit of any security, should, before the property so charged or secured is converted into money and applied towards the payment of the judgment debt, cause the judgment debtor to be arrested, the benefit of such charge or security is deemed relinquished. The extent of such charge goes now to the interest at the rate of four per cent. on the judgment debt, as well as to the debt itself.

The late Acts affecting judgments are the 18 and 19 Vict., c. 15, the 23 and 24 Vict., c. 38, and the 23 and 24 Vict., c. 115, and now the last Act, which came into operation on the 29th July, 1865, and provides that no judgment (including registered decrees, orders of courts of equity, bankruptcy, and other orders, having the operation of a judgment), statute, or recognizance shall affect any land of whatever tenure until such land shall have been delivered in execution in pursuance of such judgment, &c.; and that every such execution shall be registered in the name of the debtor instead of in the name of the creditor; and every creditor to whom the land has been delivered in execution shall be entitled to an order of the Court of Chancery to be obtained in a summary manner for the sale of the debtor's interest in such land; and any other creditors with a charge on such land shall be served with notice of the order for sale, and the proceeds of such sale shall be distributed among the persons entitled thereto according to their respective priorities. This is a most important amendment in the law of judgments, and will lessen much the difficult questions which have often arisen between a purchaser of land and a judgment creditor. Still the questions that arise are intricate, and it would be difficult, even in an elaborate treatise, to say exactly what is the effect of the different acts referred to.

Judgments or rules or orders of inferior courts of record, in which a barrister of not less than seven years' standing shall preside, may receive the same effect as those of a superior court by a judge's order to remove them into a superior court. But until execution be actually sued out, they will not affect lands in the hands of purchasers, mortgagees, or creditors, except so far as they would affect them as judgments of an inferior court.

In criminal proceedings, after trial the defendant can move in arrest of judgment at any time before judgment is pronounced; but this can only be done upon error appearing on the face of the record, and no motion of this sort can be made in the defendant's absence, unless a verdict is found in which the jury reserve a point for the consideration of the court. After the judgment is recorded, a writ of error is necessary before it can either be reversed or altered. Formerly no judgment affecting the liberty of the individual could be pronounced in his absence; but this has been altered by the 11 Geo. IV. & 1 Wm.

IV., c. 70, which enacts that, upon trials for felonies or misdemeanours, judgment may be pronounced whether the person affected be present or absent, except only in such cases of information filed by leave of the Court of King's Bench, or in cases of information filed by the attorney-general where he prays that judgment may be postponed. The judgment of the court extends to the life and liberty of the offender, according to the punishment decreed to the offence against which the judgment is delivered. In some cases it extends to the compensation for forfeiture of the lands or goods, or both, of the offender; others induce a disability of holding offices or fix a lasting stigma on the offender; and a large proportion are merely pecuniary by stated or discretionary fines.

JUDICIAL COMMITTEE. [PRIVY COUNCIL.]

JUDICIAL SEPARATION. [DIVORCE.]

JUDITH, an apocryphal book of the Old Testament, contains an account of the invasion of Syria and Judæa by Holofernes, general of the Assyrians, and of the destruction of the Assyrian army, and the death of Holofernes through the courage and stratagem of Judith. The historical and geographical difficulties of this book are so great, and its narrative so improbable, that a great number of critics are disposed to consider it as a religious romance, probably written in the time of the Maccabees, to encourage the Jews in their struggles against the Syrian monarchs. Grotius considers it as an allegory, and Josephus, who seldom neglects an opportunity of extolling the valour of his countrymen, takes no notice of this story.

The book of Judith was originally written in Chaldee, from which it was translated into Latin by Jerome. It was also translated into Greek and Syriac. The English translation in the authorized version was made from the Greek.

JUGGURNAUTH, or JUGGERNAUT.

[VISHNU.]

JUGLANDACEÆ, a natural order of apetalous exogenous plants, consisting of trees or shrubs having eatable nuts and somewhat resinous leaves. The former are the walnuts and hickory nuts of the markets; the first produced by the genus *Juglans*, the latter by that called *Carya*. The timber of this genus is valuable, as likewise that of *Juglans niger*, the Black American Walnut.

JUGULAR VEINS are the large trunks by which the greater part of the blood is returned to the heart after having circulated in the head, face, and neck. There are two on each side; one external or superficial, and the other internal or deep.

JUGUM, among the Romans, a humiliating kind of punishment inflicted on their vanquished enemies. It consisted of two upright spears, with a third laid across, in the shape of a gallows; when those who had surrendered themselves as prisoners of war were compelled, by way of ignominy, to pass under the erection without arms or military accoutrements.

JUGURTHA, the illegitimate son of Manastabal, and grandson of Masinissa, was brought up under the care of his uncle Micipsa, king of Numidia, who sent him with a force to join Scipio Æmilianus in his war against Numantia in Spain. Jugurtha became a great favourite with Scipio. Micipsa adopted him, and declared him joint heir with his two sons Adherbal and Hiempsal. After Micipsa's

death (B.C. 118), Jugurtha effected the murder of Hiempsal, and Adherbal, escaping to Rome, appealed to the senate. Jugurtha, however, bribed some of the senators, and a commission was sent to Africa in order to divide Numidia between Jugurtha and Adherbal. The commissioners gave the best portion to Jugurtha, who soon after their departure invaded the territory of his cousin, besieged him in Cirta, and put him to a cruel death, B.C. 112. In the following year the Romans declared war against Jugurtha, and an army was sent to Africa under Calpurnius Bestia. After some fighting, Jugurtha obtained under favourable conditions the quiet possession of the usurped kingdom. But the treaty was not ratified at Rome, and Calpurnius being recalled, the Roman army under Aulus Posthumus was surprised by Jugurtha, and having passed under the yoke, evacuated Numidia. The new consul, Metellus, carried on the war with great vigour; but in the year B.C. 107 was supplanted in the command by Cains Marius, who took the towns of Capsa and Moleuca, and in a hard-contested battle defeated Jugurtha. After being exhibited in the triumph of Marius, he was put to death in prison. His two sons were sent to Venusia, where they lived in obscurity. The war against Jugurtha lasted five years; it ended in 106 B.C.

JUJUBE. The name of a plant and of its fruit, which is pulpy and resembles a small plum. The plant is a species of *Zizyphus*, a native of the East Indies. The fruit was formerly used in pectoral decoctions; but it is now in little reputation, except as a sweetmeat.

JULIAN ALPS. [ALPS.]

JULIAN PERIOD is a term of years often employed in chronology, in order to avoid the ambiguity attendant on reckoning any time antecedent to our era. The Julian period consists of 7980 years, and is reckoned as having begun 4713 years before our era, so that the present year, 1866, corresponds to 6579 Julian Period. The era of the creation, or Anno Mundi, which has been used by Christian and Jewish writers, cannot be considered a fixed point, as chronologists and controversialists are not agreed as to the precise time of its commencement, some placing the creation 4004 years B.C., others, such as the early Alexandrian Christians, 5502 B.C., and the Greeks and Russians at 5508 B.C. The Julian Period is produced by the multiplication of the lunar cycle 19, solar cycle 28, and Roman indiction 15.

JULIANESHAAB, 'Juliana's Hope,' a town and harbour in South Greenland, situated at the head of a sheltered fiord or creek, and enjoying a comparatively mild climate, considering its high northern latitude. Its principal trade is carried on with Denmark. Whalebone, reindeers' flesh, oil, and sealskins are exported. It has been selected as one of the chief stations on the proposed Great North Atlantic Telegraph Route (March, 1866), which is designed to connect Great Britain with America by a line of telegraphic wires from London, through Scotland, Shetland, and the Faroe Isles, to Iceland and the western shores of Greenland (Julianeshaab), across Davis' Straits to the coast of Labrador or Belle Isle, and to communicate through Canada with the vast telegraphic system of the United States. The total length of this route will be 1950 miles,

divided into five sections: Scotland to Faroe Isles, 250 miles; Faroe Isles to Iceland, 240 miles; Iceland to Greenland, 743 miles; Greenland to Labrador, 507 miles; Labrador to Canada, 210 miles. Population of district of Julianeshaab is about 2500, consisting of Danes, natives, and mixed blood. It is the largest settlement in the southern inspectorate of Greenland, and near it are the remains of most of the old colonies.

JULIANUS, FLAVIUS CLAUDIUS, son of Julius Constantius, brother of Constantine the Great, was born in 331. After Constantine's death, the soldiers massacred the brothers, nephews, and other relatives of that prince, in order that the empire should pass undisputed to his sons. Two only escaped from this butchery: Julian, then six years old; and his half-brother, Gallus, then thirteen years of age. Constantius exiled Gallus into Ionia, and intrusted Julian to the care of Eusebius, bishop of Nicomedia, and he was instructed in Greek literature by Mardonius, a learned eunuch. About the age of fourteen he was sent to join his brother Gallus in Cappadocia, where they were treated as princes, but closely watched. The youths were taught the Scriptures, and were even ordained lecturers, and in that capacity publicly read the Bible in the church of Nicomedia. The death of Constantine and Constantine having left Constantius sole master of the Roman world, that emperor, who was childless, sent for Gallus in March, 351, and created him Cæsar, and he allowed Julian to return to Constantinople to finish his studies. There Julian met with the sophist Libanius, who afterwards became his friend. Constantius soon after again banished him to Nicomedia, where he became acquainted with some Platonist philosophers. After the tragical death of Gallus in 355, he was recalled to court by the influence of the Empress Eusebia, when Constantius named him Cæsar, and gave him the government of Gaul, together with his sister Helena to wife. Julian made four campaigns against the Germans, in which he displayed great skill and valour, and freed Gaul from the barbarians. He spent his winters at Lutetia (Paris), and became esteemed for his equitable and wise administration. Constantius, always suspicious, ordered Julian to send him back some of the best legions in Gaul to be employed against the Persians. In 360, he therefore assembled the legions at Lutetia, and bade them farewell, when an insurrection broke out among the soldiers, who saluted him Augustus. Julian sent messengers to Constantius to deprecate his wrath, but the death of the emperor left the throne open to him in 361. He proceeded to Constantinople, where, being proclaimed emperor in December, 361, he reformed the prodigality of the household, issued several wise edicts, corrected many abuses, and established a court at Chalcedon to investigate the conduct of those who had abused their influence under the preceding reign. On assuming the purple, Julian had openly professed the old religion of Rome, and, though he had issued an edict of universal toleration, he soon showed a marked hostility to the Christians, and many were imprisoned, tortured, and even put to death. Julian has been called the Apostate, but it seems doubtful whether after his boyhood he had been a Christian in his heart. That he was no believer in the vulgar mythological fables is evident

from his writings, especially the piece called 'The Cæsars,' and yet he professed great zeal for the heathen divinities.

Julian, having resolved on carrying on the war against the Persians, repaired to Antioch. His neglected attire, his uncombed beard, and the philosophical austerity of his habits drew upon him the sarcasms of the population of Antioch. The emperor revenged himself by writing a satire against them, called 'Misopogon.' He set off on his expedition with a brilliant army, crossed the Euphrates, took several fortified towns of Mesopotamia, crossed the Tigris and took Ctesiphon, but here his progress ended. The close Roman legions were harassed by the light cavalry of the Persians, and reduced to great distress for want of provisions. Sapor, the Persian king, was, however, inclined to come to terms, when in a skirmish Julian received a mortal wound. He expired the following night, June 26, 363, with perfect calmness and composure.

JÜLICH-CLEVE-BERG, the name given to a former division of the possessions of Prussia on the Rhine, which now forms the governments of DÜSSELDORF and COLOGNE, and part of the government of Aachen in the Prussian Rhein-Provinz. The territory so named was composed of the three ancient duchies of Jülich, CLEVES, and BERG. The town of *Jülich*, from which the duchy of Jülich was named, stands on the Roer, about 26 miles W. from Cologne, and has 2890 inhabitants, who manufacture soap, leather, and woollen cloth. It is fortified; and the foundation of the place is attributed to Julius Cæsar.

JULIS, a genus of Labroid fishes, remarkable for its various colours, is distinguished by its smooth head, and gill covers without scales. Mantell conjectures that the more tortuous kinds of coprolites, long known by the name of Juli, may have been fossil fir cones.

JULIUS I., II., III. [POPE.]

JULY, now the seventh, was originally the fifth month of the year, and was called by the Romans, in regard to its numerical station, *Quintilis*. In the old Latin or Alban calendar, *Quintilis* had a complement of 36 days. Romulus reduced them to 31; Numa to 30; but Julius Cæsar restored the day of which Numa had deprived it, which it has ever since retained. Our Anglo-Saxon ancestors called July *Mæd-monath*, 'mead month,' from the meads being then in their bloom.

JUMNA, a river of India, tributary to the Ganges, which it joins at Allahabad, inclosing with that river the territory called the Doab. It rises among the peaks of the Himalayas, at an elevation of 10,849 feet, and the total length of its course is estimated at 860 miles, the breadth varying at different seasons from 100 to 600 yards. It is generally shallow, and, except to descending rafts, unfit for navigation; but its uses for agricultural purposes have been much increased. The cities of Delhi and Agra are on its banks.

JUNCA'CEÆ, a small order of endogenous plants, so named from *Juncus*, 'the rush,' which is considered its type, is composed of obscure herbaceous plants.

JUNCAGINA'CEÆ, a small and unimportant order of Endogens, consisting of marsh plants. *Triglochin* is the commonest genus, and inhabits the fresh or salt marshes of most parts of Europe.

JUNE, the sixth month of the year, named from the Latin Junius. Ovid, in his 'Fasti,' makes Juno assert that the name was expressly given in honour of herself. In another part of the 'Fasti' he gives the derivation à *junioribus* (the younger), as May had been derived from *Majores* (the elder). In the old Latin calendar June was the fourth month, and consisted of twenty-six days. Thirty days were afterwards assigned to it.

JUNGERMANNIA'CEÆ, a rather extensive natural order of cryptogamic plants, or Acrogens, resembling mosses in appearance, but very distinct from them in many points of structure. The species inhabit the trunks of trees, damp earth, or even the young shoots and leaves of other plants in cool moist climates, especially such as are temperate. Some have the stem and leaf formed into a frond, or thallus, resembling that of a lichen, but more commonly the species have leaves with stipules at their base.

JUNGFRAU ('the Maiden') is the name of a lofty summit of the Swiss Alps, on the boundary line between the cantons Berne and Valais, 13,671 feet above the sea. It is surrounded on all sides by rocks and precipices, and capped with perpetual snow; but its summit has been attained by several Alpine explorers, including Agassiz and Forbes. (See the various series of the *Vacation Tourist*.)

JUNIPERUS, a genus of hardy, evergreen, woody plants, belonging to the natural order *Conifera*. About twenty species are known, the most important of which are the following:

J. communis, Common Juniper, growing wild in all the northern parts of Europe. Occasionally the Juniper becomes a small tree. The fruit is used in considerable quantities in the preparation of gin, and in medicine as a powerful diuretic. Oil of Juniper is said to be the most powerful of all diuretics in doses of four drops.

J. Sabina, Savin, is found wild in the middle of Europe and the west of Asia, inhabiting the most sterile soil, and is frequently met with in this country in shrubberies. Like the common Juniper, it is a diuretic and uterine stimulant, but is so powerful that its use is highly dangerous, except in the hands of regular practitioners. It is a well-known violent emmenagogue. Oil of Savin is a local irritant, producing blisters, when applied to the skin; taken internally, it is drastic and emetic.

J. Bermudiana, Bermuda Red Cedar, is very little known in Great Britain, in consequence of its not bearing the climate without protection. It is a native of the Bermudas, where it becomes a large tree, with a soft fragrant wood, the value of which is well known from its use in cabinet-work and the manufacture of pencils.

JUNK, a Chinese vessel, often of large dimensions. It has a high forecabin and poop, and usually three masts. Though junks are clumsy vessels, incapable of much seamanship or speed, they have proved themselves sea-worthy on voyages extending to Europe and America. The Japanese junk is superior to the Chinese.

The term *junk* is applied by British sailors to the salt meat supplied to vessels for long voyages.

JUNO, a Roman divinity, who has been commonly confounded with the Greek *Hera*. She was the daughter of Kronos and Rhea, the sister and wife of

Jupiter, the goddess of marriage and childbirth, and the protectress of married women. Her worship was of very great antiquity at Argos and in the Peloponnesus. The two most celebrated temples of Juno were at Argos and Samos.

JUNO. [PLANETS, SMALL.]

JUNOT, MARSHAL, DUC D'ABRANTES, was a soldier of fortune, who first attracted Napoleon's attention by his bravery in the field. He was born at Bussy-le-Forges in 1771. He first began to study for the law; but the political events of 1791 induced him to enlist in the battalion of volunteers raised in the department of Côte d'Or. He served under Bonaparte at Toulon, where he became a captain, as well as aid-de-camp to Napoleon. He accompanied Bonaparte to Italy in 1796; and to Egypt in 1799. Having greatly assisted him, on the 18th Brumaire, in overthrowing the Directory, he was made commandant of Paris, and created general of division in 1801. Eventually, under the patronage of the emperor, he became Duc d'Abrantes, and a Marshal of France. To him was intrusted the task of invading Spain and Portugal in 1807-8, where for some time he exercised his military tyranny; but at length he was signally defeated by Sir Arthur Wellesley at the battle of Vimiero, and compelled to evacuate the country. From this period he lost favour with Napoleon, and was refused employment in the campaign of 1813. Shortly afterwards his mental faculties became disordered; and he died in 1813. **MADAME, DUCHESS OF ABRANTES**, wife of Marshal Junot, after the fall of Napoleon, was obliged to support herself by the efforts of her pen, in consequence of all her family estates being confiscated. Her principal work was 'Mémoires et Souvenirs historiques sur Napoleon,' published in 1831, which had a prodigious sale. But she was at length reduced to extreme poverty, and retired to a maison de santé, where she died in 1838.

JUPITER, the supreme Roman deity, borrowed from the Greek *Zeus*. Jupiter was originally called Jov-is Pater, or Dies-piter, or Diu-piter, the *Diu* becoming softened in pronunciation into *Ju*, in the same manner as the Latin word *diurnus* has become *journal*. Jupiter, or Diupiter, would therefore mean the Father of day or the air; the first part of the word contains the same root as the Latin adverb *diu* and adjective *diu-rnus*.

Cicero says ('De Nat. Deor.' iii. 21) that there were three deities of the name of Jupiter: one the son of Æther; the second the son of Heaven; and the third the son of Saturn.

The Roman poets attributed to Jupiter the same power and attributes with which the Greeks invested Zeus, who was, according to Homer, the son of Kronos and Rhea. His wife was Juno (Hera), and their children Vulcan (Hephestus) and Mars (Ares). [**JUNO.**]

Jupiter was usually represented as seated on an ivory throne, with a sceptre in his left hand and a thunderbolt in his right. The eagle, his favourite bird, was generally placed by the throne.

JUPITER, the name of one of the old planets, the largest of all the bodies except the sun, in the solar system. The astronomical history of this planet is so completely entangled in that of the progress of astronomy in general and pure mathematics, that it would be useless to attempt any separation.

The figure of Jupiter is sufficiently oblate to appear of a sensibly spheroidal form in a moderate telescope, the axis of revolution being to the equatorial diameter in the proportion of 15·84 to 16·84, according to the recent researches of Mr. Main. The apparent equatorial diameter varies between half and three quarters of a minute, being 37''·91, when the planet is at its mean distance from the earth. The real equatorial diameter is 11·46 times that of the earth, or upwards of 91,000 miles. It is more than 1300 times as large as the earth, and its mean density is nearly the same as that of the sun, or about one quarter of that of the earth.

The mass of Jupiter, from the time of Newton to the present, was supposed to be to that of the sun in the proportion of 2 to 2141; but the recent observations of various astronomers make it somewhat greater. Mr. Airy's result is that the mass of Jupiter is to that of the sun in the proportion of 1 to 1046·77, or 2 to 2094 nearly.

The planet revolves on its axis in about 10 hours. Its light and heat are to those of the earth as 37 to 1000. Its sidereal revolution is performed in 4332·5848212 mean solar days.

The four satellites of Jupiter appear to revolve on axes, each in the time of its revolution round the planet, in the same manner as our moon. The times of their revolutions are, roughly, $1\frac{3}{4}$, $3\frac{1}{2}$, 7, $16\frac{3}{4}$ days, and their distances from the planet 6, 10, 15, and 27 of his semidiameter.

In consequence of the smallness of the angle by which Jupiter's equator is inclined to the ecliptic, and of the nearness of the orbits of the satellites to the plane of the equator, all the satellites except the fourth, which sometimes escapes, undergo one eclipse once in every revolution. Since this is caused by the entry of the satellite into Jupiter's shadow, the eclipse is independent of the earth's position, and the observation can certainly be made, unless Jupiter be too near to the sun. It never happens that both the immersion and emersion can be observed, in the case of the first satellite, and rarely in that of the second; though it is otherwise with the third and fourth. The reason is, that the planet itself always hides a part of its own shadow, and the first satellite is so near the planet that it must either enter or leave the shadow behind the planet: which also happens, for the most part, in the case of the second satellite. Before the planet is in opposition its shadow is on the western side of the planet, and after opposition on the eastern; while before the opposition immersions only are visible, and after opposition emersions, in the case of the first and second satellites. The eclipses of the four several satellites last about $2\frac{1}{2}$, $2\frac{3}{4}$, $3\frac{1}{2}$, and $4\frac{1}{4}$ hours one time with another. (See Guillemin's *Wonders of the Heavens*; Professor Airy's *Popular Guide to Astronomy*; Herschel, *On Astronomy*, &c.)

JURA, Island, one of the Hebrides, Scotland, immediately N.E. of Islay. It is the most rugged of the group, the surface being mountainous throughout; and in the south are three peaks, called the 'Paps of Jura,' the principal of which is 2566 feet high. The length of the island from N.E. to S.W. is 24 miles, the breadth varying from 2 to 8 miles. The estimated area is about 84 square miles, or 58,400 Scotch acres, only 600 of which are arable. The population in 1861 was 844, and 14 sailors. With

the adjacent islands of Balnahu, Garvelloch, Pladda, &c., it forms a parish, with a total population of 1052. The principal village is *Jura*, on the eastern and most populous coast. Oats, barley, potatoes, flax, slate, and iron ore, are the chief products of the island, whose scenery is very picturesque.

JURA, a department in France, formed out of the province of Franche-Comte, and named from the range of mountains that traverses it, is bounded N. by the department of Haute-Saône, N.E. by that of Doubs, E. by Switzerland, S. by the department of Ain, and W. by those of Saône-et-Loire and Côte-d'Or. It lies between $46^{\circ} 17'$ and $47^{\circ} 20'$ N. lat., $5^{\circ} 13'$ and $6^{\circ} 9'$ E. long.; its greatest length from N. to S. is 72 miles, from E. to W. 39 miles. The area is 1928 square miles, and the population in 1863 was 298,053.

Surface and Soil.—The department is diversified by mountains, plains, and marshes. Two-thirds of its extent are covered with the JURA MOUNTAINS, of which the highest summits are Reculet, La Dôle, and Mont-Poupet. The surface presents throughout its whole length three very marked and distinct divisions:—1, The western part, which consists of a low plain about 7 miles wide; 2, the first mountain elevation, which, rising suddenly from the plain, forms a plateau nearly 10 miles wide; and, 3, the high mountain district to the east of the other two, consisting of lofty summits and deep valleys, and extending in width as far as the other two divisions together. The soil of the plain, which consists of a marly clay resting on alternate beds of earth and shingle, is very productive in wheat, rye, maize, buckwheat, hemp, &c. On the plateau the soil is calcareous and shallow; it yields barley, oats, maize, nuts, &c. Potatoes also are an important crop. Among the mountains the soil is stony and thin, some barley and oats are produced; but there is abundant pasture, on which, during summer, from June to October, great numbers of cattle and horses are fed. During that season the châteaux, or solidly constructed huts, on the heights, serve as habitations for the herds, stores for the dairy produce, and as sheds for the cattle; in these the cows are milked, and butter and cheese are made. There is one herdsman for every 20 cows, and one cheesemaker for every 80. The cows from the different communes pasture in separate inclosures, each about 300 or 400 acres in extent and surrounded by a wall of dry stones; they come of their own accord to the châtlet to be milked by the herdsman, and immediately after return to pasture, for they never lair in the châtlet. In these annual migrations of the cattle, the milking and the cheese and butter making are entirely managed by men. An account is kept of the quantity of milk given by the cows of each owner, so as to apportion a just share of the butter and cheese, or of their price when sold. On the 9th of October (St. Denis' Day) the little establishments are all broken up, for then or soon after the rigours of a boisterous winter set in; the herdsman tie their wardrobe, no great burden, between the horns of the best cows, and the descent is commenced. But as all the cattle do not come from the same village, the herdsman follows only his own; the others, led by some sage old cow, direct their steps to their own village, where finally separating each one repairs to the house of her own master.

The farm buildings in the mountain districts are solidly built of stone and lime, but only 7 feet high, and covered with lengths of split fir, which are kept from being blown away by numerous stones laid on them. They include a dwelling-house, stable, barn, and hay-loft, all under the same roof, and communicating with each other. All the animals lair in the same stable, which extends quite across the building, and in which they are arranged in two rows, head to head, and feed from a manger that runs from one end of the apartment to the other. The cattle are never littered; but the floor is covered with loose planks, and overhead there is a covering of the same; otherwise the animals could not stand the cold of the winter, which generally lasts from six to eight months. In that part of the structure appropriated to the family the chief apartment is about 13 feet square; in the centre stands a stove, whence the smoke issues through a tube carried up a wide chimney, which by means of a trap-door is kept closed on the windy side, and serves for a window all the year, and during the deep snows for a door also, the ascent being made by means of a short ladder. Adjoining this apartment is a chamber containing beds for the father, mother, and the daughters of the family; the sons and men-servants, if any, sleep in the hay-loft.

Rivers.—The department is drained by a great number, the principal being—the AIN; the DOUBS; the Oignon, which bounds it on the north [DOUBS]; and the Loue, which enters it from the department of Doubs, and running W. enters the river Doubs, a few miles S. of Dôle. Of these the Ain, the Loue, and the Doubs are navigable. Among the smaller rivers the most important are the Bienne, the Cuisance, and the Furiense. The north of the department is crossed by the Canal-du-Rhône-au-Rhin. There are numerous marshes and lakes in the department.

Climate.—The climate is cold in the mountains, where the snow lies for six months; in the plain, which is cold enough in winter, owing to the proximity of the snow in the highlands, the air is hot and close in summer, but on the plateau pure and healthy during that season. High winds are frequent at all seasons; they are attended by heavy rains in spring, and oftentimes in summer also.

Natural Products, &c.—The agricultural produce is sufficient for the consumption. Horned cattle are exceedingly numerous; there are but few sheep; poultry, bees, game, and fish are abundant. The produce of wine amounts to 9,000,000 gallons annually, the best growths being those of the districts about Arbois, Château-Chalon, and Lons-le-Saulnier.

Several iron mines are worked; gold, copper, lead, and coal are found; the peat beds are dug for fuel; marble, gypsum, alabaster, and lithographic stone are quarried. There are important salt-works at Salins and Montmorot.

The manufacture of iron and iron wares is the most important object of industrial activity. The other manufactures are paper, watch and clock works; turnery in wood, bone, ivory, and horn; coarse woollens, linen, mineral acids, salt, casks, steel, scythes, nails of all kinds, tiles, and leather. About ninety fairs are held in the year.

Divisions, Chief Towns, &c.—The department is

divided into four arrondissements, which with their subdivisions and population are as follows:—

Arronds.	Cantons.	Communes.	Pop.in1863.
Lons-le-Saulnier,	11	212	101,189
Poligny, . . .	7	152	73,242
St.-Claude, . .	5	82	50,839
Dôle, . . .	9	137	72,783
Total, . . .	32	583	298,053

In the arrondissement of Lons-le-Saulnier the chief town, *Lons-le-Saulnier*, which is also the capital of the department, is situated at the foot of high vine-clad hills that surround it on every side, except the west, $46^{\circ} 40' 28''$, $5^{\circ} 33' 11''$ E. long., at a distance of 255 miles S.E. from Paris, and has 9862 inhabitants. It is a pretty well-built town, and lighted with gas; the principal street is lined with arcades; and there are several handsome fountains. In the northern angle of the town are the important salt-springs, from which the water is constantly pumped up into a wooden canal that conveys it to the great salt-works at Montmorot, about a mile distant from the spring. This salt well was discovered in the fourth century, and to it the town owes its foundation and its name; it is always full, although its waters are constantly extracted, and yield annually 20,000 quintals of salt. The town is the seat of tribunals of first instance and of commerce, of communal and ecclesiastical colleges; it has also a public library, a museum, and a theatre. The manufactures consist of hosiery, potash, and leather; the commerce is considerable in salt, iron, timber, wine, brandy, cheese, &c. *St. Amour*, 18 miles S. from Lons-le-Saulnier, has marble-sawing mills, naileries, tan-yards, and 2343 inhabitants. *Baume-les-Messieurs*, 6 miles from Lons-le-Saulnier, is a small place, situated in a wild rocky gorge on the Seile, and is famous for its ancient Benedictine abbey, the church of which is in tolerable preservation, and contains tombs of the counts of Bourgogne.

In the arrondissement of Poligny, the chief town, *Poligny*, which is situated at the extremity of an extensive plain, and at the foot of a spur of the Jura chain, near the source of the Glantine, at a distance of 14 miles N.E. from Lons-le-Saulnier, has a population of 5401. It consists chiefly of four well-built streets, parallel to each other, and to the direction of the mountain. It is well supplied with excellent water from the numerous fountains that adorn the town. Poligny has a college, manufactures of pottery, casks, hosiery, glue, saltpetre, and oil, also ironworks, dyehouses, tan-yards, and hydraulic saw-mills. Marble and alabaster are quarried in the neighbourhood. The tribunal of first instance is at *Arbois*, a pretty town 6 miles to the northward, at a height of 940 feet. Arbois has a college and 6672 inhabitants, who manufacture earthenware, paper, oil, and leather, and trade in the excellent white wines of the district. There are ironworks, hydraulic saw-mills, nitre-works, and nurseries at Arbois. *Champagnole*, a well-built town, with 3193 inhabitants, situated at the foot of Mont-Rivel, on the right bank of the Ain, and near the village and extensive ironworks of *Sirod*, is a place of some

commercial activity. It has a large iron-wire factory, hydraulic saw-mills, naileries, &c. *Salins*, 8 miles N.E. from Poligny, situated on the slope of a hill above the Furieuse, and near a narrow gorge between two high mountains, has a college, a library of 6400 volumes, a handsome church dedicated to St.-Anatole, and 7361 inhabitants. In the centre of the town are numerous salt-springs, and one of the greatest salt-works in France, which are inclosed by thick walls, flanked with towers, and extending 306 yards in length by 100 in breadth. Sulphate of soda, brandy, and leather are also manufactured, and in the neighbourhood there are gypsum-quarries, paper-mills, and ironworks. This town is inclosed by walls defended by two forts.

In the arrondissement of St.-Claude, the chief town, *St.-Claude*, situated between three wooded and rocky mountains, at the confluence of the Tacon with the Bienne, which is here crossed by a suspension-bridge, and at a distance of 25 miles S. by E. from Lons-le-Saulnier, has tribunals of first instance and of commerce, a college, and 6316 inhabitants. The town, which is the residence of the bishop of St.-Claude, is well built, and ornamented with some pretty promenades and handsome fountains. The cathedral church of St.-Pierre is the principal building. The place is famous for turnery in bone, ivory, horn, and wood; buttons, tobacco, and musical boxes, wind instruments, combs, hardware, pins, crape, cotton-yarn, leather, paper, tiles, and pottery are also manufactured. *Morez*, on the Bienne, is situated in a gorge formed by two mountains, which rise almost perpendicularly to the height of 1200 feet, and scarcely leave room between their naked sides for two rows of houses and the street that separates them. The population amounts to 4762, who maintain themselves by manufacturing iron, iron-wire, cotton thread, leather, and watch and clock movements.

In the arrondissement of Dôle the chief town is DÔLE.

The department forms the see of the bishop of St.-Claude, is included in the jurisdiction of the Cour Imperial and University Academy of Besançon, and belongs to the 7th Military Division, of which Besançon is head-quarters. To the Chamber of Deputies it returns two members. (*Annuaire pour l'An 1866*.)

JURA MOUNTAINS, the name given to a mountain system which consists of several parallel chains extending along the frontiers of France, Savoy, and Switzerland, in a direction from S.S.W. to N.N.E. from the Rhône and the Lake of Geneva to the left bank of the Rhine, towards the north, where it is connected by some lower elevations with the Vosges. The length of the system is about 180 miles; the breadth varies from 30 to 50 miles. The highest summits of the Jura Mountains are found in the most eastern chain, which is connected with the Bernese Alps and extends between France and Switzerland; the other chains diminish in height towards the west, and do not form continuous unbroken ranges, but rather consist of isolated elevations, connected at their bases. Very few of the valleys among these mountains are transversal; most of them run in the direction of the length of the chains. The highest points in the crest of the eastern chain are

those of Reculet, Tendre, La-Dôle, and Colombier, which rise respectively to 5959, 5543, 5513, and 5494 feet above the sea level; the mean height of this chain is about 4800 feet. The highest point in the second chain does not much exceed 4300 feet. The highest part of these mountains, which is full 3000 feet lower than the line of perpetual snow on the Alps, is covered with forests of pine and other resinous trees; further down, the beech, the ash, the lime, and the oak flourish; and the lower slopes are occupied with vineyards or cultivated for the production of maize or barley. The mountains also abound in excellent pasture, on which great numbers of cattle are reared and fed, and a great quantity of cheese is made. [JURA, Department.] Wolves are common; the brown bear and the wild cat are said to be met with, but rarely.

On the eastern side the chains of the Jura present in general steep abrupt flanks, but on the west they slope down by almost insensible degrees. They are composed of a hard gray limestone, mixed with alternate beds of marl and clay; in some places alabaster, gypsum, asphalt, coal, marble, and petrifactions of various kinds, especially those called oolites, are found. Iron mines, sulphurous and salt springs, abound; stalactitic grottoes and waterfalls are numerous; among the latter is the magnificent Saut du Doubs. [DOUBS.] An important and interesting feature of the Jura system, which gave name to the Jurassic formation, is the number of erratic stone blocks that are found high up the eastern slopes, at points opposite the opening of the great valleys which descend from the high Alps. Various theories have been proposed to account for the appearance of these massive blocks of a different kind of stone to that which prevails in the Jura; of these the theory of Venturi and Agassiz, who respectively ascribe the transfer of these blocks to floating ice and to glaciers at some long distant epoch, seems the most probable.

JURISDICTION. This term is the Latin word 'Jurisdictio,' which simply signifies the 'declaration of jus or law.' He who had 'jurisdictio' was said 'jus dicere,' to declare the law. The whole office (officium)

of him who declared the law was accordingly expressed by the word *Jurisdictio*. (Dig. 2, tit. 'De Jurisdictione.') *Jurisdictio* was either voluntary (*voluntaria*) or litigant (*contentiosa*). The *jurisdictio voluntaria* related to certain acts, such for instance as those forms of manumission and adoption which must be done before a *magistratus* in order to be valid. The *jurisdictio contentiosa* related to litigation, and such legal proceedings were said to be 'in jure,' before the *magistratus*, as opposed to the proceedings before a *judex*, which were said to be 'in judicio.' The *magistratus* was said 'jus dicere,' or 'reddere,' when he exercised his functions; and 'magistratus' and 'qui Romæ jus dicit' are accordingly convertible terms.

Jurisdiction in England means the jurisdiction of Parliament, which is, according to Sir Edward Coke, 'most capacious,' and according to other writers 'omnipotent;' and it also means an authority which a court of law or equity has to decide matters that are litigated, or questions that are tried before it.

The courts at Westminster have jurisdiction over all England and Wales; but the jurisdiction of other courts is limited by being confined to certain limits of space and to certain kinds of causes or matters in dispute. When the jurisdiction of a court extends over all England, it may still be limited as to the kind of causes which it tries. Thus the superior courts of law and the courts of equity have their several jurisdictions as to matters which they hear and determine. The ecclesiastical courts also have their separate jurisdiction; and other courts, such as the Court of Bankruptcy, County Courts, and others, have their several jurisdictions. If proceedings are commenced against a man before a court which has no jurisdiction in the matter brought before it, the defendant may answer by alleging that the court has no jurisdiction; which is called pleading to the jurisdiction. When a party is convicted by a court that has no jurisdiction in the matter, the proceedings may be moved into the Court of Queen's Bench by the writ of *Certiorari*, and quashed. By the 28 and 29 Vict., c. 99, a limited jurisdiction in equity has been given to the County Courts.

A DICTIONARY OF
UNIVERSAL KNOWLEDGE.

JURISPRUDENCE.

JURISPRUDENCE, from the Latin *Jurisprudentia*, which signifies 'a knowledge of law.' Persons who were skilled in the law were called by the Romans *jurisprudentes*, or simply *prudentes*; and sometimes *jurisconsulti*. Jurisprudence means more than being simply acquainted with the rules of law, as they exist in any given system: it means such an acquaintance with them as implies a knowledge of the law as a whole or system, a knowledge of the several parts, of their relation to one another, and to the whole. The Roman *jurisprudentes*, who were writers on law, gave to the several rules of law which related to any given division of the whole matter a certain order and consistency; they developed, and explained, and arranged that which existed as an incoherent mass. Their influence on the development of law was great, both directly and indirectly; and the compilation of Justinian called the 'Digest,' or 'Pandect,' which is entirely composed of extracts from the writings of the Roman jurists, gave to their opinions the force of law in the Roman empire. The Roman jurists also wrote institutional or elementary treatises on that part of the law which they called *Privatum Jus*, of which the 'Institutiones' of Gaius are an example.

Jurisprudence generally, or general jurisprudence, is conversant about those principles which are inseparable from all systems of law, or common to all systems of law; for however systems of law may differ in fact, and however much they may appear to differ in form, there are fundamental principles which are common to all. The notions of possession, of property, of things which can be objects of property, of most of the ordinary contracts of life, of testaments, of intestacy, and the like, are essentially the same. The notions of person, natural and artificial, of right, of duty, and many other things, are universal, and necessarily the same. It is the business of general jurisprudence to explain all these common notions, and to reduce the whole matter which they comprehend to some general form or system, with which all particular systems of positive law may be compared. This has been done in various ways by various writers; but the best examples that we have are by the German writers on law. When general jurisprudence becomes a regular part of a law student's discipline, it will lead to a more comprehensive study of the matter of our own law, to a more correct conception of its parts, and their relations to one another; and consequently to a nearer approximation of the

JURY.

particular law of England to the true measure or standard of general law, in those cases in which our particular system deviates from it. The study of general jurisprudence would be a sure though a slow corrective of many of the evils under which our actual society suffers.

JURY is an assembly of men authorized to inquire into or to determine legal facts, and bound by an oath to the faithful discharge of their duty. The etymological derivation of the term is obviously from *jurō*, 'to swear,' whence we find this institution called in law Latin *jurata*, and the persons composing it *jurati*; in French *les jurés*, and in English *the jury*. In English law, when the object is inquiry only, the tribunal is sometimes called an inquest or inquisition, as in the instance of a grand jury or coroner's inquest; but when facts are to be determined by it for judicial purposes, it is always styled a jury. When the trial by jury is spoken of in popular language at the present day, it signifies the determination of facts in the administration of civil or criminal justice by twelve men sworn to decide them truly according to the evidence produced before them.

Inquiry into facts on behalf of the Crown by means of juries was frequent in England long before the trial by jury was commonly used in courts of justice for judicial purposes. Besides these juries of inquiry (*inquisitoria jurata*), there were accusatory juries (*jurata delatoria*), who presented offences committed within their district or hundred to the king or his commissioned justices. These inquests were immediately connected with the administration of justice, their duty being to charge offenders, who, upon such accusation, were put upon their trial before judges, and were afterwards condemned or 'delivered' by them according to the result of the trial. Though the character and duties of these accusatory juries are involved in much obscurity, there is little doubt that they formed the origin of our present grand juries. The number of persons composing juries of inquiry and accusatory juries was arbitrary, and might consist of more or occasionally of fewer than twelve men.

The third species of jury is the institution by which disputed facts are to be decided for judicial purposes in the administration of civil or criminal justice, and which is in modern times familiar to us under the denomination of *trial by jury*. The time at which this species of trial originated in England has been the subject of much discussion; and the

question, whether it was known to the Anglo-Saxons or was introduced by the Conqueror, has been warmly debated.

The traces of the trial by jury, in the form in which it existed for several centuries after the Conquest, are more distinctly discernible in the ancient customs of Normandy than in the few and scanty fragments of Anglo-Saxon laws which have descended to our time. The trial by twelve compurgators, which was of canonical origin, and was known to the Anglo-Saxons and also to many foreign nations, resembled the trial by jury only in the number of persons sworn. Besides this, the trial by compurgators, under the name of Wager of Law, continued to be the law of England until it was abolished, in 1833, by the Statute 3 & 4 Will. IV., c. 42, s. 13, and is treated by all writers, and noticed in judicial records ever since the Conquest, as a totally different institution from the trial by jury. The trial *per sectatores* or *per pares* in the county court, which has sometimes been confounded with the trial by jury, was in truth a totally different tribunal. The sectatores or pares were, together with the sheriff or other president, judges of the court, as are the suitors in the county courts at the present day. But the incidents of the mode of trial prevalent in Normandy long before the Conquest, correspond in a striking manner with those of our trial by jury as it existed for centuries afterwards. Thus in Normandy offenders were convicted or absolved by an inquest of good and lawful men summoned from the neighbourhood where the offence was surmised to have been committed. The law required those to be selected to serve on such inquest who were best informed of the truth of the matter; and friends, enemies, and near relatives of the accused were to be excluded. These incidents, though unlike our present mode of trial, are nearly identical with the trial by jury as it is described first by Glanville and afterwards by Bracton, and correspond almost verbally with the form of the jury process which has continued to the present day, by which the sheriff is commanded to return 'good and lawful men of the neighbourhood, by whom the truth of the matter may be better known, and who are not akin to either party, to recognize upon their oaths, &c.' On the other hand (as Madox remarks, in his 'History of the Exchequer,' p. 122), 'if we compare the laws of the Anglo-Saxon kings with the forms of law process collected by Glanville, they are as different from one another as the laws of two several nations.'

Though there are some traces of the trial by jury in the four reigns which immediately succeeded the Norman Conquest, it was not till a century afterwards, in the reign of Henry II., that this institution became fully established and was reduced to a regular system. The law of Henry II. introduced the trial by assize or jury in real actions, as a mode of deciding facts which the subject might claim as a matter of right. In the reign of John we first begin to trace the use of juries for the trial of criminal accusations. It is quite clear, however, from Bracton and Fleta, that at the end of the thirteenth century the trial by jury in criminal cases had become usual, the form of the proceedings being given by them in detail. (Bracton, p. 143.) Introduced originally as a matter of favour and indulgence, it gained ground with

advancing civilization, gradually superseding the more ancient and barbarous customs of battle, ordeal, and wager of law, until at length it became, both in civil and criminal cases, the ordinary mode of determining facts for judicial purposes.

It is a popular error that the stipulation for the *judicium parium* (or judgment by equals) in Magna Charta referred to the trial by jury. Coke, in his commentary upon Magna Charta, expressly distinguishes between the trial by peers and the trial by jury (2nd Inst. 48, 49); but Blackstone says, 'The trial by jury is that trial by the peers of every Englishman, which, as the grand bulwark of his liberties, is secured to him by the Great Charter.' ('Commentaries,' vol. iv., p. 349.) This is confounding two distinct modes of trial. The *judicium parium* was the feudal mode of trial, where the *pares*, or *convassalli ejusdem domini*, sat as judges or assessors with the lord of the fee to decide controversies arising between individual *pares*.

Until about the reign of Henry VI. the trial by jury was a trial by witnesses. The present form of the jurors' oath is that they shall 'give a true verdict, according to the evidence.' At what precise time this form was introduced is uncertain; but for several centuries after the Conquest, the jurors both in civil and criminal cases were sworn merely to *speake the truth*. Hence their decision was accurately termed *veredictum*, or verdict; whereas the phrase 'true verdict' in the modern oath is not only a pleonasm, but is etymologically incorrect, and misdescribes the office of a juror at the present day.

The earliest traces of the examination of witnesses or of evidence being laid before juries in England, which formed the commencement of a total change in their character, occur in the reign of Henry VI. The change was introduced by slow degrees, and though distinctly discernible in the reign of Henry VI., was not completely effected before the times of Edward VI. and Mary.

This view of the original character and office of the jury seems to account for the practice of fining or otherwise punishing juries by the court when they gave an unsatisfactory verdict—a practice which was partially continued, though not without remonstrance by legal authorities, after the nature of the institution had been changed. If juries, who were merely witnesses sent for to inform the courts of facts which they were presumed certainly to know, returned a wilfully false verdict, they were guilty of a contempt of justice, and might properly be punished; but when their character was changed, and their verdict depended, not on their own knowledge of the facts, but upon the impressions produced on their minds by the evidence, such a course of summary punishment became intolerable injustice, and though occasionally practised in the sixteenth century, was declared to be illegal soon after the Restoration by the celebrated judgment in Bushell's case, reported in Vaughan's Reports, p. 135.

The juries now in use in England in the ordinary courts of justice are grand juries, petty or common juries, and special juries. Grand juries are exclusively incident to courts of criminal jurisdiction; their office is to examine into charges of crimes brought to them at assizes or sessions, and if satisfied that they are true, or at least that they deserve more

particular examination, to return a bill of indictment against the accused, upon which he is afterwards tried by the petty jury. A grand jury must consist of twelve at the least; but in practice a greater number usually serve, and twelve must always concur in finding every indictment. No further qualification is required for grand jurors (except in the case of grand jurors at the sessions of the peace, provided for by the Jury Act) than that they should be freeholders, though to what amount is uncertain; or freemen, lawful liege subjects, and not aliens or outlaws.

Until the end of the thirteenth century the only qualification required for petty or common juries, for the trial of issues in criminal or civil courts, was that they should be 'free and lawful men': *freemen*, as holding by free services or free burgesses in towns; and *lawful* men, that is, persons not outlawed, aliens, or minors, but entitled to the full privileges of the law of England. The Statute 6 George IV., c. 50, entirely remodelled the law respecting juries. By this statute 'every man (with certain specified exceptions) between the ages of twenty-one years and sixty years, who has within the county in which he resides 10*l.* a year in freehold lands or rents, or 20*l.* a year in leaseholds for unexpired terms of at least twenty-one years, or who, being a householder, is rated to the poor-rate in Middlesex on a value of not less than 30*l.*, and in any other county of not less than 20*l.*, or who occupies a house containing not less than fifteen windows, is qualified and liable to serve on juries in the superior courts at Westminster and the courts of the counties palatine, for the trial of issues to be tried in the county where he resides, and also to serve on grand juries at the sessions of the peace, and on petty juries, for the trial of issues triable at such sessions in the county in which he resides.' The exceptions are—peers, judges of the superior courts, clergymen, Roman Catholic priests, dissenting ministers following no secular employment but that of a schoolmaster, serjeants and barristers-at-law, and doctors and advocates of the civil law actually practising; attorneys, solicitors, and proctors actually practising; officers of courts actually exercising the duties of their respective offices; coroners, gaolers, and keepers of houses of correction; members and licentiates of the College of Physicians actually practising; surgeons, being members of one of the royal Colleges of Surgeons in London, Edinburgh, or Dublin, and actually practising; apothecaries certificated by the Apothecaries' Company, and actually practising; officers in her majesty's navy or army on full pay; pilots licensed by the Trinity House; masters of vessels in the buoy and light service; pilots licensed by the Lord Warden of the Cinque Ports, or under any Act of Parliament or charter; household servants of the sovereign; officers of customs and excise; sheriffs' officers, high constables, and parish clerks.

Lists of all persons qualified to be jurors are made out by the churchwardens and overseers of each parish, and fixed on the church door for the first three Sundays in September in each year; these are afterwards allowed at a petty sessions, and then delivered to the high constable, who returns them to the next quarter-sessions for the county. The clerk of the peace then arranges the lists in a book, which is called the 'Jurors' Book' for the ensuing year, and

afterwards delivers it to the sheriff. From this book the names of the jurors are returned in panels to the different courts.

Special juries are composed of such persons as are described in the 'Jurors' Book' as esquires, and persons of higher degree, or as bankers or merchants; and it is the duty of the sheriff to make a distinct list of such persons, which is called the 'Special Jurors' List.' When a special jury is ordered by any of the courts, which must always be the result of a special application of one of the parties, forty-eight names are taken by ballot from this list in the manner particularly described in the statute, which are afterwards reduced to twenty-four by means of each party striking out twelve; and the first twelve of these twenty-four who answer to their names in court are the special jury for the trial of the cause. This applies only to trials in London or Middlesex, one set of forty-eight special jurors being summoned to each of the assize courts, who try all special jury cases.

The mode of objecting to a jury by the parties is by challenge. Challenges are of two kinds: challenges to the *array*, and challenges to the *polls*. The challenge to the array is an objection to the whole panel or list of jurors returned for some partiality or default in the sheriff or the under-sheriff by whom it has been *arrayed*. Challenges to the polls are objections to particular jurors, either on the ground of incompetency (as if they be aliens, or of insufficient qualification within the provisions of the Jury Act, 6 Geo. IV., c. 50), or of bias and partiality, or of infamy, as having been convicted of some infamous crime. Upon these challenges, the cause of objection must in each case be expressly shown to the court; but in trials for capital offences the accused is entitled to challenge *peremptorily* (that is, without giving any reason) thirty-five jurors. The king, however, as nominal prosecutor, has no right of peremptory challenge, though he is not compelled to show his cause of challenge until the panel is gone through, and unless a full jury cannot be formed without the person objected to.

One of the jury is appointed the foreman, and he generally delivers the verdict of the jury to the judge in court.

The trial by jury, originally established in France in criminal cases by the National Assembly, was retained in the French code. An account of the proceeding and of the qualifications and formation of the jury will be found in the 'Code d'Instruction Criminelle,' liv. ii. tit. 2, chaps. iv. and v. [CODES, LES CRIM.]

Anciently in Scotland all offences were tried by juries; at present all prosecutions of a higher nature must proceed by an assize or jury of fifteen men, who determine their verdict by a majority of voices. In 1815 a statute (55 Geo. III., c. 42) was passed, which established a jury court, not as a separate and independent tribunal, but as subsidiary to the Court of Session, for the trial of particular questions of fact to be remitted for trial by the judges of the Court of Session at their discretion. It was provided by the Act that, if the jury are not unanimous in twelve hours, they shall be discharged, and a new trial granted. The judges of this court, called the 'Lords Commissioners of the Jury Court in Civil

Cases,' are appointed by commission, and consist of a chief judge and two other judges. The Stat. 59 Geo. III., c. 35, which recites that the introduction of the trial by jury in civil cases by the former Act had been found beneficial, enacts a variety of improvements in the machinery of the jury courts, and makes them a permanent part of the judicial establishment of Scotland. By the Stat. 2 Geo. IV. and 1 Will. IV., c. 69, the jury court as a separate tribunal was abolished, and the trial by jury was united with the ordinary administration of justice in the Court of Session.

JURY MAST, a mast erected in a ship to supply the place of one carried away in a tempest or in an engagement.

JUSSIEU, ANTOINE LAURENT DE, an

eminent French botanist, was born at Lyons in 1748. He arrived in Paris in 1765 for the purpose of completing his education as a medical practitioner, and in 1770 he was nominated botanical demonstrator in the Jardin du Roi. Shortly afterwards he drew up a memoir upon a new method of arrangement, which was read before the Academy of Sciences, and was afterwards carried into effect in the Jardin.

From 1774 to 1789 De Jussieu was constantly occupied in demonstrating to his class of botany; and as his new method was thus brought perpetually before him, with all its advantages and disadvantages in practice, he was able to alter and improve it yearly. The result was the following scheme, under which were arranged all the natural orders known to the author:—

Index Methodi
Ordines Naturales complectentis.

Stamens					Class				
Acotyledones,					1				
Monocotyledones,	{	{	Stamina hypogyna,		2				
			“ perigyna,		3				
			“ epigyna,		4				
			Stamina epigyna,		5				
			“ perigyna,		6				
			“ hypogyna,		7				
			Corolla hypogyna,		8				
			“ perigyna,		9				
			Dicotyledones,	{	Monopetalæ,	“ epigyna,	{ Antheris connatis,	10	
							{ Antheris distinctis,	11	
Polypetalæ,	Stamina epigyna,				12				
	“ hypogyna,				13				
	“ perigyna,				14				
	Diclinal irregularis,				15				

In the state of science when this system was promulgated its excellence was most remarkable, nor is it certain even now that in any way it can be much improved.

His ‘Genera Plantarum’ is now obsolete; but to the last day of his existence Jussieu preserved that brilliant combination of sound philosophical principles with a profound knowledge of facts which has placed him so far above all his countrymen as a botanist.

In 1789, when the ‘Genera Plantarum’ was published, the political state of France compelled Jussieu to mingle in the busy scenes of public life. In 1790 he was made a member of the municipality of Paris, and was charged with the direction of its hospitals and charities. In 1793 the Jardin du Roi was re-organized, and renamed the Jardin des Plantes; and De Jussieu became professor of rural botany. He was afterwards director and treasurer of the Museum of Natural History, and recommenced, in 1802, his botanical writings. These, amounting in number to fifteen, were continued in the ‘Annales du Museum’ till 1820. He employed himself between his eighty-third and eighty-eighth year in dictating a new edition of his ‘Introductio in Historiam Plantarum.’ He died on September 15, 1836.

JUSTICES, LORDS. The kings of England have been, ever since the Conquest, in the habit of appointing, as occasion required, one or more persons to act for a time as their substitutes in the government either of the whole kingdom or of a part of it. When William I. returned to Normandy the year

after the Conquest, he left his half-brother Odo, bishop of Bayeux, and William Fitzherbert, to be *Custodes Regni*, or guardians of the realm, during his absence; and similar appointments were very frequent under the early Norman and Plantagenet kings.

The most familiar case of the appointment by the Crown of a representative to exercise the supreme executive power, not in a colony or dependency, is that of the appointment of a governor for Ireland, who bears the name of the lord lieutenant, or of a council of government composed of lords justices.

In England lords justices and regencies have been repeatedly appointed since the Revolution, on occasion of the king going abroad; and the appointment has usually, if not always, been made by royal letters patent under the great seal, in the same manner as the lords lieutenant or lords justices of Ireland have always been appointed. In some cases, however, the aid of Parliament has been called in for certain purposes. The two judges who form one of the courts of appeal in Chancery are called the lords justices.

JUSTICES OF THE PEACE are persons appointed to keep the peace within certain prescribed limits, with authority to act judicially in criminal causes, and in some of a civil nature arising within those limits, and also to do certain other things in which they act not judicially but ministerially, *i.e.*, as servants of the Crown performing official acts, in respect of which they are intrusted with no judicial discretion. The authority of justices of the peace is derived from the king's prerogative of making courts for the administration of the law, or is created by

different statutes; their duties are expressed in the royal commission appointing them to the office, or are prescribed by those statutes.

Justices of the peace are appointed either by Act of Parliament, by royal charter (in the case of justices in boroughs not within the Municipal Corporation Act, the charter usually appointing certain municipal officers to be justices, and prescribing the manner in which vacancies in the offices are to be filled up), or by a commission from the Crown under the Statute of 1 Edward III. The form of the commission of the peace has from time to time been altered, and the authority of the justices enlarged. As now framed, it consists of two distinct parts, and contains two separate assignments or grants of authority. Of these the former gives to any one or more justices, not only all the power relating to the maintenance of the peace which was possessed by the conservators at common law, but also all the additional authority mentioned in the statutes. The latter assignment defines the power of justices when the whole body, or such of them as choose to attend, act together in general sessions. [SESSIONS.] The jurisdictions of justices in quarter sessions in criminal cases is defined by 5 & 6 Vict., c. 38.

Justices appointed by Act of Parliament or by the king's charter are not removable except for misconduct; but the authority of a justice appointed by the king's commission may be determined at the pleasure of the Crown, either directly by writ under the great seal, or impliedly, by making out a new commission from which his name is omitted. But until notice of the revocation of the authority, or publication of a new commission, the acts of the justice are valid in law; and the warrant of a justice remains in force until it be executed, although he die before its execution. The commission is also determined by the death of the king by whom it was issued; but by 6 Anne, c. 7, s. 8, all offices, civil and military, are to continue for six months after the demise of the Crown, unless sooner determined.

By 6 & 7 Vict., c. 73, s. 33, no attorney or solicitor while in practice is capable of being a justice of the peace. Justices of the peace have in general no authority over matters arising out of the district for which they are appointed, but they may secure the persons of those who are charged before them with felony or breach of the peace; and by the Municipal Corporation Act, s. 111, in every borough to which the king does not grant a separate court of quarter-sessions, the justices of the county within which such borough is situated are to exercise in it the same jurisdiction as in any other part of the county.

The judicial authority of a justice out of sessions is both civil and criminal—civil, where he is authorized by statute to adjudicate between master and servant, or to enforce the payment of rates, tithes, &c., or the observance of the regulations of friendly societies, &c.; criminal, where he requires surety of the peace or a recognisance for the peace or for good behaviour, or where he acts in the suppression of riots, or where he acts with summary power to decide upon the guilt or innocence of the party accused, according to the view which he may take of the evidence, and to punish the offender. But all proceedings before justices, whether civil or criminal, if removed into the Queen's Bench, are there treated

as belonging to the Crown side of the court. It is impossible here to enter into the particulars of the accumulated authority committed to these magistrates, but the reader is referred to Burns' 'Justices of the Peace.'

The office of justice of the peace was attempted to be introduced into Scotland by the Act 1587, c. 82, but without success. By the passing of the Act 1661, c. 38, however, a foundation was laid for the introduction of the system; and by the articles of union in 1707, and 6 Anne, c. 6, s. 2, the powers and duties of these magistrates in Scotland are now for the most part assimilated to the law of England on the subject. There is not, however, a *custos rotulorum* in the Scotch commission, and the *quorum* has never been introduced into the Scotch practice. (Hutcheson's *Justice of the Peace*; Barclay's *Digest*; Dunlop's *Parish Law*.)

The institution of justices of the peace has been adopted in most of the British colonies, and has with some modifications been retained in the United States of America.

JUSTICIA, a genus of acanthaceous Exogens, whose numerous species inhabit all the tropical parts of the world, preferring, however, damp woods to dry and open plains. It is especially in the forests of Brazil and India that they occur. Many of them are never woody, and some are bushes or small trees. A small number are valued by gardeners as objects of ornament. As now limited, Justicia scarcely contains a plant of any importance.

JUSTICIARY COURT (in Scotland.) The High Court of Justiciary is the supreme criminal tribunal in Scotland. Its jurisdiction extends to all crimes, and includes the whole of Scotland: and no appeal lies from its decisions. The constitution of this court was settled by the Act 1672, c. 16, enlarged and extended by subsequent statutes. At present it consists of the presidents of the two divisions of the Court of Session, and five other Lords of Session, any three being a quorum. It sits at Edinburgh from time to time during the year, according to the amount of business to be transacted: and holds circuits twice a year at the more important county towns for the more effectual distribution of justice throughout the kingdom. At these circuit courts appeals may be heard from the judgment of inferior judges in criminal cases, inferring neither death nor demerabration; and also in civil causes where the sum in dispute does not exceed 25*l.* sterling.

In other cases the sentences of inferior judges in criminal causes are brought by bill of suspension or advocacy before the High Court of Justiciary at Edinburgh, and in civil causes before the Court of Session. The jurisdiction of the High Court includes the cognizance of the crimes of treason, except where the accused is a peer, in which case he is tried by a Commission of Oyer and Terminer in the English manner. This court has also jurisdiction in all cases of new crimes.

JUSTIFIABLE HOMICIDE. [MURDER.]

JUSTIFICATION is used in theology to signify the acceptance of a sinner by God, and is frequently employed by the sacred writers as equivalent to the forgiveness of sin. Thus, St. Paul says, 'Be it known unto you therefore, men and brethren, that through this man is preached unto you the forgive-

ness of sins: and by him all that believe are justified from all things, from which ye could not be justified by the law of Moses.' (Acts xiii. 38, 39.) The Protestants and Roman Catholics differ respecting the signification that should be attached to the word justification.

The *originating cause* is the love of God towards his fallen creatures. (Rom. iii. 24; Eph. ii. 8.) The *meritorious cause* is, according to the 11th article of the Church of England, and the opinion of most Protestants, 'the merit of our Lord and Saviour Jesus Christ, and not our own works or deservings' (Rom. iii. 24; v. 18; Eph. i. 7; Col. i. 14); but the Roman Catholic Church maintains that good works, penances, and the intercession of saints also contribute to our justification. The *instrumental cause* is faith in the vicarious sacrifice of Christ; since the merit of Christ's sacrifice does not produce our pardon unless we believe in its efficacy. This is directly contrary to the doctrine of the Antinomians or Solifidians.

JUSTIFICATION, PLEA OF. This amounts to an admission of doing that which is complained of, such as libelling or slandering, and asserts that the libel or slander is true, and therefore justified.

JUSTINIAN'S LEGISLATION. The history of the Justinian legislation naturally divides itself into two periods, during the first of which the emperor's efforts were mainly directed to the methodizing and arrangement of the existing body of law, whilst during the latter his labours were chiefly addressed to supplementing its defects by new constitutions of his own. To the first period (528-534) belong:—
1. *Codex Vetus*. On 13th February, 528, shortly after ascending the throne, Justinian issued a commission to ten jurists, with Johannes the ex-quæstor of the palace at their head, and including Tribonian and Theophilus, to form a collection of the legislative enactments (*constitutiones*) of his predecessors from the time of Hadrian downward. Partial compilations of these had already been made. The codices of Gregorianus (306) and Hermogenianus (365) embraced the constitutions of all the heathen emperors for the three hundred years from Augustus to Constantine the Great; while the *Codex Theodosianus*, compiled by eight jurists at the order of Theodosius II., in 438, contained those of the Christian emperors from Constantine to his own time. From these materials, as well as from the 'Novellæ' of Theodosius, the code of Justinian was to be prepared. In about fourteen months (7th April, 529) this task was completed; and the new code, consisting of twelve books, and now entirely lost, received the force of law, and was made applicable to every subject of the empire.

2. *Pandectæ*, or *Digesta*. The following year (15th December, 530) Justinian commissioned Tribonian and sixteen others to digest the writings of the elder jurists into a regular and systematic exposition of Roman law, suited to the extended limits and the increased civilization of the empire. Full authority was given to the commission to abbreviate and to reject, and ten years were allotted for the accomplishment of the work. The commission having selected thirty-nine jurists of the greatest eminence, chiefly from the period which has been sometimes called the age of the Antonines—that is, from

Hadrian to the death of Alexander Severus, proceeded to divide into three classes all the books (numbering about 2000 works) from which extracts were to be made, and to form themselves into three sections—one for each of the several classes of treatises. 'The first section read and extracted from the books on the *jus civile*, to which belonged the *Libri ad Sabinum*; the second section extracted from the books on the *Prætorian edict*, especially from *Ulpianus ad Edictum*; and the third section, from practical and casuistical writings, especially from *Papinian's Responsa* and *Pauli Questiones*. Three branches of extracts were thus formed—the Sabinus branch, the Edict branch, and the Papinian branch. From these the single titles of the *Pandects* were composed. The foundation of each title was that which furnished most fragments.' (Mackeldy, 'Comp. of Modern Civil Law,' ed. Kauffmann, London, 1845, p. 52.) The extracts from Ulpian form more than one-third of the whole work; those from Paulus are next in number. In this way upwards of three millions of lines are said to have been condensed into 150,000.

The Digest was completed in less than three years. It was published on the 16th December, 533, and received the force of law on the 30th of the same month. All reference to the older jurists was in future forbidden; and all commentaries upon it were prohibited. Literal translations into Greek (*versiones xarà τῶδα*) were, however, permitted.

The work is divided into fifty books, subdivided into titles and laws.

3. *Quinquaginta Decisiones*.—During the compilation of the Digest, Justinian published his 'Fifty Decisions,' being the resolution of certain moot points of law, the contradictory opinions of the schools of Sabinus and Proculus upon which had been a source of annoyance and perplexity to Tribonian and his colleagues.

4. *Institutiones*.—While the Digest was being prepared, Justinian commissioned Tribonian and two other jurists, viz., Theophilus, professor of law at Constantinople, and Dorotheus at Berytus, to draw up an elementary work for the use of students, based upon the *Institutes* of Gaius and the *Codex Vetus* of Justinian. This work, which treats only of the *privatum jus*, was published on the 21st November, 533, and received the force of law on the same day as the Digest. It is in four books, and subdivided into titles.

5. *Codex Repetite Prælectionis*.—The old code having been found full of errors, a new edition of it was published, and obtained legal force on the 17th November, 534. This is the code we at present possess, the former one being now entirely lost.

To the second period of the Justinian legislation (535-565) belong the 168 *Novellæ Constitutiones*, written for the most part in Greek, and the thirteen *Edicta Justiniani*. Down to the time of Basil the Macedonian, in 867, the different compilations of Justinian remained the sole source of law. That emperor, however, made a reconstruction of the whole *corpus juris*, under the title of *Basilicæ*, which with various modifications continued in force till the fall of the Byzantine empire in 1453, during the reign of Constantine XIV.

JUSTINIANUS, FLAVIUS, born near Sardica in Mesia, in 482 or 483, of obscure parents, was

nephew by his mother's side to Justinus, afterwards emperor. The elevation of his uncle to the imperial throne, in 518, decided the fortune of Justinian, who, having been educated at Constantinople, had given proofs of considerable capacity and application. Justinian adopted Justinian as his colleague; and a few months before his death he crowned him in presence of the patriarch and senators, and made over the imperial authority to him, in April, 527. Justinian was then in his forty-fifth year, and he reigned above thirty-eight years, till November, 565, when he died. By means of his generals, Belisarius and Narses, he completely defeated the Vandals and the Goths, and restored Italy and Africa to the empire. Justinian was the last emperor of Constantinople who, by his dominion over the whole of Italy, reunited in some measure the two principal portions of the ancient empire of the Caesars. The wars of Justinian's reign are related by Procopius and Agathias.

Justinian must be viewed also as an administrator and legislator of his vast empire. In the first capacity he did some good and much harm. He was both profuse and penurious: personally inclined to justice, he often overlooked, through weakness, the injustice of subalterns; he established monopolies of certain branches of industry and commerce, and increased the taxes. But he introduced the rearing of silkworms into Europe; and the numerous edifices he raised, and the towns he repaired or fortified, attest his love for the arts, and his anxiety for the security and welfare of his dominions. He was, or professed to be, a poet and philosopher, a lawyer and theologian, a musician and architect; but the brightest ornament of his reign is the compilation of a code of Roman law. [JUSTINIAN'S LEGISLATION.] His love of theological controversy led him to interfere with the consciences of his subjects, and his penal enactments against Jews and heretics display a spirit of intolerance which has ever since been a dangerous authority for religious persecution.

Justinian died at eighty-three years of age, on the 14th November, 565, leaving no children, and was succeeded by his nephew, Justinus II.

(Ludewig, *Vita Justiniani Magni*; Gibbon, ch. xl.-xliv.)

JUSTINUS, commonly called JUSTIN MARTYR, one of the early Fathers of the Christian church, was born in Palestine, at a place then called Neapolis. Justin was carefully instructed in the learning of the Grecian schools of philosophy, and in the course of his studies he visited Alexandria, then a celebrated seat of learning. With a mind deeply imbued with the Platonic philosophy, he became sensible of the simple beauty of Christianity, and made a public profession that he received it as divine truth about 132.

Among the Fathers of the primitive church he is eminent by the Apologies and Defences which he published. His first Apology for Christianity was addressed to the Emperor Antoninus Pius and his adopted sons, at a time when the Christians were suffering rather from popular fury than from the regular authority of the state, and it prevailed so far as to obtain for them some favourable concessions from the emperor. His second Apology was addressed to the successor of Antoninus, Marcus Aurelius, on the occasion of several Christians having been put to death for their faith. The usual place of his resi-

dence was Rome, where he was put to death, a martyr to Christian truth; but the time is uncertain.

JUSTS, or JOUSTS, martial exercises or private combats which took place during the mediæval periods between knights and other distinguished persons of chivalrous spirit. They differed in some respects from tournaments, which consisted of many men in troops, while juts were contentions between man and man. On some occasions the combatants were on foot with spears, swords, or axes, and a barrier breast-high between them. In the Middle Age these juts became authorized by custom as trials of military prowess.

JUTE, the fibre of a plant of the genus *Corchorus*, and natural order *Tiliaceæ*. The plant is widely diffused in tropical countries, but is especially cultivated in India, yielding the jute of commerce, and the fibre employed in making gunny-bags. The inner bark is separated by maceration, in lengths from 6 to 12 feet, and constitutes the fibre of jute. It is only during the last thirty years that this material has come into use in Europe, and its progress has been extensive. It is chiefly used for making coarse bags, in which all the Indian produce of sugar, rice, pepper, ginger, saltpetre, gums, seeds, &c., is imported, and also the cotton of America and other places. Jute is also woven into mats and coarse carpets, and similar articles of domestic use.

Jute (*Corchorus capsularis*).

It does not make good rope, on account of its liability to rot from moisture. But by its extensive use in coarse bagging it takes the place of hemp, thereby setting free more of that article for the purposes of sailcloth and cordage.

Jute is usually imported in bales of about three and a half hundredweights each, and varies in price from 16s. to 24s. per cwt. The following table gives the imports into the United Kingdom for the years 1860-68:—

	Cwts.	£	Average Price.		
			£	s.	d.
1860	816,787	660,613	0	16	2
1861	904,092	703,961	0	15	9
1862	963,774	930,634	0	19	4
1863	1,232,335	1,549,928	1	4	11
1864	2,036,537	2,250,667	1	1	8
1865	2,108,942	1,774,992	0	16	10
1866	1,638,174	1,495,533	0	18	3
1867	1,597,192	1,442,977	0	17	10
1868	2,180,137	1,949,864	0	17	11

The exports of jute from the United Kingdom in 1868 were 415,266 cwts; of jute manufactures 43,127,402 yards, value 705,567*l.*; and of jute yarn 8,108,747 lbs. value 127,911*l.* The chief seat of the trade in Great Britain is Dundee, to which town the manufacture was exclusively confined for some years.

Sunn hemp (*Crotalaria juncea*), belonging to a family of plants which yield the pulses of India, has been used in cordage, but for textile purposes has been completely superseded by jute.

JUTES, a people who in the fifth century appear to have been settled in the northern part of the Danish province of Jutland, which took its name from them. They took part in the expedition of the Saxons to England, waged war with Charlemagne, and under the name of Normans (Northmen) frequently desolated the coasts of Germany and France.

JUTLAND, a large province of Denmark, formerly comprising the whole of the peninsula which projects northwards from Prussia and Germany, but since 1864 restricted to that part of it belonging to Denmark north of Schleswig, extending from 55° 23' to 57° 44' N. lat., and from 8° 7' to 10° 48' E. long. It is bounded E. by the Little Belt and the Kattegat, N. by the Skagerrack, and W. by the German Ocean. The southern part of the peninsula, extending from the frontier of Holstein to an irregular line from Kolding Bay to a point on the west coast opposite the extremity of the isle of Fanøe, constitutes the Prussian province of Schleswig.

Jutland is about 180 miles long, with a breadth varying from 70 to 100 miles. The area is 9597 square miles, and the population in 1860 was 699,939. Few countries have such an extensive line of coast (523 miles) in proportion to their area as Jutland, which is indented with numerous bays and inlets. Of these inlets, the *Lümfjord* extends across the north of the province, first in a western, and then in a south-western direction for about 100 miles. It contains numerous islands; the largest, called Mors, is 23 miles long and 11 broad, and has 6000 inhabitants. In 1825 the North Sea broke through the narrow strip of land between it and the *Lümfjord*, and the breach being gradually enlarged, the northern part of Jutland is now an island. The apparent advantage of this extensive line of coast is much diminished by the shallowness of the sea, and the innumerable little islands, sand-banks, and shoals, which render access difficult. The west coast is bordered by a chain of sand-hills, within which there are many good pastures. The southern part of the west coast is alluvial soil, extremely fertile, but swampy and unhealthy, and requiring dikes to protect it from the inroads of the German Ocean. The east coast is more elevated, and is well wooded, fertile in grain, and populous. The peninsula terminates northwards in the promontory of Skagen, from which a line of low hills runs through the whole length of Jutland. The rivers are very small; lakes are numerous. The principal river is the Guden, which is navigable for 50 miles, and is joined by the Silkeborg Canal. Others of less importance are the Stor, Skjern, Warde, and Lonborg. The highest point of the watershed is the Himmelsberg, 550 feet above the sea-level. The productions are corn, hemp, flax, tobacco, and some timber. The horses are large. The breed of black cattle is good, and numbers of

them and of hogs are exported to Holstein. Fish and game are abundant. The manufactures comprise linens, yarns, and hosiery for domestic use. The climate is very variable, with frequent fogs and rains; the winters are not very rigorous, but the summer is often extremely hot. The north-west wind, called *Skai*, which is especially felt in May and June, is so severe on the west coast as to wither the tops of the trees. The inhabitants are principally engaged in agriculture and seafaring pursuits. Jutland has belonged to Denmark since about 850. It is one of the few peninsulas that project northwards.

The peninsula is divided into ten amts or cantons:—AALBORG, AARHUUS, Hjørring, Ribe, Ringkjøbing, RANDERS, Skanderborg, Thisted, Viborg, and Weile. The town of *Viborg* is situated on a small lake nearly in the centre of the peninsula, and has 4861 inhabitants. It is surrounded with ramparts, has six gates, and is pretty well built. There are manufactures of woollen fabrics, leather, and tobacco. Its public garden contains the stone on which Hans Taussen, the Danish Luther, proclaimed the Reformation. *Ribe*, or *Ripen*, is a walled town with 2600 inhabitants. It is situated on the Rips, 2 miles from the German Ocean, within the territory of Schleswig. Only small vessels can come up to the town of that name. The fortress of *Fredericia* commands the northern entrance to the Little Belt; the town has 6261 inhabitants, four churches, a synagogue, a custom-house, and several manufactories. [BELT.] *Silkeborg*, the youngest town in the Danish dominions, is built on a site which twenty years ago was a waste. It has extensive and most successful paper manufactories. [DENMARK; SLESWIG-HOLSTEIN.]

JUVENAL. This name is variously written *Decius* (or *Decimus*) *Junius Juvenalis*. His birth-place was perhaps Aquinum, a Volscian town; and he is said to have been born somewhere about A.D. 40, under Caligula, and to have died, aged upwards of eighty, under Hadrian. In fact, nothing certain is known about him.

The relative merits of Juvenal and Horace as satirists have been warmly contested. It is a question on which men will form opposite opinions, as their tempers are more fit to relish brilliancy and playfulness, or earnest and dignified declamation. Juvenal is said to have spent much time in attendance on the schools of the rhetoricians; and the effect of this, in an age not remarkable for purity of taste, may be observed in a tendency to hyperbolical inflation, both of thought and style. His writings are addressed to the encouragement of virtue no less than to the chastisement of vice; and parts of them have been recommended by Christian divines as admirable storehouses of moral precepts. Still they lie open to the objection of descending so minutely into the details of vice as to minister food as well as physic to the depraved mind. The editions of Juvenal are very numerous; that of Ruperti, which has been much used in England, has a copious but not a valuable commentary. The edition of Heinrich, 8vo, Bonn, 1839, has a useful body of notes. He is translated into English by Holiday, Dryden (who, however, only translated five satires of the edition which bears his name), Gifford, Hodgson, and others.

K.

K has the same sound which C has before the vowels *a, o, u*. A reference to that consonant will therefore suffice for the power of the letter. Although this letter is now superfluous, it was not so when the characters of an alphabet were syllabic in power. Thus the letter *k* appears to have denoted at one time the syllable *ka*, while another character represented *ko*, and so on. Hence in the Greek and Hebrew alphabets the former was called *kappa, kaph*; the latter *koppa, koph*. This accounts for the fact, that in Latin the letter *k* was never used except before the vowel *a*, precisely as *q* is found only before *u*, and the Greek *koppa* only before *o*. Even our own alphabet seems to imply such a limit in the use of this consonant, when it gives it the name *ka*, not *ke*, though the latter name would better agree with *be, ce, de, &c.* K is silent before *n*, as in *know, knife, knee*. As a contraction, K stands for knight, as K.B., Knight of the Bath; K.G., Knight of the Garter; K.C.B., Knight Commander of the Bath; K.T., Knight of the Thistle; and K.H., Knight of Hanover.

KAABAH, or BAIT-ULLAH ('house of God'), the name of the sanctuary of Mohammed's Mosque at Mecca. It stands in the centre of the building, and, as described by its name (*Kaabah, i.e., 'cube'*), is an oblong, massive, windowless structure, built of fine gray granite in horizontal courses of masonry of irregular depth; the stones tolerably fitted together, and held by excellent mortar like Roman cement. According to the measurement of Captain Richard F. Burton, who visited it in 1853, at the risk of his life, and from whose 'Pilgrimage to El Medinah and Mecca' this account is principally derived, it is 22 paces (55 feet) in length, and 18 paces (45 feet) in breadth. Its height has been differently stated. Burckhardt gives it at from 35 to 40 feet, but to Captain Burton it appeared greater than its length. It stands upon a base called El Shazarwan (from the Persian *Shadarwan*, 'a cornice or canopy'), two feet in height, of penthouse shape, projecting about a foot beyond the wall, and composed of fine white marble polished like glass. The roof is flat, with a slight depression from S.W. to N.W. The only door which affords entrance is on the east side, and about seven feet from the ground. At the south-east corner, and between four and five feet from the pavement of white marble which surrounds the building, is placed the famous Hajar el Aswad, or Black Stone, an aerolite covered with a thick shaggy coating, glossy and pitch-like, worn and polished. 'Within this stone,' says an Arab tradition, 'Allah inclosed the covenant which he made with the sons of Adam. On the Great Day of Fealty and at the Judgment it will appear to bear witness to all who have touched it.' All Moslems agree that this stone was originally white, but became black by reason of men's sins.

KAABAH.

It is curious, however, to observe that the Hajar, as well as the Kaabah itself, are revered as holy emblems by four different faiths—the Hindoo, Sabbean, Gueber, and Moslem; and Captain Burton is also of opinion that it is connected with many Jewish traditions about Abraham. More recently, too, Bishop Colenso ('Pentateuch,' part v., app., p. 265, et seq.) has adopted the theory first advanced by Professor Dozy of Leyden, that this stone is an image of the god Baal of Simeonitish origin, and worshipped by the Israelites during the reign of King Saul. There can, however, be little doubt that the Hajar of the present day, and which is described by Burckhardt as composed of a dozen smaller stones of different sizes and shapes, joined together with cement, but looking as if the whole had been broken into many pieces by a violent blow, and thus united again, is the image of that *Hobal* (whether or not it may afterwards be decided that this divinity is the same as Baal) which was in the form of a man, and after the capture of Mecca, was broken in pieces by the orders of Mohammed. On the north-west side of the Kaabah are two large slabs of fine verde antico, which, according to Mohammedan tradition, mark the place where Ishmael and his mother Hagar are buried; and close to the door of this building is a slight hollow in the ground, lined with marble, and sufficiently large to admit of three persons sitting, called *El Maajan* ('the place of kneading'), where it is believed Abraham and his son Ishmael kneaded the chalk and mud which they used in building the Kaabah.

At the annual season of pilgrimage the Kaabah is decorated from top to bottom with the *Kiswah*, a robe of honour of black and gold, composed of silk and cotton tissue, and inscribed with sentences from the Koran. A gold embroidered curtain, denominated the *Burka*, or face veil, connecting the building in idea, perhaps, with the ancient practice of typifying the church visible as a virgin or bride, is hung across the door; while the old *Kiswah* of the year before is sold, and the proceeds appropriated by the Beni Shagbah family, the hereditary guardians of the sacred building. Entrance to the Kaabah can be obtained ten or twelve times during the year gratis, and by pilgrims as often as they can collect among themselves a sum sufficient to tempt the guardians' cupidity. 'Nothing is more simple,' says Captain Burton (vol. iii. p. 288), 'than the interior of this celebrated building. The pavement, which is level with the ground, is composed of slabs of fine and various coloured marbles, mostly, however, white, disposed chequerwise. The walls, as far as they can be seen, are of the same material, but the pieces are irregularly shaped, and many of them are engraved with inscriptions. The upper part of the walls,

together with the ceiling, at which it is considered disrespectful to look, are covered with handsome red damask, flowered over with gold, and tucked up about six feet high, so as to be removed from pilgrims' hands. The ceiling is upheld by three cross-beams, whose shapes appear under the arras; they rest upon the eastern and western walls, and are supported in the centre by three columns, about twenty inches in diameter, covered with carved and ornamented aloe wood. At the Freki corner there is a dwarf door, called *Bab el Taubah* ('of repentance'), leading into a narrow passage built for the staircase by which the servants ascend to the roof: it is never opened except for working purposes. The *Aswad* ('propitious') corner is occupied by a flat-topped and quadrant-shaped press or safe, in which at times is placed the key of the Kaabah. Both door and safe are of aloe wood. Between the columns, and about nine feet from the ground, run bars of a metal which I could not distinguish, and hanging to them were many lamps said to be of gold. This completes the upholding work of the hall.

The Kaabah is supposed to have been built and rebuilt ten times:—1. By angels, in obedience to the commands of Allah; 2. by Adam; 3. by Seth; 4. by Abraham and Ishmael; 5. by the Amalikah, descended from the great grandson of Ham, son of Noah; 6. By the Beni Turham, the children of Kahtan, fifth descendant from Noah; 7. By Kusay bin Kilab, governor of Mecca, and fifth forefather of the Prophet; 8. By certain Arab tribes, under the direction of Mohammed; 9. by Abdullah bin Zubayr, nephew of Ayesha, the wife of the Prophet, in A.H. 64; 10. by Hajjaj bin Yusuf, at the orders of Abd el Malik, in A.H. 74. Since then it has been frequently repaired, especially by the Abbassides and by the Sultan Murad Khan.

Many wonderful and miraculous legends are related in connection with this building. It is said that ravenous beasts will not approach it; nor will birds perch upon the house, except to be cured of sickness, for fear of defiling the roof. Though small, it will contain any number of devotees; and invalids recover health by rubbing themselves against the Kiswah and the Black Stone. A hundred thousand mercies descend upon it daily; and from whatever corner of it rain comes up, there is plenty in the lands that lie in that direction. (Burton, iii. 196.) But towards the end of time an Abyssinian host is prophesied to destroy it; though ages must elapse before that fatal event will take place.

KABOOL. [AFGHANISTAN.]

KABOOL, or CABOOL, a river in Afghanistan, which rises in the Oonna mountains, about lat. $34^{\circ} 20' N.$, and falls into the Indus, near Attock, after a course of about 340 miles. It is the only great affluent which the Indus receives from the W., and flows with extraordinary rapidity.

KABYLES. [ALGIERS.]

KAEMPFER, ENGELBRECHT, was born September 16, 1651, at Lenggo, in Westphalia. He passed through several schools, and finally studied medicine and natural science at the University of Cracow for three years, and at Königsberg for four years more. From Prussia he went to Sweden, where he solicited and obtained the place of secretary to an embassy which was then going to Persia. In 1684

the embassy arrived at Ispahan, then the capital of Persia. The information which Kaempfer collected during his travels and his residence in Persia is embodied in his 'Amœnitates Exoticæ.' When the embassy returned to Europe in 1685, Kaempfer entered as surgeon into the service of the Dutch East India Company, served in the Persian Gulf, and, sailing from Bender Abbassi, in 1689, for Batavia, visited most of the countries on the western shores of Hindustan. At Batavia he occupied himself chiefly with the natural history of the island of Java. In 1690 he went from Batavia to Japan, as physician to the embassy which the Dutch East India Company annually sent to the Japanese court. He remained at Nagasaki, in Japan, from September, 1690, to November, 1692, and during this time he accompanied two embassies to Yeddo. His observations on Siam and Japan are given in his great work entitled 'The History of Japan,' the original of which has never been published; but a translation was made from a copy in the possession of Sir Hans Sloane by J. G. Scheuchzer, and published in England in 2 vols. folio, 1727. Kaempfer returned from Japan to Batavia, which he left in 1693 for Amsterdam. In April, 1694, he took the degree of doctor of physic at the University of Leyden. On his return to his native place, he was appointed physician to his sovereign. He died November 2, 1716.

KEMPFERIA, a small genus of Indian *Scitamineæ*, or *Zingiberaceæ* of some authors, of which the species are indigenous to the islands of the Archipelago and the southern parts of the continent of India, as Bengal and the districts on its eastern frontier.

KAFFA, called also *Feodosia*, is a town built on the south-eastern shores of the Crimea, in $45^{\circ} 6' N.$ lat. and $85^{\circ} 20' E.$ long., on a wide open bay, which is more than twenty miles across. The town stands on the most western angle of this bay, and its harbour is protected by a projecting cape. In ancient times it was called *Theodosia*, and was included in the Greek kingdom of the Bosphorus. According to the author of the 'Periplus of the Euxine,' it was a Milesian colony.

In 1474 Kaffa was taken from the Genoese by the Turks, but still continued a considerable place, though its population had decreased from 80,000, which it had when the commerce of the Genoese was most flourishing, to 20,000 individuals. The wars which the Russians, in the latter half of the last century, carried on in these parts, ruined Kaffa, and still more the emigrations which took place when the Russians got possession of it in 1782. Towards the end of the last century Pallas describes it as a heap of ruins, inclosed by strong and lofty walls, which were fortified by towers, at the distance of 20, 40, and 60 fathoms from each other. In this ruined state the town remained up to the year 1806, when Russia declared it a free harbour. Fishing is the principal occupation of the inhabitants, who numbered, according to the last return, 8435. Grain and wool are the principal articles exported. The town contains many memorials of its former greatness.

KAFFA, a country in Eastern Africa, south of Abyssinia. The capital is Soonee, containing, according to the accounts of travellers, between 6000 and 7000 inhabitants, who call themselves Christians.

KAFFRARIA. [CAFFRARIA.]
KAFIRISTAN. [CAFRISTAN.]

KAGOSIMA, a town of Japan, in a deep bay at the south end of the island Kiusiu. It was bombarded by a British squadron on the 15th August, 1863, when it was burned, and its forts silenced, as a punishment for the murder of the British resident.

KAHIRA, or CAIRO, more properly *Al-Kahira*, which was its former name, but now called by the natives *Musr*, 'the victorious,' the capital of modern Egypt, is situated in $30^{\circ} 2' N.$ lat., and $31^{\circ} 15' E.$ long., between the eastern bank of the Nile and the ridge of Mokattam, and near the apex of the Delta of the Nile. Cairo occupies about three square miles. It is surrounded by a wall, the gates of which are shut at night, and is commanded by a large citadel situated at an angle of the town, on one of the lower elevations of the contiguous ridge, in which is the residence of the Pasha.

The open spaces in the city are few, and the greater number of the streets are so narrow that two laden camels can scarcely pass abreast, and in many there is hardly room for one. This arrangement excludes, as it was intended, the rays of the sun, and places the thoroughfares in shadow. In the cool of the evening the crowd is incessant, the variety of costumes striking, and the street cries are deafening and discordant.

In the neighbourhood of Cairo are Schoobra, with a country-house and fine gardens of the pasha; Abou Zabel, where are a school of medicine, anatomy, and surgery, and a large military hospital, all created by Mehemet Ali. Nearly opposite Cairo, on the left bank of the Nile, are the great pyramids of Ghizeh.

Cairo still maintains the reputation of being the best school of Arabic literature; and for Mohammedan theology and jurisprudence the fame of its professors remains unrivalled. There is a newly-founded museum for the collection of Egyptian antiquities.

The city of Cairo is the seat of government, and the residence of the viceroy, being also on the railroad from Alexandria to Suez. The population, including the suburbs of Boulak and Fostat, or Old Cairo, is estimated at 254,000, comprising Mohammedans, Copts, Jews, and numerous foreigners. The climate is healthy, and varies little, the mean temperature in the winter being $58^{\circ} 5'$, and in summer, $85^{\circ} 1'$ Fahrenheit. Rain falls ten or twelve times a year, but only lasts for one or two hours.

Beside the viceroy's palace, the citadel contains the arsenal, mint, public offices, and the magnificent new mosque of Mehemet Ali. The citadel itself is commanded by forts placed on the extremity of the chain of Mokattam, on the slopes of which Cairo is built.

A series of gardens and plantations separate the city proper from its suburbs—Boulac and Misr-el-Aatik. Cairo is divided into several distinct quarters, according to the religion and race of its inhabitants, as the Coptic quarter, the Jews' quarter, and the Frank or foreigners' quarter—all of which are separated by gates. Shepherd's Hotel, a large and well-conducted establishment, is the great resort of the English.

The edifices of Cairo comprise many of the finest remains of Arabian architecture, all dating from the

reign of the Arabs, and the ancient sultans of Egypt. Among them are about 400 mosques, with picturesque minarets, several of the ancient gates, an aqueduct for conveying water from the Nile to the citadel, the ancient works of the citadel itself, and the palace and well of Joseph. At Old Cairo are the seven towers, still called the Granary of Joseph, and serving their ancient purpose. In the island of Rhoda is the celebrated Nilometer, a graduated column for indicating the height of the water during the annual inundation of the river; on the south of the city, outside the walls, are the tombs of the Mamelukes, who were inveigled into the city by Mehemet Ali and indiscriminately massacred; and on the north-east the celebrated obelisk of Heliopolis, which is the oldest in the world, having been erected about a century before the arrival of Joseph in Egypt. Cairo is traversed by a canal for irrigation, which commences at Old Cairo. There is a branch railway of one mile to Boulak, the port of the city, and telegraphic lines connect it with Alexandria, Suez, and Damietta.

Cairo was long the chief *entrepôt* for the commerce of Egypt, and its trade has greatly increased since the opening of the railway to Alexandria and Suez. The bazaars are well supplied with goods of every description, and thronged with crowds of visitors of all nations: caravans arrive annually from Mourzook, Sennaar, and Darfur. There are four primary government schools, excellent schools conducted by the American missionaries, who also preach in Arabic, a museum of Egyptian antiquities, a magnetic observatory, hospitals, and a lunatic asylum. Two newspapers are published here—one in Turkish, and the other in Arabic.

Cairo was founded by the Arabs in 970; its citadel was built by Saladin in 1176; and it was the capital of the sultans of Egypt till the time of the Turkish conquest in 1507; since which it has been the residence of the pashas, governors of the province. It was taken by the French in 1798, and held by them for three and a half years.

(Lane's *Account of the Manners and Customs of the Modern Egyptians*; Martineau, *Experiences of Eastern Life*; A. W. Kinglake, *Eöthen*; Bartlett, *The Nile Boat*; Malte Brun, *Géographie Universelle*, &c.)

KAISARIYEH, or CÆSAREA, one of the most important cities in Asia Minor, situated in a plain to the north of the Erjish Dagh, in about $38^{\circ} 41' N.$ lat., $35^{\circ} 25' E.$ long., has a population variously estimated at from 25,000 to 50,000, consisting of Greeks, Turks, and Armenians. The streets are narrow and dirty, and the squares and market-places also abound with filth, and the naturally healthy climate is poisoned by the absence of all sanitary arrangements. The inhabitants are noted for their commercial enterprise, and the town is the *entrepôt* for a large extent of country. The bazaars are well supplied with European manufactured goods. The Armenians have a bishop and two churches, and the Greeks also have a church. Kaisariyeh is identical with the ancient Cæsarea, the capital of Cappadocia, originally called Mazaca, which name was changed to that of Cæsarea when Cappadocia became a Roman province.

KALE, the name given (1) to a species of cabbage,

the *Brassica oleracea* of botanists. This is the vegetable known to the kitchen gardener as Greens. It does not run to a heart, like the common cabbage, but is marked by the open head of its dark green or purplish-coloured leaves. The variety termed *German greens* is much used as a winter vegetable. From the close clustering form of the edges of its leaves it is sometimes named *Curly Greens*. (2) *Kale*, with a prefix, as *Sea-kale* (*Crambe maritima*), is another plant much used for the table. It is a native of the south of Europe, but is now extensively cultivated in Britain.

KALEIDOSCOPE, a name compounded of three Greek words (*kalos*, *eidōs*, and *skopos*), and denoting the exhibition of beautiful forms, is the designation of an optical instrument which was invented by Sir David Brewster, and made public in 1817.

The essential parts of the instrument consist of two plane mirrors of glass, having their posterior surfaces blackened in order to prevent any reflection of light from thence. Each mirror is from six to ten inches long, and of a trapezoidal form; the larger end about an inch and a half wide, and the shorter end about three-quarters of an inch; and the two are placed in contact with one another at the wide end of each, so as to form a dihedral angle, the like ends being placed together. The object to be viewed is disposed contiguously to the larger ends, and the eye should be near the opposite extremity, but a little above the line of contact. The effects produced by the reflections of the light may be understood from the following explanations:—

Let A C, B C, be the two extremities of the mirrors on the side farthest from the eye of the observer. These lines, and the sectoral space between them, will be visible by rays coming directly to the eye; and, at the same time, rays from the line A C falling at a certain angle of incidence on the mirror which passes through B C will, on being reflected from thence to the eye, give rise to the image C a of that line; in like manner rays from the line B C falling at an equal angle of incidence on the mirror passing through A C will, after reflection, give rise to the image C b of the line. These, with the intermediate rays, produce the first reflected sectors B C a and A C b. Other rays from the sector A C b at the surface of the mirror A C will fall on the mirror B C; and while a portion of them arrive at such angles of incidence as to be reflected to the eye and produce the perception of the sector a C b', another portion of them will be reflected back to the mirror A C at such angles of incidence as to be re-reflected

to the eye and cause the perception of the sector a' C b'. In a similar manner the rays first reflected from B C a will, by subsequent reflections, give rise to the perceptions of the sectors b C a', b' C a''.

Thus it is easy to perceive that an object, as M, on A C, with its immediately reflected image M', will give rise to the appearances of similar figures at m m', m'' m'''; and an object, as N, on A B, with its immediately reflected image N', will give rise to the appearances of similar figures at n n', n'' n''': also an object, as P, between A C and B C, will appear by reflection similarly situated in all the other sectors.

Sir David Brewster found means to obtain multiplied images of such objects as flowers, trees, and even persons or things in motion: and thus the importance of the instrument was greatly increased. Some kaleidoscopes have been executed in such a manner that the two mirrors may be placed at any required angle with one another; by which means the images in the visible field of view may be varied at pleasure. The instrument is capable also of being constructed so that the multiplied image may be projected on a screen, and thus made visible at one time to many spectators. Again, Dr. Roget has shown ('Annals of Philosophy') that the properties of the instrument may be greatly extended by employing, instead of two, three and even four plane mirrors, united together at their edges so as to form a hollow prism, or a frustum of a pyramid, the reflecting surfaces being towards the interior. These are called polycentral kaleidoscopes.

Sir David Brewster's account of his invention is contained in his 'Treatise on the Kaleidoscope,' Edinburgh, 1819, of which a new edition was published in 1860. The instrument is very useful to pattern-drawers and others, as it supplies them with an almost endless variety of suggestions.

KALENDAR, or **CALENDAR**, a register or distribution of the year, accommodated to the uses of life, containing the order of days, weeks, months, festivals, &c., as they occur in the course of the year. It is so called from the *kalendæ*, or kalends, which among the Romans denoted the first day of every month. The kalendar being of civil institution, varies according to the different distributions of time in different countries. Those which we shall take more particular notice of are the Roman, the Julian, the Gregorian, and the Reformed Kalendars: a slight mention of the others will be sufficient.

Romulus, according to tradition, formed what is deemed the original Roman kalendar, by which the year was divided into ten months only, consisting of an unequal number of days, and began with March. The total number of days was 304. It was, however, soon discovered that the civil year, as thus constituted, was much shorter than the solar year. Romulus therefore added two intercalary months to every year; but these months were not inserted in the kalendar, nor were any names assigned to them until the following reign. Some Roman antiquaries maintained that the old kalendar continued in use till the time of Tarquinius Priscus.

Numa, in imitation of the Greeks, divided the year into twelve months, according to the course of the moon, consisting in all of 354 days: according

to Pliny ('Hist. Nat.,' xxxiv. 7), he afterwards added one day more to make the number odd, which was thought a more fortunate number. But as ten days, five hours, forty-nine minutes were wanting to make the lunar year correspond to the course of the sun, he intercalated every other year an extraordinary month, called *Mensis Intercalaris*, or *Mercedonicus*, between the 23rd and 24th of February. This month appears to have consisted alternately of twenty-two and twenty-three days during periods of twenty-two years, the last biennium in the twenty-two years being entirely passed over.

Julius Cæsar, when he had made himself master of the state, resolved to put an end to this disorder, by abolishing the use of the intercalations, and for that purpose, B.C. 47, adjusted the year according to the course of the sun, and assigned to the months the number of days which they still contain. He also added an intercalary day to February every four years. To make everything proceed regularly, from the 1st of the ensuing January, he inserted in the current year, besides the intercalary month of twenty-three days, which fell into it, two extraordinary months between November and December, the one of thirty-three, the other of thirty-four days; so that this year, which was called the last year of *confusion*, consisted of fifteen months, or 445 days. These sixty-seven days were inserted in order to set the year right, which was sixty-seven days in advance of the true time.

All this was effected by the care and skill of Sosigenes, an astronomer of Alexandria, whom Cæsar had brought to Rome for that purpose; and a new kalendar was formed from his arrangement by Flavius, digested according to the order of the Roman festivals, and the old manner of computing the days by kalends, nones, and ides, which was published and authorized by the dictator's edict.

This is the *Julian* or Solar year, which continues in use to this day in all Christian countries, without any other variation than that of the *old* and *new style*, which was occasioned by a regulation of Pope Gregory XIII., in 1582, who, observing that the vernal equinox, which at the time of the council of Nice, in 325, had been on the 21st of March, then happened on the 10th, by the advice of astronomers caused ten days to be thrown out of the current year, between the 4th and 15th of October; and to make the civil year for the future to agree with the real one, or with the annual revolution of the earth round the sun, or, as it was then expressed, with the annual motion of the sun in the ecliptic, which is completed in the 365 days, 5 hours, 49 minutes, he ordained that every 100th year should not be leap year, excepting the 400th.

This alteration of the style was immediately adopted in all Catholic countries; but not in Great Britain till the year 1752, when eleven days were dropped between the 2nd and 14th of September, so that this month contained only nineteen days; and thenceforth the new or reformed style was adopted, as it had been before in the other countries of Europe. The same year also another alteration was made in England, by which the legal year, which before had begun on the 25th of March, began upon the 1st of January; this alteration first took place on the 1st of January, 1752. (See the

Statute 24 Geo. II. c. 23.) By this statute the whole Gregorian kalendar was adopted.

Of the three parts into which the Romans divided their month, the *kalenda*, or kalends, are noticed at the commencement of this article. They were so called (a *calando* vel *vocando*) from the pontifex calling out to the people that it was new moon. The fifth day of the month was called *Nonæ*, the nones, and the thirteenth, *Idus*, the ides, from the verb *iduarè*, to divide; because the ides nearly divided the month. The nones, from *nonus*, the ninth, were so called because, counting inclusively, they were nine days from the ides. In March, May, July, and October, the nones fell on the 7th, and the ides on the 15th of the month. The mode of fixing any particular day was by saying that it was so many days before the kalends, nones, or ides, next immediately following. Thus the 28th of April was the fourth day before the kalends of March; the 4th of March was the fourth day before the nones of March; and the ninth of March was the seventh day before the ides of March.

The Attic year consisted of twelve lunar months of 30 and 29 days alternately; an intercalary month of 29 or 30 days was inserted every two years; but as this was $7\frac{1}{2}$ days too much, the intercalary month was sometimes omitted. The full Attic month consisted of 30 days, and was divided into three decades.

KALENDAR, REVOLUTIONARY. A Report was made to the National Convention, 6th October, 1793, on the new Kalendar by Fabre d'Eglantine; and a decree was passed on 4 Frimaire (24th November, 1793) for the establishment of the new Kalendar. The Committee of Public Instruction was commissioned to cause the new Kalendar to be printed in various forms, with plain instructions for its use. The instructions ('Instruction sur l'Ere de la République,' &c.) were drawn up by Romme. The Republican Kalendar is explained in a French work, in its sixth edition: 'Concordance des Calendriers Républicain et Grégorien,' Paris (6me édition), 1812, 8vo.

The year was to begin at the midnight of Paris Observatory which precedes the true autumnal equinox. It was to consist of 365 days, with 12 months of 30 days each (the 30 days being three decades of 10 days each), and 5 complementary days, which were called *sansculotides* (a name afterwards repealed). A sixth complementary day was to be added, according to the words of the decree, 'selon que la position de l'équinoxe le comporte;' which adds, 'the period of four years, at the end of which this addition of a day is ordinarily necessary, is called the *Franciade*,' (Art. 10 of the Decree; and the remarks of Romme in the 'Instruction,' &c., s. iii., 'De la Longueur de l'Année.' The first year of the French Republic began at midnight, the 22nd September, 1792. The second year began on the 22nd, 1793, at midnight (Art. 5 & 6 of the Decree). The Gregorian reckoning was restored from and after January 1, 1806, by an imperial ordonnance, dated 22 Fructidor, An XIII. (September 9, 1805).

Though every period of four years was a *Franciade*, and the last year of the *Franciade* was called *Seatile* (having six complementary days), yet in fact An IV., An VIII., &c., are not leap years. The following list is actually made from the work above mentioned:—

		Sept.	
An I.	begins	22,	1792
II.	"	22,	1793
Sext. III.	"	22,	1794
IV.	"	23,	1795
V.	"	22,	1796
VI.	"	22,	1797
Sext. VII.	"	22,	1798
VIII.	"	23,	1799
IX.	"	23,	1800
X.	"	23,	1801
Sext. XI.	"	23,	1802
XII.	"	24,	1803
XIII.	"	23,	1804
XIV.	"	23,	1805

When the Gregorian year is not leap year, the beginnings of the months are as follows, according as the republican year begins on September 22, 23, or 24:—

1 Vendémiaire	is Sept.	22,	23,	24.
1 Brumaire	is Oct.	22,	23,	24.
1 Frimaire	is Nov.	21,	22,	23.
1 Nivose	is Dec.	21,	22,	23.
1 Pluviose	is Jan.	20,	21,	22.
1 Ventose	is Feb.	19,	20,	21.
1 Germinal	is March	21,	22,	23.
1 Floréal	is April	20,	21,	22.
1 Prairial	is May	20,	21,	22.
1 Messidor	is June	19,	20,	21.
1 Thermidor	is July	19,	20,	21.
1 Fructidor	is Aug.	18,	19,	20.

But when the Gregorian year is leap year, the beginnings of the months are as follows, according as the republican year begins on September 22, 23, or 24:—

1 Vendémiaire	is Sept.	22,	23,	24.
1 Brumaire	is Oct.	22,	23,	24.
1 Frimaire	is Nov.	21,	22,	23.
1 Nivose	is Dec.	21,	22,	23.
1 Pluviose	is Jan.	20,	21,	22.
1 Ventose	is Feb.	19,	20,	21.
1 Germinal	is March	20,	21,	22.
1 Floréal	is April	19,	20,	21.
1 Prairial	is May	19,	20,	21.
1 Messidor	is June	18,	19,	20.
1 Thermidor	is July	18,	19,	20.
1 Fructidor	is Aug.	17,	18,	19.

For instance, what is 14 Floréal, An XII? The republican year begins September 24, 1803, so Floréal falls in 1804, which is Gregorian leap year. Look at the third Table; and when the year begins September 24, the first of Floréal is April 21: consequently the 14th is May 4, 1804.

KALGUEV, or KOLGUEV, is a considerable island in the Arctic Ocean, in the Russian government of Archangel, and situated to the north of the peninsula of Schemonkonski. It lies between 68° and 69° 40' N. lat., and 47° 30' and 48° 10' E. long., and is about 66 miles in diameter. The surface is undulating; it has some low mountains, which rise in the centre, two small rivers, and several brooks of fresh water. The cliffs are covered with an incredible number of sea-birds; the interior is full of polar bears, foxes, &c. Except a few Samoides there are no settled inhabitants. It is resorted to every

summer by traders from the mainland, who procure here large quantities of skins, eggs, and feathers.

KALHARI, or KALIHARI DESERT, is a vast tract of southern Africa, between lat. 20° 30' and 28° S.; long. 18° 30' and 26° E. It is partly inhabited by the Bosjesmans, whose hair grows like short thick bristles—a peculiarity which is considered to mark the greatest specific difference between any of the races of mankind. Rain rarely falls in this district, and no water is to be had except at a few springs or 'sucking places,' which the miserable natives who wander over it in search of game carefully conceal. Little of the interior is known, but its eastern side has been skirted by Dr. Livingstone. In many places it is well wooded, and largely covered with thorn trees.

KALI, an Arabic word, signifying the ashes which remain after the combustion of vegetable substances. Hence the word *alkali*.

KALISZ, Province. [POLAND.]

KALMIA, a genus of plants belonging to the natural order *Iricaceæ*. *K. latifolia* is a native of N. America from Canada to North Carolina, on the sides of stony hills. The leaves and flowers of this genus are poisonous, and the honey of bees which collect the juice is injurious. *K. angustifolia*, Haulm-leaved Kalmia, is a native of North America from Canada to the Carolinas, in bogs and swamps, and sometimes in dry mountain lands. It is a shrub one or eight feet in height, with dark red flowers. It is called Sheep-laurel in North America, because it is supposed to be very injurious to sheep; and the partridge is said to become poisonous as food after feeding on it.

KALMUCKS. [MONGOLIA.]

KALONG. [CHEIROPTERA.]

KALUGA, a government of European Russia, lying between 53° 24' and 55° 21' N. lat., 33° 20' and 37° E. long., is bounded W. and N.W. by Smolensk, N.E. by Moscow, E. by Tula, and S. by Orel. The area measures 11,022 square miles; and the population at the last census was 1,007,471. The surface is level, but here and there broken by a low hill or the wooded banks of the numerous rivers that flow through it. Forests cover about half the area, the arable lands about one-third. The soil for the most part is sandy clay. The Oka and its numerous feeders are the principal rivers. There are lakes and marshes in the centre and west of the government. The rivers, several of which are navigable for barges, or available for floating timber, are frozen from November to March. The soil of Kaluga being generally poor requires abundance of manure: the chief products are rye, oats, barley, wheat, hemp, lint, and flax. Barely enough for the consumption is produced. Horned cattle are scarce, but the horses are excellent. Horticulture is carefully attended to. The mineral products are bog iron, mill-stones, lime, gypsum, and turf. There are several great iron forges. The manufactures comprise metallic goods and cutlery, cotton, leather, beet-root sugar, soap, and distilling. The commerce is principally with Archangel. Oil and spirits are exported. Sail-cloth is made both for the European and American market, and coloured cloths for the China trade. *Kaluga*, the capital of the government, is situated in 54° 30' N. lat., and 36° 5' E. long., on the Oka, and has 32,335

inhabitants. It is surrounded with a rampart converted into a public walk. The streets are narrow, and for the most part consist of wooden houses. The best buildings are the bishop's palace, the residence of the governor, and the principal church. There are manufactures of muskets, cloth, oil, paper, cotton, pottery, soap, and vitriol, tanneries and sugar refineries; and a good trade is carried on in corn, sheep-skins, Russian leather, and wax. Kaluga has long been a place of banishment for political offenders.

KAMES, HENRY HOME, LORD, an eminent Scotch lawyer and author, was the son of a well-descended country gentleman of reduced circumstances. After receiving his early education under a private tutor, he studied civil law and jurisprudence at the University of Edinburgh. In 1723 he was called to the bar, where his industry and natural powers soon raised him into repute as a successful pleader. After a brilliant and laborious career he was appointed, in 1752, one of the judges of the Court of Session by the title of Lord Kames. In 1763 he was nominated a lord of justiciary in the Scotch Supreme Criminal Court. Three years later he came into possession, by right of his wife, of the fine estate of Blair-Drummond, and with characteristic ardour devoted himself to the development of its resources. He died at the advanced age of eighty-seven, on the 27th of December, 1782.

Lord Kames was not only a fortunate lawyer and a successful judge, but a writer of eminence on critical and metaphysical subjects. His mind was active, keen, and discriminative, and these qualities are conspicuous in all his works. Those which now preserve his fame, and are still appreciated by the philosophical student, are the 'Art of Thinking,' first published in 1761, and the 'Elements of Criticism,' produced in the following year. Both these books are distinguished by clearness of judgment and ingenuity of thought.

KAMI, a Japanese title applied to any deified hero or saint, and to the deceased mikados or spiritual sovereigns. The number of the Kamis is unlimited, and their functions are widely different. Some preside over the elements; some over the forces and phenomena of nature. Their worship is called *Kami-ro-mitsi*, or the 'Way of the Kami.'

KAMPTULICON. [FLOOR CLOTH.]

KAMPEN. [OVERSSEL.]

KAMTCHATKA, a peninsula projecting from the north-eastern parts of Asia into the Pacific, in a direction nearly due south, lies between 51° and 59° 55' N. lat., and between 155° and 165° E. long. Its length is above 800 miles, and its width varies between 30 and 200 miles. The interior of the peninsula is generally rugged. A mountain range running east of the river Kamtchatka is distinguished by several high summits, which are of volcanic origin, and most of them still active. One of these summits, the Plutchevsky, is 16,000 feet above the sea-level. The mountains approach close to the eastern coast, which is composed of high rocks, rugged cliffs, and bold promontories, forming numerous inlets, the entrances to which are blocked up by reefs of rocks. The western shore, along the Sea of Okhotsk, is very low and sandy. The best part of the peninsula is the vale of the Kamtchatka River, which towards its southern extremity is 40 miles across, but grows narrower as it proceeds northward. Its length is

180 miles. Its soil is deep and rich, composed of a black earth, and exhibits a considerable degree of fertility. The Kamtchatka River, about 250 miles long, is the only important one in the peninsula.

The climate of Kamtchatka, when compared with that of Europe under the same latitude, is very severe. Winter generally lasts nine months, and frost is common even in summer. During the winter a great deal of snow falls. In the interior, where protected by the mountains, the climate is milder; the larch tree, and rye, barley, buckwheat, potatoes, white cabbages, turnips, radishes, and cucumbers are grown. The number of horses and cattle is on the increase; but the most valuable animal in the peninsula is the dog, which is a kind of half-breed between the mastiff and the wolf, and has the peculiarity of never barking. They are tractable to their masters, but are not so much won by kindness as by restrained authority. They cheerfully work hard, and draw the sledges for days and even weeks together with very little food. The natives formerly lived chiefly on the produce of the chase; but since the number of wild animals has considerably decreased, fishing is more attended to. Fish is very abundant on the coasts. The forests contain many fine timber trees, which are little used, but might be employed in shipbuilding. The mineral wealth is little known: in some places there is iron ore, and sulphur in immense beds is found in the vicinity of the volcanoes.

Two native tribes inhabit the peninsula, the Kamtchadales in the south and the Koriakes in the north. The Kamtchadales are short, but stout, and broad in the shoulders, with large heads, flat and broad faces, prominent cheek-bones, thin lips, lank black hair, and eyes deeply sunk in the head. They evidently belong to the Mongol race. The Koriakes are principally distinguished from them by the smallness of their head. Both nations differ in language and in mode of life. The Kamtchadales are hunters and fishermen; while the Koriakes are a wandering tribe, subsisting on the produce of their numerous herds of reindeer. The population is estimated at 6000.

The export of goods is carried on in sledges, the principal articles of commerce being sable, fox, and other skins (about 30,000 annually), whale oil, fish, and eggs. The trade is chiefly with Okhotsk, and the imports consist mainly of colonial goods.

The principal towns are PETROPAULOVSKI, Nishnei, Kamtchatka, and Bolcheresk; but their population and commerce are very inconsiderable.

Kamtchatka is a Russian province annexed to a government of Eastern Siberia, called the Maritime Region. It was discovered and conquered by the Russians between 1696 and 1706, and is now subdivided into four districts, each under a lieutenant-governor.

KANAGAWA is the name of the principal seaport of Japan, on the island of Nippon, in the bay of, and 15 miles S. from, Jeddo, of which city it is the port. It is a long narrow town stretching for nearly three miles along the bay, and having only one main street. The population is about 8000. The houses are built chiefly of wood, and the shops are large and well supplied. The shores of the bay are very beautiful and covered with villages, while the view inland is bounded by the cone of the large mountain Fusi-yama. Kanagawa was opened to commerce in 1858, and now has a larger foreign

trade than any other Japanese port; the ships mostly owned by British, American, French, and Dutch merchants. The number of vessels which entered in 1867 was 254 (174,030 tons), and the clearances 248 (164,812 tons); 134 of these were British. The value of the exports in the same year was 9,708,907 dollars. The principal articles are raw silk, tea, silk worms' eggs and cocoons, tobacco, galls, seaweed, cuttlefish, mushrooms, medicines, ginseng, rags, and raw cotton. The imports were valued at 13,008,785 dollars, and consisted chiefly of cotton and woollen manufactures, arms, lead, iron, tin, leather, ivory, and sugar. The consuls reside at the native town of *Yokohama*, on the opposite side of the bay, which has 12,000 inhabitants.

KANGAROO (*Macropus*), the name of a genus of marsupial or pouched animals. They are for the most part natives of Australia. The members of this family group (*Macropodidae*) are characterized by the young being born in a very rudimentary state. At birth, they are received into a pouch placed on the belly of the mother. The hind legs of the kangaroo are long and powerful, while the fore legs are very short, causing the animal to pass from place to place by a series of jumps. The anterior parts of the body are small and slender when compared with the posterior. It has a small head, long ears, cleft upper lip, six incisor teeth in the upper jaw, and only two in the lower. The fore feet have five toes, the hind feet only four, and the tail is very long and strong. In addition to the larger kangaroos (*Macropus*), the family contains also the tree kangaroos (*Dendrolegus*), and the kangaroo rats (*Hypsiprymnus*).

KANSAS, one of the United States of North America, admitted into the Federal Union in 1861, extends from 37° to 40° N. lat., and from 94° to 107° W. long. Its length is 400, and its breadth 208 miles, the area being 78,418 square miles. It is separated from Utah by the territory of Colorado and the Rocky mountains, and watered by the Kansas, Missouri, and Arkansas rivers, the first of which rises in the Rocky mountains, flows in an easterly direction 900 miles to the Missouri, and is navigable to Fort Riley. The climate generally throughout the state is very fine. The soil is very fertile, producing all the cereals, with cotton, hemp, tobacco, and fruits. It is one of the finest grazing states in the west, and the farms are well stocked with cattle. The prairies contain an abundance of game, including the buffalo, deer, antelope, wild turkey, wild goose, and prairie hen. Coal, gypsum, quartz, porphyry, limestone, sandstone, and lead are among the minerals.

Kansas is well supplied with religious and educational institutions; has a Senate of twenty-five members, a House of Representatives of seventy-five members, and sends one member to Congress. The population in 1860 was 107,206; in 1867 it had increased to 135,000 whites, 15,000 free coloured, and 8180 Indians; total, 158,180.

The state is divided into forty-five counties; the principal towns are *Topeka*, the capital, on the S. side of the Kansas River, which is handsomely laid out with streets 130 feet wide, and has a population of 2500. *Leavenworth*, the largest city, is situated on the Missouri River, and contains seventeen churches, numerous schools, printing-offices, steam

saw-mills, flour-mills, and breweries. It is the headquarters for supplying stores to the western forts, and also of an immense trade with the territories. Population, 18,000. There is an important military fort in the vicinity. *Atchison*, on the Missouri, is a place of considerable trade, and has 3500 inhabitants. *Lawrence* is a fast rising town, with a population of 3500. It suffered severely during the civil war in 1863. The other towns are *Manhattan*, *Wyandot*, and *Emporia*. Kansas was formed into a territory in 1854, and was the scene of bitter struggles between the advocates and opponents of slavery. The constitution under which it was admitted into the Union prohibited slavery.

KANT, IMMANUEL, was born April 22, 1724, at Königsberg, in Prussia, where he lived all his life. He died there on the 12th of February, 1804. He received his early education at the gymnasium, whence he removed in 1748 to the university, to attend the classes of philosophy, mathematics, and theology. In 1755 he commenced a series of private lectures on logic and metaphysics, physics, and mathematics, which he continued to give for fifteen years, until he was invited, in 1770, to fill the chair of logic and metaphysics, which he held until 1794.

When Kant first entered upon philosophical studies, nothing but superficial eclecticism and uncompromising dogmatism prevailed on the one hand, and on the other an unlimited scepticism, which was cherished by the refined irony of Hume. To put an end to this state of things, which was as dangerous to morality and religion as subversive of the legitimacy of knowledge, was the object of Kant's labours. He accordingly proceeded to an examination of man's cognitive faculty, in order to discover the laws and extent of its operation. This investigation he designated the Criticism of the Pure Reason, and he maintained that the reason, as a pure faculty, must criticise not only itself, but also the subordinate faculties of sense and understanding. Kant understood by *pure* whatever is independent of experience, as opposed to the empirical, which rests upon it. The pure, or whatever in knowledge expresses the universal and necessary, is *à priori*, that is, antecedent to experience; whereas all that is contingent, or only comparatively general, is *à posteriori*. The first requisite in philosophy is a science which may establish a possibility, and determine the principles and extent of such knowledge, which must have its root in the pure reason itself, and cannot be the ground of the contingent and empirical; for the pure reason contains nothing except the formal or necessary principles of all knowledge, whereas the objects to which these principles refer are given to the mind from without. As an instance of these universal and necessary principles, Kant adduces the law of causation. The notion of a cause implies the necessity of its being connected with some effect, and enforces so strongly the universality of this law, that it is inconsistent with the derivation of it from the repeated association of an effect with an antecedent. The next point which Kant notices, in the Introduction to the Analysis of the Pure Reason, is the distinction between analytical and synthetical judgments. The analytical are those in which the predicate is connected with the subject by identity; the synthetical are devoid of all identity of the subject and predicate

Analytical judgments may be also termed explanatory, the synthetical may be called extending judgments; since in the analytical the predicate adds nothing to the notion of the subject, and only resolves the notion which forms the subject into its constituent and subordinate notions, which are contained in it: whereas in the synthetical a new element is added by the predicate to those already contained in the subject, which was not previously understood in it, and therefore would not result from it by any analysis. For instance, the proposition that all bodies are extended is analytical; but the assertion that all bodies are heavy is synthetical. All the conclusions of experience are synthetical. Experience proves the possibility of the synthesis of the predicate 'heavy' with the subject 'body'; for these two notions, although neither is contained in the other, are nevertheless parts of a whole, or of experience, which is itself a synthetical combination of its intuitions, although they only belong to each other contingently.

Transcendental logic is divided into analytic and dialectic, of which the former is the critic ('Der Kritik'), or investigation of the understanding, as the faculty of notions; the latter, of the reason, as the faculty of ideas.

The criticism of the transcendental dialectic gives this result—that the ideas of the reason, as pure speculative ideas, are nothing more than simple conceptions, for which no corresponding object can be scientifically shown to exist. Accordingly, neither the existence of God, nor the immortality of the soul, nor the freedom of the will, can be demonstratively established. Nevertheless the reason is not merely a theoretical, but also a practical faculty, which gives the law of human conduct and action. Now, these laws present themselves with such unconditional necessity (the *categorical imperative*), that no rational man can refuse obedience to them; and on the other hand, without the freedom of the will these laws could not be obeyed; and without God and the soul's immortality there would be no final cause or motive for human conduct, which must be placed in a state of felicity, agreeable to morality, provided by and to be obtained through God, in another and a better life. Consequently every man who is conscious of his moral destination holds these practical ideas to be both true and objectively legitimate, notwithstanding that he is compelled or required to admit them merely by a subjective ground—the testimony of his own consciousness, and of the moral wants resulting from its dictates. This Kant calls the postulate of the practical reason. The acceptance of this postulate as true and legitimate does not constitute a scientific certainty, or knowledge properly, which indeed does not exist for the supersensible; it is merely a belief. This faith or belief, however, is thus distinguished from every other, that it is a moral or practical faith, and consequently possesses for the believer all the certainty requisite for the guidance and conduct of life, and consequently it enjoys a subjective certainty and authority. This faith is the proper foundation of religion, which is nothing else than a conscientious observance of all duties as divine commands, since God, as the moral lawgiver, cannot be worthily honoured otherwise than by obedience to the laws of morality.

VOL. VIII.

The most important of the works of Kant in a philosophical sense are the 'Kritik der reinen Vernunft,' 7 vols., Leipzig, 1828; 'Kritik der praktischen Vernunft,' 6th edit., Leipzig, 1827; and the 'Kritik der Urtheilskraft,' 3rd edit., Berlin, 1827. (Masson's *Recent British Philosophy*.)

KANTURK. [CORK.]

KAOLIN, the Chinese name for *porcelain clay*. It occurs massive and disseminated in disintegrating granite rocks, and is generally supposed to be derived from the decomposition of the felspar which they contain. Its colour is either white, yellowish, or reddish-white. Fracture fine earthy; soft, dull, and opaque; adheres to the tongue; specific gravity 2.216; infusible. Kaolin is found in China, France, Saxony, &c.; and in England a large tract of this substance occurs near St. Austell, in Cornwall, on the south side of the granite range. It contains crystals of felspar, quartz, and mica. From this source the porcelain manufactory of Worcester is supplied. Analysis: Silica, 46.8; alumina, 37.3; potash, 2.5; peroxide of iron, 0.4; water, 13.0.

KARPHOLITE (Gr. *karphe*, 'to shrivel,' and *lithos*, 'a stone'), a mineral of a straw colour, which occurs in minute crystals and silky fibres. It is sufficiently hard to scratch fluor-spar, although it may be scratched by felspar. Its specific gravity is 2.93; and its constituents—silica, 36.15; alumina, 28.70; water, 10.78; oxide of manganese, 19.16; oxide of iron, 2.29; fluoric acid, 1.47; lime, 0.27.

KARS is a city in Asiatic Turkey, the capital of a pashalic, situate 105 miles N.E. of Erzeroum, and containing about 12,000 inhabitants. It is partly walled, and has eight mosques, minarets, Armenian churches and convents. It was taken by the Turks in 1853, and afterwards, in 1854, besieged by the Russians, who only succeeded in recapturing the place after a brave and memorable resistance on the part of the Turks, commanded by an English general named Sir William Williams, and General Knety, a Hungarian. At the treaty of Paris, in 1856, Kars was evacuated by the Russians, and restored to the dominion of the Porte. The town has an active transit trade.

KARSHI, a large town in Bokhara, on the Shebri Sebz river, 90 miles S.E. of Bokhara. It has extensive manufactures of knives, which are exported to all parts of Central Asia, as well as to Persia, Arabia, and even to Turkey. Some of them are of beautiful workmanship, and are quite equal in durability and temper to the best made in Sheffield. Karshi has a population of about 25,000; and it cannot fail to become a very important place when the trade of Central Asia is developed.

KASAN or KAZAN. [CASAN.]

KASHMIR. [CASHMERE.]

KATER, HENRY, an English mathematician of some eminence, was born at Bristol, April 16, 1777. He became a captain in the army, and for several years devoted himself to ascertaining the precise length of the seconds' pendulum—an object of high importance in physical science. He was the first who availed himself of the convertibility of the points of suspension and oscillation for the determination of the exact length of a mathematical pendulum vibrating in the same time as a given pendulum.

But his name will be transmitted to posterity in

C

connection chiefly with his invention of the floating collimator, an instrument which has conferred on practical science essential benefits, its object being the determination of the position of the line of collimation in the telescope attached to an astronomical circle. After a life spent in philosophical research, Kater died in London, April 26, 1835.

KATHETOMETER, or **CATHETOMETER**, an instrument for measuring difference of levels, as between two liquid columns in equilibrium. It consists of a small telescope, sliding vertically upon an upright scale, and furnished with cross wires; the point of intersection of the latter is made to coincide with the apex of one of the liquid columns, and the position of the telescope upon the scale is then read off. A similar process is adopted for the second column, and the difference between the two readings exhibits the difference in vertical height.

KATRINE, or **CATERAN**, **LOCH**, a lake in the county of Perth, Scotland, 5 miles E. of Loch Lomond. It is deep, of a serpentine form—10 miles long and 2 broad—and surrounded by lofty mountains, the most striking of which is Benvenue. The surplus waters of the lake are discharged at its E. end through the Pass of the Trosachs and Loch Achray, into the river Teith: and Glasgow is supplied with water from it by magnificent aqueducts opened by Her Majesty in 1859. The distance from Loch Katrine to Glasgow is upwards of 25 miles.

KATTIMUNDOO, sometimes spelt **CUTTIMUNDOO**, is the juice of the plant *Euphorbia nereifolia*, extensively grown in India. This juice is procured by making incisions in the bark, or sometimes it exudes as a natural gum. When solidified it resembles gutta-percha, and is used in India for similar purposes, but it has not yet become an article of export.

KEAN, CHARLES, son of the celebrated tragedian, Edmund Kean (see next article), was born on the 18th of January, 1811, and educated at Eton. Adopting the stage as a profession, he made his appearance at Drury Lane in 1827 as 'Young Norval.' The only occasion upon which he and his father appeared together in London was at Covent Garden, March 28, 1833, in 'Othello;' Miss Ellen Tree—whom the son married, January 29, 1842—performing the part of 'Desdemona.' He afterwards made a tour in America. Returning to London, he appeared as 'Hamlet,' on the 8th of January, 1838. Thenceforward he was known as one of the first tragedians of his time; and he acquired additional celebrity by the elaborate and tasteful production of the masterpieces of Shakspeare, &c., under his management of the Princess' Theatre. On his retirement from this post, he was presented at a banquet with a splendid testimonial, the duke of Newcastle presiding, and Mr. Gladstone taking part in the proceedings. He afterwards undertook a professional tour in Australia. His death, took place on the 23rd of January, 1868.

KEAN, EDMUND, was born about 1787, in London. His father, Edmund Kean, seems to have been a stage-carpenter, and his mother, Miss Ann Carey, was an actress at minor theatres and with strolling players, and in showmen's booths. Little attention seems to have been paid to his instruction by any one, but his theatrical education commenced

early. His mother took him with her in her rambles with strolling players and showmen. Master Carey, as he was then called, was so clever, that once, when Miss Carey was performing at Windsor, he was required to give his recitations before George III. at the Castle, which he did, to his majesty's great delight, and was dismissed with a handsome present.

Kean's first performance of a complete character was that of young Norval, in 'Douglas,' in the booth of Richardson of Bartholomew Fair notoriety; his first engagement with a regular company was in 1804, when he made his appearance at Sheerness on Easter Monday, on which occasion he played George Barnwell and Harlequin in a pantomime. From this time till 1814, when he made his first appearance at Drury Lane Theatre, London, his life was a series of the vicissitudes, struggles, and privations incident to the profession of an actor in country theatres. In November, 1813, while acting at Dorchester, he was seen and appreciated by Mr. Arnold, manager of Drury Lane Theatre, who engaged him for three years, at a salary of eight, nine, and ten pounds per week, respectively. This occasioned a contest with Mr. Elliston, then manager of the Olympic Theatre, who alleged that he had made a previous engagement with him. A delay was caused by the claim, highly distressing to Kean, who was in extreme poverty, but at length Mr. Arnold ventured to complete his bargain, and the play-bills of Drury Lane announced 'The Merchant of Venice,' 'Shylock by Mr. Kean, from the Exeter Theatre.' There had been no previous puffing, and the house was thinly attended, but the applause was tumultuous: he repeated the character; the house was well filled, and his fame was thenceforth established. Mr. Whitbread, on the part of the Drury Lane Committee, cancelled the original agreement and concluded a new engagement, by which he received a weekly salary of 20*l.* per week. Not long afterwards the committee made him a present of 500*l.*, and many valuable gifts from individuals rewarded his surprising talents.

Kean's career of success, including a visit to America in 1820, was uninterrupted till January, 1825, when the action of Cox *v.* Kean was tried, and a verdict of 800*l.* damages was pronounced against him for adultery with the alderman's wife. The public were exasperated against him; he was driven from the stage of Drury Lane, and afterwards from that of Edinburgh, and then availed himself of an invitation to pay a second visit to America.

After an absence of two seasons in the United States, Kean returned to London, having during the time not only acquired but saved a considerable sum. He had, however, now fallen into habits of almost constant intoxication; his constitution was broken up, his memory impaired to such a degree that he could not study a new part, his alacrity of spirit was gone, and his performances were little more than a faint reflection of what they had been. Kean quarrelled with and discarded his son Charles, whom he had sent to Eton College, for wishing to become an actor; but they afterwards became reconciled, and in 1833 it was announced that Kean would play Othello, at Covent Garden Theatre, with his son Charles as Iago. Kean struggled through the part as far as the speech 'Villain, be sure,' when his

head sunk on his son's shoulder; he was borne off the stage, and his acting was at an end. He lingered for a while, but died May 15, 1833.

Kean in his person was small, but well formed; his face was thin, but handsome; his eyes and hair were black; his countenance, in variety and intensity of expression, was wonderful; his voice, in its upper tones, was somewhat harsh, in its lower tones it was soft and melodious; his action was free, graceful, varied, and appropriate; his conception of character was original and true, and evidently the result of observation and deep and careful study. He did not, as some have supposed, trust to the impulse of his feelings. He studied his characters much and anxiously. Frequently, after his family were retired to rest, he would act scene after scene before the pier-glass, endeavouring to produce, by expression of countenance, gesture, emphasis, and modulation of voice, the effect which his conception of the character required. The *Life of Kean*, by F. W. Hawkins, from original sources, was published in 1869.

KEANE, RIGHT. HON. LORD JOHN, G.C.B., was born in 1781. In 1809 he served in the campaign of Martinique, and was present at the siege of Dessaix. In 1812, being then a full colonel, and lieutenant-colonel in the 60th Foot, he was sent to Madrid, where his reputation was such that he was intrusted with the command of a brigade in the third division, and served with it until the end of the war with France, in 1814, in the battles of Vittoria, the Pyrenees, Nivelle, Orthes, Toulouse, &c. In 1814 he attained the rank of major-general, and was rewarded with the Egyptian medal and other decorative honours. In the year 1833 he was appointed commander-in-chief of the army in Bengal; and in 1838 he succeeded Sir Henry Fane in the command of the forces operating in Scinde, and the north-western parts of India. He was now engaged in conducting the operations of a considerable army, with important objects to attain. The difficulties and successes which attended the British troops under his command, and the memorable victory of Ghuznee, are well-known matters of history. [HINDUSTAN; AFGHANISTAN; SCINDE.] In 1839, on the termination of this campaign, he was raised to the peerage, with a pension of 2000*l.* a year for his own life, and that of his two immediate successors. He died in 1844.

KEATS, JOHN, an English poet, was born in Moorfields, London, in the year 1796. He received a classical education at Enfield, under the father of Mr. Cowden Clarke, and was afterwards apprenticed to a surgeon. In 1817 he published a volume containing his juvenile essays at verse, and shortly afterwards his long poem, 'Endymion,' which called forth a virulent attack from the *Quarterly Review*; an attack which, according to the evidence of his friends Byron and Shelley, embittered his existence. Keats, whose health had been impaired by his attentions to a dying brother, resolved, as a last resource, to try the climate of Italy, his friend Severn, the artist, accompanying him. They went first to Naples, then to Rome, where, after some weeks of intense agony, he died, February 24th, 1821, having previously published a third volume of poems, containing 'Lamia,' 'Isabella,' 'The Eve of St. Agnes,' 'Hyperion,' 'Odes to the Nightingale,' and the

'Grecian Urn.' The English pilgrim may see his grave and Shelley's in close proximity. The 'Life and Letters of John Keats,' edited by Lord Houghton, gives a painfully interesting picture of the poet in his latter days, sinking under the effects of consumption and a hopeless attachment which had contributed to undermine his health. Keats' first sonnets were published in the *Examiner*, then edited by Mr. Leigh Hunt; his 'Endymion' was dedicated to the memory of Chatterton.

His poetry is exceedingly rich and graceful, and its imagery, often classic in character, is always beautiful, if sometimes too luxuriant. He died, however, before the promise of his youthful genius could be fulfilled; and what he might have been can only be inferred from the severe simplicity and exquisite polish of his 'Hyperion.'

KEBLE, JOHN, M.A., vicar of Hursley, near Winchester; author of 'The Christian Year,' born about 1800; received his later education at Oxford, where he became a member of Oriel, examiner *in literis humanioribus*, and in 1831 professor of poetry, an office which he retained until 1842. In 1827 he published 'The Christian Year: thoughts in verse for the Sundays and holidays throughout the year,' which has had a very extensive popularity. It was followed by a work which had Christian childhood for its theme, 'Lyra Innocentium: thoughts in verse for Christian children, their ways and their privileges.' In 1844 some of the fruits of Mr. Keble's activity as professor of poetry at Oxford were given to the world in two volumes, entitled 'De Poeticæ vi medicæ: Prelectiones Academicæ Oxoniæ habitæ annis, 1832-41,' published, as they had been delivered, in Latin. To the 'Tracts for the Times,' 1834-36, he contributed his disquisition on 'Primitive Traditions.' With Dr. Pusey and John Henry Newman he edited the 'Library of Fathers of the Holy Catholic Church anterior to the division of the East and West, translated by members of the English Church,' the publication of which was commenced at Oxford in 1838. Mr. Keble died on the 29th of March, 1866. A memoir of him, by his friend Sir J. T. Coleridge, was published in 1868; and the Keble College, specially intended for a 'poor and clerical college,' and the first founded at Oxford since 1714, was erected in 1869 as the best memorial that could be devised for the much-loved author of the 'Christian Year.'

KEEL (Dutch, *Kiel*), is the lowest timber of a ship, upon which the whole fabric is raised. It extends from one end to the other, and for a large ship consists of two or more pieces of wood scarfed together at the extremities, and is usually protected by strong iron binding.

The keelson passes inside the vessel, from stem to stern, as the keel does outside, to which it is united by bolts which go through both, and through the floor timbers. In large ships two additional keelsons about 30 feet long are bolted to the floor timbers, sufficiently near to one another that the foot of the mainmast may rest upon them. They serve to relieve the bottom of the ship from the pressure of that mast, and strengthen it against the upward action of the water. The word seems to have anciently signified a complete *ship*, and we read of the sea-rovers invading England in *caels* or *keels*.

KEELAGE. A charge paid for a ship on coming into port.

KEEPS, in the feudal ages, strong towers in the middle of any fortification, to which the besieged resorted in the last extremity. They were similar to what the classical ancients called the citadel, or inner fort, a term which is still applied to modern fortification. [CASTLE.]

KEIGHLEY. [YORKSHIRE.]

KEITH. [BANFFSHIRE.]

KEITH, GEORGE. The family of Keith is one of the most ancient and historical in Scotland. The office of the king's marischal was attached to the lands of Keith in East Lothian; and in 1305 Sir Robert of Keith, hereditary marischal of Scotland, was justiciary of Scotland from the Forth to the Mouth, and sat in the English council at Westminster as a Scotch representative. He commanded the Scotch cavalry at Bannockburn, and afterwards married a relative of Bruce. Through this alliance the Keiths acquired large estates in Kincardineshire, and, by purchase, the sea-girt rock of Dunnottar, where they built a castle, which they made their chief seat. The family was ennobled about 1458, and the fourth earl nearly doubled his domains by marriage with the heiress of Inverugie, and was reputed the wealthiest peer in Scotland. These vast possessions passed to George, the fifth Earl Marischal, and founder of Marischal College, Aberdeen, who succeeded his grandfather in 1581; his father having died in the previous year.

The subject of our biography was educated at King's College, Aberdeen, where he distinguished himself by his great proficiency in the classics, Hebrew, history, and antiquities; and at Geneva, under the celebrated Beza, who instructed him in theology and eloquence. In 1589 he was sent to Denmark with proposals from King James for the hand of the Princess Anne. In 1609 he was appointed lord high commissioner in the Scottish Parliament. His memory has been perpetuated mainly by his enlightened munificence displayed in the establishment of Marischal College. The charter, dated 2nd April, 1593, provides for the maintenance of a principal, three professors, and six bursars. Since that time several additional chairs and bursaries have been established; and by an Act of Parliament passed in 1858, Marischal College and King's College have been incorporated into one university. The earl died in 1623.

KEITH, GEORGE, tenth Earl Marischal, eldest son of the ninth earl, was born about 1693, and succeeded his father in 1712. He was attainted for his share in the rebellion of 1715, and with his brother escaped to the Continent. After many hardships and long wanderings, he found refuge at the court of Prussia, and was appointed by Frederick the Great ambassador to the court of France, and afterwards to Madrid. While at the latter court he revealed to Mr. Pitt an important secret respecting the family compact of the princes of the house of Bourbon. This procured his pardon in 1759, and he revisited Scotland, but in a few years returned to Prussia, where he died in 1778, in the eighty-sixth year of his age. The title became extinct at his death. His brother James, who had risen to the rank of field-marshal in the Prussian service, closed a brilliant military career at

the battle of Hochkirchen, fought between the Prussians and Austrians on the 14th of October, 1758. King Frederick celebrated the virtues of his friend in a poetical epistle.

KEITH, GEORGE ELPHINSTONE KEITH, VISCOUNT, a distinguished naval officer, was born in 1746, and was the fifth son of Charles, tenth Lord Elphinstone, and Clementina, only child of the sixth earl of Wigton, and niece and heir-of-line to the last Earl Marischal. He served in the American war, in the war with France, and in 1799 succeeded Earl St. Vincent as commander of the Mediterranean fleet. The most brilliant of his exploits was the famous landing at Aboukir, the success of which was due to his promptitude and skill. In 1797 he was created an Irish peer by the title of Baron Keith, of Stonehaven-Marischal; and in 1803 a peer of the United Kingdom, as Lord Keith, of Banheath. He died 10th March, 1823. By his first wife he left a daughter, the Viscountess Keith, and wife of the well-known count de Flahault, formerly French ambassador at the court of London. His second wife was the daughter of Henry Thrale, M.P. for Southwark, and friend of Dr. Johnson.

The present earl of Kintore is also descended from the family of Keith.

KELLS. [MEATH.]

KELLERMANN, FRANÇOIS CHRISTOPHE, DUC DE VALMY, Marshal of France, and one of the most distinguished of Bonaparte's generals, was born at Strasbourg, May 30, 1735. He entered the Conflans legion when seventeen years of age, and in 1788 rose to the rank of quarter-master-general. The French revolution opened a new field for his military career. In 1792 he became general-in-chief of the army of Moselle, and in November of the same year commander-in-chief of the army of the Alps and Italy. He was principally employed at the head of the cavalry, of which he became inspector-general in 1798. In June, 1799, he was sent to command the French troops in the Batavian republic. Returning to France he followed the fortunes of Napoleon, was with the army of reserve in 1804-6, and accompanied Bonaparte to the Rhine and into Germany. He was created a marshal of France upon the occasion of Napoleon's becoming emperor, in May, 1804. Kellermann, after the Restoration, joined the Bourbons, and was created a peer of France, and honoured with the grand cross of St. Louis in August, 1814. He died at Paris, September 12, 1820, and was buried in Père la Chaise.

KELP, the produce of sea-weed when burned, from which carbonate of soda is obtained. It was formerly much used in the manufacture of glass and soap, and large quantities of iodine are now obtained from the residue, after the carbonate of soda is separated. For soap and bottle glass a cheaper and better alkali is now made from common salt. [ASHES; SODIUM.]

KELSO. [ROXBURGHSHIRE.]

KEMBLE, CHARLES, a member of an illustrious family, was born at Brecknock, on the 25th November, 1775. He was educated at the Roman Catholic college of Douay. In 1792 he obtained a situation in the post office; but so strong was his predilection for the stage, that he soon threw up his employment; and after a few appearances at private

theatres, made his debut in public at Sheffield, as Orlando in 'As You Like It.' In 1794 he obtained an engagement at Drury Lane, and in 1797, at the Haymarket.

With the single exception of Garrick, Charles Kemble played successfully, for a lengthened period, the widest range of character of any actor of the age. His Macduff, Aufidius, Cassio, Laertes, Alcibiades, Henry V., Antony, and Orestes, were true personifications of historic character, as represented by a majestic form, an impressive countenance, and a full-toned, commanding voice. But Kemble did not confine himself to mere acting. He engaged in dramatic authorship, and was also the compiler of several adaptations.

For a short period he was the manager of Covent Garden Theatre; and in 1840 he accepted the office of examiner of plays, having closed his career as an actor on the 20th of April of the same year. He died on the 12th November, 1854. He left one son and two daughters, Fanny and Adelaide. His son, Mr. JOHN MITCHELL KEMBLE, was the author of the 'Saxons in England,' and distinguished as one of the chief Anglo-Saxon scholars and historians of the age. For many years he was editor of the *British and Foreign Quarterly Review*, and held the office of examiner of plays, under the lord chamberlain. He died in 1857. ADELAIDE KEMBLE obtained reputation as a singer, and marrying an Italian nobleman, settled in Italy. FANNY KEMBLE (Mrs. Butler) has won distinction as an actress and a Shakspearian reader, while as a dramatist, a poet, and an agreeable writer, her productions have been favourably received by the public.

KEMBLE, JOHN PHILIP, elder brother of Charles, was born February 1, 1757, at Prescott, in Lancashire. His father, Mr. Roger Kemble, was an actor and manager of a provincial theatrical company. He was educated partly at the Roman Catholic seminary of Sedgley Park, in Staffordshire, and afterwards at the English college at Douay, in France, whence at the age of nineteen he returned to England, and made his appearance in the character of Theodosius, in the tragedy of that name, at Wolverhampton, January 8, 1776. Two years afterwards he was a regular member of the York company. On Tuesday, 30th of September, 1783, Mr. Kemble made his first appearance in London at Drury Lane, in Hamlet. In 1790 he became manager of that theatre. In 1803 he purchased for 24,000*l.* a sixth share in Covent Garden Theatre from Mr. Lewis, and became manager of that establishment. In 1808 Covent Garden was destroyed by fire; and on the opening of the new theatre in 1809, under Mr. Kemble's management, an advance in the prices of admission to the pit and boxes gave rise to the well-known O. P. (Old Prices) riots, during which the tragedian was personally and grossly insulted whenever he appeared upon the stage. On June 23, 1817, he took his leave of the London audience, and soon afterwards retired to the south of France, finally taking up his residence at Lausanne, in Switzerland where he died, February 26, 1823, aged sixty-six. Mr. Kemble's talents, both as an actor and a manager, were of a very high order; his fine taste and classical acquirements being perceptible in every effort. In society he was the accomplished gentleman as

well as the convivial companion, and to the last enjoyed the respect and regard of the noblest and wisest in the land.

KEMPIS, THOMAS A, born in 1380 at Kempen, near Cologne, was a regular canon of the monastery of Mount St. Agnes, where he applied himself to transcribing the Bible and other religious books. He afterwards began a collection of pious and ascetic treatises, among which were the four books 'De Imitatione Christi,' which have been erroneously ascribed to him as his own composition, but which he merely transcribed. The authorship of the work is generally attributed to John Gerson, chancellor of the University of Paris, who died in 1429. Thomas à Kempis composed some ascetic treatises, such as 'Dialogus Novitiorum de Contemptu Mundi,' &c., but they are inferior to the book, 'The Imitation of Christ,' which, next to the Bible itself, is supposed to have had the largest number of readers of which sacred literature, ancient or modern, can furnish an example. It has been translated into almost every language, and has gone through hundreds of editions. Dean Milman says, 'In it is gathered and concentrated all that is elevating, passionate, and profoundly pious in all the older mystics.' With the exception of the fourth book, which relates to the real presence in the Eucharist, it has been used indiscriminately by all bodies of Christians. Thomas à Kempis died in 1471, aged ninety-one. A new translation of this noble work under the title of 'Like unto Christ,' has recently been published in England.

KEMPTEN (the ancient *Campodunum*), a town of Bavaria, situated on the river Iller, in the circle of Swabia, 55 miles S.W. of Augsburg. It is built in the old-fashioned style, and consists of two parts—the *Stifts-stadt*, or St.-Hildegard, which stands on a hill; and the ancient free imperial city, which is in the valley. The old town is walled, and nearly encircled by the new. Kempen has a castle, two churches, a public library, a Latin school, a gymnasium, an hospital, and an orphan asylum. There are manufactures of woollen, cotton, and linen goods, and considerable trade in furs, wool, salt, linen, &c. The population in 1861 was 10,370.

KENDAL. [WESTMORELAND.]

KENILWORTH. [WARWICKSHIRE.]

KENNEBECK. [MAINE.]

KENNET, River. [BERKSHIRE.]

KENNICOTT, BENJAMIN, was born of humble parents at Totness in Devonshire, April 4, 1718. In 1744 some friends raised a sum of money to enable him to go to Oxford. He entered at Wadham College, and applied himself with the greatest diligence to the study of divinity and Hebrew. He resided at Oxford till the time of his death, September 18, 1783. He was a canon of Christ Church, and librarian of the Radcliffe Library, to which office he was appointed in 1767.

The most celebrated of Kennicott's works is his edition of the 'Hebrew Bible,' which was published at Oxford in 2 vols. folio, the first volume in 1776, and the second in 1780. In 1753 Dr. Kennicott published a work 'On the State of the Printed Hebrew Text of the Old Testament,' which was succeeded by another volume on the same subject in 1759.

KENSINGTON GARDENS, one of the public ornamental parks of London, lie on the west side of

Hyde Park, to which they form an excellent adjunct, though quite distinct in character. Intended only for the pedestrian, they are conspicuous for presenting one immense and almost continuous mass of shade, beneath the noble avenues and clumps of fine old trees. King William III. bought the gardens, which at that time only occupied 26 acres, adjoining a palace known as Kensington House. Queen Anne enlarged them to 56 acres, and Queen Caroline to their present extent, by taking 300 acres out of Hyde Park, and forming the Serpentine out of a series of ponds.

A magnificent monument, in memory of the late lamented Prince Consort, was erected during the years 1866-68, on the south side of Kensington Gardens. The funds were partly raised by public subscription, and partly voted by the House of Commons. In Kensington Palace, a plain and irregular building of red brick, William III. and his queen, Queen Anne, and George II. breathed their last, and there her majesty Queen Victoria was born.

KENT, a maritime county of England, is bounded N. by the estuary of the river Thames, E. by the German Ocean and the Straits of Dover, S. by Sussex, and W. by Surrey. A detached portion of the parish of Woolwich in Kent, about 400 acres, lies on the north side of the Thames. The greatest length of the county from E. to W. is about 64 miles; the greatest breadth, N. to S., is about 40 miles. The area is 1624 square miles, or 1,039,419 acres, of which above 720,000 are meadow and arable land, and a considerable quantity of the residue is woodland. The total population of the county at the census in 1861 was 733,887—369,129 males, and 364,758 females, being an increase of 118,121, or 19 per cent. on the census of 1851. According to an official estimate of the Registrar-General, it had still further increased to 825,284 in 1868.

Kent is divided into twenty-eight poor law unions and twenty-five county courts. There are two regiments of yeomanry cavalry, and about fifty companies of volunteer rifles and artillery in the county.

Coast-line, Islands, &c.—The northern part of the county, along the estuary of the Thames, is skirted by a line of marshes, which are very extensive near the junction of the Thames and the Medway, forming a portion of the Isle of Grain. Eastward of this island lies the Isle of Sheppey, extending about 10 miles by 5, the surface of which is laid down for the most part in grass, but the upland part on the northern side produces good corn. The marshes terminate east of the Swale, and the coast again rises to some height in clayey cliffs, which extend past Herne Bay and Reculver nearly to the Isle of Thanet. In this isle, which occupies the north-eastern corner of the county, and was formerly separated from it by the Stour, the chalk cliffs commence, and continue along the whole line of coast to Pegwell Bay, which is the boundary of the isle to the south-east. The North Foreland is a projection of the Isle of Thanet, due east of Margate. The chalk cliffs of the so-called island are succeeded by the low shore of Pegwell Bay, which continues to Walmer Castle near Deal. Here the chalk cliffs recommence, and continue round the South Foreland to Sandgate, presenting many lofty heights near Dover. From Sandgate the coast begins to decline until it forms

the extensive tract of Romney Marsh, which ends on the borders of Sussex, at Winchelsea. Opposite Deal lie the GOODWIN SANDS, the channel between which and the Kentish coast forms the well-known roadstead of the Downs.

The Downs, which are about 8 miles in length and 6 in width, and vary in depth from 4 to 12 fathoms, are a safe anchorage in most winds, and are the general rendezvous of shipping leaving the Thames for the Channel, or returning homeward. To the north of the Downs are 'The Small Downs,' a smaller roadstead immediately contiguous to the Downs properly so called. The name is derived from the *dunes*, or sand-heaps of the Goodwins and the shore.

Surface and Geology.—Kent is on the whole a hilly county. The chalk range of the North Downs enters it on the west side from Surrey, and runs nearly east through the county, being cut by the valleys of the Darent, the Medway, and the Stour. Many of its hills rise from 400 to 600 feet in height; and the range terminates on the coast between Folkestone and Walmer, where it forms a mass of white cliff, the 'white walls of Albion.'

The district between the chalk and the estuary of the Thames is, for the most part, occupied by the plastic clay, which immediately overlies the chalk, and is again overlaid by the London clay in the isles of Grain and of Sheppey, in the shore near Reculver, and in other parts of the county, including Shooter's Hill.

South of the North Downs the chalk marl and greensand crop out, and cover a belt of land which skirts the chalk throughout the whole extent of the county from west to east. South of this belt lies another occupied by the Weald clay, about 5 miles in width; and this is bounded on the south by a belt of Hastings sand. The Weald of Kent was anciently an immense forest (the ancient Andredes-weald), inhabited only by deer and hogs. The greater part of it has, however, been gradually cleared and brought into cultivation, though it is still interspersed with numerous oak woods and groves of beech.

Hydrography and Communications.—The northern boundary is formed by the Thames, to the basin of which nearly the whole county belongs. The other principal rivers are the Ravensbourne, the Darent, and the Medway, which flow into the Thames; and the Stour and the Rother, which flow into the sea. The lengths of the rivers are about as follows:—The Ravensbourne, 10 miles; Darent, 20; Cray, 9; Medway, 60; Eden, 16; Teise, 17; Beult, 20; Stour, 45. The Medway is by far the most important of these; it rises near East Grinstead, and flows past Penshurst, Tunbridge, Yalding, Maidstone, Rochester, and Chatham, to the Thames at Sheerness. The tide flows up to Maidstone Bridge. Ships and large vessels cannot ascend above Rochester Bridge. Below Rochester the estuary gradually expands to a considerable width, and forms an important harbour for the British navy. Numerous arms of the river or creeks penetrate the marshes, which spread inland to a considerable extent from the banks of the river. As high as Rochester it is under the conservancy of commissioners. Its upper course embraces a succession of beautiful scenery. The Stour has its rise in the chalk-hills; it flows N.N.E. past Canterbury, where it becomes navigable, and in the lower part of

its course divides into two branches, the Greater and the Lesser Stour. A branch, anciently called the Wantsum, separated the Isle of Thanet from the rest of the county, but has long ceased to have a distinct channel. The waters of the Lesser Stour have been employed for purposes of irrigation, and hence this branch is no longer navigable, but small craft ascend the Greater Stour as high as Canterbury. The former falls into the estuary of the Thames at Reculver, the latter into the English Channel at Pegwell Bay.

The principal canal in Kent is the Royal Military Canal, which was formed rather for the purposes of defence than of commerce, during the alarm of invasion in the war against Napoleon. It has, however, since been converted to commercial use. It runs from Oxney to Hythe. The Thames and Medway Canal is now the property of the South-Eastern Railway Company, who have filled up the section from Higham to Rochester, and which is now used for the transit of trains in a tunnel upwards of 2 miles in length.

Kent has a most abundant steam traffic from Ramsgate, Margate, Sheerness, Gravesend, Greenhithe, Erith, Woolwich, and Greenwich, to London; from Rochester to Sheerness; from Dover to Ostend, Calais, and Boulogne; and from Folkestone to Boulogne.

The South-Eastern, North Kent, and the London, Chatham, and Dover railways, with their branches, traverse the county.

Climate and Agriculture.—The climate of Kent is in general mild and genial. The soil may be divided into the gravel, chalk, and clay, which produce, where they mix in due proportions, an extremely fertile loam. The alluvial soils along the Thames and Medway, and in Romney Marsh, produce some of the richest marsh pastures in the kingdom.

Throughout the whole county the clay may be said to predominate, and the mode of cultivation generally adopted is that which suits the strongest soils. On the hills, however, chalk and gravel are the main ingredients of the surface soil.

The products of Kent are more varied than those of any other British county, and, owing to the drier climate, generally superior in quality. Wheat, barley, and other grains, turnips, clover, &c., are of the finest growth. The county also produces several crops which are peculiar to it, such as canary and radish seed, which grow chiefly in the Isle of Thanet, where there are few hedge-rows to harbour birds. Other seeds are likewise raised for the London seedsmen, such as spinach, cresses, and white mustard. Kidney beans are cultivated to a considerable extent in the neighbourhood of Sandwich, and from ten to twenty bushels per acre are produced. Woad and madder were formerly more commonly cultivated in Kent than they are now; the foreign, being raised at a less expense, has driven the Kentish out of the market.

There is comparatively but a small proportion of grass land in Kent, if we except the sheep downs on the chalk hills and the marshes. The latter produce most of the hay consumed in winter. Romney Marsh, which is well known for the richness of its grass, contains about 44,000 acres; on the borders of the Stour are 27,000; and along the Medway, Thames, and Swale, about 11,500 more, on which a great number of sheep are reared and fattened. The Romney breed is noted for its long wool.

There are very few dairies of any consequence in Kent, and no cheese is made, except for domestic consumption.

Hops are grown to a very great extent in this county, and with the exception of those which are raised at Farnham in Surrey, are the most esteemed of any in England. Nearly 40,000 acres are appropriated to them, supplying almost one-half of the whole crop of England. The finest are cultivated in the parish of East Farleigh, near Maidstone.

In that part of Kent which is nearest to London there are many extensive gardens; and about Deptford hundreds of acres are laid out in asparagus beds. Great quantities of peas are cultivated on the line of road from London to Rochester; and apples, pears, plums, and cherries are grown in extensive orchards for the supply of the London markets. The cultivation of filberts is peculiar to Kent, and carried on with peculiar success in the neighbourhood of Maidstone.

Throughout the county agriculture is in an advanced state. The estates are small, owing to the Saxon custom of gavel-kind, which is still maintained here, and by which the lands of a father dying intestate are divided among all the sons alike.

There are several important paper factories on the Darent and the Medway, as well as corn, oil, silk-printing, and gunpowder mills in the county, and shipbuilding is extensively carried on on the seaboard. There are no less than four royal dockyards in the county, viz., Deptford, Woolwich, Chatham, and Sheerness.

There are still some extensive woods in Kent, but they are diminishing every year; and the produce of bark and timber is much reduced from its ancient amount. The demand for hop poles has caused more attention to be paid to underwood; and some of the coppices which are well managed give a sufficient return to prevent their being grubbed up and converted into arable land.

Divisions, Towns, &c.—Kent is divided into five lathes, sixty-five hundreds, and 423 parishes. Each lathe comprehends several hundreds, and other smaller divisions. The lathes are—*Sutton-at-Hone Lathe, Aylesford Lathe, Scray Lathe, St. Augustine Lathe, and Shepway Lathe.*

There are several parts of the county which have their particular 'liberties,' exempt from the jurisdiction of the county magistrates. They are as follows:—1. The county of the city of Canterbury. 2. The city of Rochester. 3. The borough of Maidstone. 4. The liberty of Romney Marsh, which is under the jurisdiction of its own bailiff and jurors. 5. The liberty of the Cinque Ports, which is partly in Kent and partly in Sussex. [CINQUE PORTS.] For ecclesiastical purposes the whole county is in the diocese of Canterbury, except the city, archdeaconry, and deanery of Rochester. It is in the Home Circuit, except certain parishes near London, which, in criminal matters, are within the jurisdiction of the Central Criminal Court. The assizes are held at Maidstone. For parliamentary purposes the county is divided, by the Reform Act of 1867, into East, West, and Mid Kent, each returning two members to the House of Commons; in addition to which the cities of Canterbury and Rochester, and the boroughs of Dover, Greenwich, Maidstone, and Sandwich each

return two members; and Chatham, Hythe, and the newly-formed borough of Gravesend, one each; total, twenty-one.

There are sixteen polling-places. Canterbury is the place of election for the eastern division, Blackheath for the western, and Maidstone for Mid Kent. The amount assessed to the property tax is 2,555,500*l*.

The following are the principal places, with the population of each in 1861:—

Ashford, a market town, is situated on the west bank of the Stour, 12½ miles S.S.W. from Canterbury, and 67 miles from London. The South-Eastern Railway has a station here, and a large factory for the construction and repair of carriages and engines, by which the trade of the town has been greatly increased. There is a market-house in the centre of the town. The church has a Perpendicular tower, erected in the reign of Edward IV., when the church itself was repaired, if not rebuilt. Population of the town, 5522; of the parish 6950.

Aylesford (*Eghwys-ford*, or 'church-ford'), situated on the east bank of the Medway, 2½ miles N.W. from Maidstone. There is an ancient church with a square west tower. Population of the parish, 2057. Close to the Medway, a short distance west from Aylesford, stood a Carmelite friary, which was suppressed at the Reformation. Many portions of the conventual buildings are incorporated in the present mansion of the earl of Aylesford. On the side of the hill, about 1½ mile E.N.E. from Aylesford, is Kit's Coty House, one of those Druidical monuments called cromlechs. [CROMLECH:] Two stones placed upright, each 8 feet above the ground, 8 feet long, and 2 feet thick, form the sides; another upright stone, 5 feet high, 5 feet broad, and 14 inches thick, closes one end, the other end being left open; a fourth stone, 12 feet long, 9½ feet broad, and 2½ feet thick, forms a flat cover like a roof, sloping towards the closed end. All the stones are very rude and irregular. This cromlech is supposed to mark the burial-place of Catigern, who was killed in battle between the Britons and Saxons in 455.

Broadstairs, a small but fashionable bathing-place on the east coast of the Isle of Thanet, 2 miles north-east of Ramsgate, has a station on the London, Chatham, and Dover Railway. It was formerly called *Bradstowe*, and is included in the parish of St. Peter (Thanet), which has a population of 2855.

Bromley, a market town, is situated above the east bank of the Ravensbourne, 10 miles S.E. from London. It is a flourishing town, with a market-house near the centre, recently rebuilt. There are here two railway stations, some good inns, and a large number of villas and first-class mansions. The church has a low tower at the west end, massy and embattled. The entrance to Bromley church-yard affords a specimen of the ancient *lich-gate*, where the corpse rested before it was borne into the burying-ground. Dr. Hawkesworth, author of the 'Adventurer,' lies buried here. Population of the parish, 5505. It is a polling place for the county, and the head of a poor-law union.

Canterbury. [CANTERBURY.]

Chatham, a market town, parliamentary borough, and arsenal, is situated on the south-east bank of the estuary of the Medway, a short distance east from Rochester, with which it is connected by a continuous line of houses. Chatham is 33 miles E. by S.

from London by railway. It was a comparatively insignificant place till after the commencement, about 1757, of the great naval and military establishments, although it had a dockyard and arsenal founded as early as the reign of Elizabeth. The establishments now consist of the largest dockyard in the kingdom, which has numerous wet docks and building slips for vessels of the largest class; an extensive arsenal; barracks on a large scale for artillery and the royal engineers—the latter of whom have their headquarters here; infantry and marines; a park of artillery; large magazines and store-houses; besides a handsome dock-chapel, and habitations for the civilians who are employed. There is a school for engineers, established in 1812, and near the dock-yard gate is a large naval hospital. Population of the town, 25,183; of the parliamentary borough, 86,177: number of electors in 1869, 4293.

The river Medway widens here, and is flanked on the east and south by heights partly built on, and crowned with several forts and batteries. The principal buildings are six churches, ten chapels, a seamen's hospital, and soldiers' and mechanics' institute. The military and naval arsenals are separated from the town and the country beyond by a line of fortifications. Near the dockyard is a large prison for convicts, who labour in the yard. Fort Pitt is now used as a military hospital, and Fort Clarence as a military prison. The borough has no municipal jurisdiction, but sends one member to the House of Commons. Chatham gave the title of earl to the elder Pitt. The towns of *Brompton* and *New Brompton*, in the parishes of Chatham and Gillingham, with a population of 14,000, are partially inclosed within the line of Chatham fortifications.

Cranbrook, a market town, 48 miles S.E. from London, is irregularly built. The church is a handsome structure in the Perpendicular style, with buttresses and fine windows. Some woollen manufactures are carried on in Cranbrook, which is 7 miles S.S.W. of the Staplehurst station on the South-Eastern Railway, and 13 from Maidstone. Population of the parish 4128.

Crayford is a small place on the Cray, 8 miles E.S.E. of Greenwich, having an area of 2474 acres, and a population of 3103. In its vicinity are bleaching grounds, silk and calico printing establishments, and numerous chalk-pits. Here, in 457, Hengist totally defeated Vortimer in the second great battle between the Saxons and the Britons.

Dartford, a market town, 15 miles E. by S. from London Bridge, is situated in a narrow valley on the river Darent, about 3 miles from its junction with the Thames. There are several corn, paper, oil, and powder-mills in the neighbourhood. This important agricultural town is on the line of the North Kent Railway, and has a workhouse and market-hall, with a steam-engine factory, and an active trade with London by the river. The first paper-mill was built here by Spielman, who died in 1607. Here also are the ruins of a nunnery of the time of Edward III., and many ancient caverns dug in the chalk. Wat Tyler's insurrection broke out at Dartford in 1381. The town is governed by a local board of health. Population of the parish, 6597.

Deal, a market town, municipal and parliamentary borough and port, is situated on the coast, 74 miles

E.S.E. of London. It is annexed to Sandwich as a member of the Cinque Ports, and unites with that place in returning two members to the House of Commons: number of electors (1869) 1849. The town of Lower Deal extends a considerable way along the shore; Upper Deal, the most ancient part, is further inland. There is a pier, opened in 1864, but no harbour. The fine roadstead called the Downs extends in front of Deal between the shore and the Goodwin Sands; and the Deal fishermen, as well as the pilots, whose services were formerly in great requisition, have the highest reputation for skill and intrepidity. At the south end of the town is Deal Castle, erected by Henry VIII., in a good state of repair; and a little more than a mile farther south stands Walmer Castle, the residence of the Lord Warden of the Cinque Ports, with a modern house, and handsome grounds and garden. Here the duke of Wellington, and more recently the late Lord Palmerston, spent a portion of each year during the time they held the office of lord warden. The former died here on 14th September, 1852. The borough of Deal is divided into two wards, and is governed by six aldermen and eighteen councillors. Population of the parish, 7531. The principal industry of Deal is connected with maritime pursuits, but the occupation of its redoubtable boatmen has been much interfered with of late years, in consequence of the employment of steam-tugs to expedite outward and inward bound vessels, and also because the mails from foreign countries are now landed at other places more convenient for transmission to London. The number of vessels which entered the port in 1867, principally coastwise, was 259 (17,293 tons), and the clearances in the same year were 87 (5407 tons). The customs revenue received at the port in 1868 was 3139*l*.

Deptford is a naval port, separated from Greenwich by the Ravensbourne, near its junction with the Thames, and on the London and Greenwich Railway, 3 miles S.E. from London. It includes two parishes, St. Paul and St. Nicholas, adjoins Greenwich, and contributes with that place and Woolwich to return two members to Parliament. The borough was created by the Reform Act of 1832. There are two hospitals for decayed pilots and shipmasters or their widows, belonging to the Trinity House; an extensive victualling yard, where the provisions for the royal navy are manufactured or stored; and a dockyard, established by Henry VIII., and occupying an area of 31 acres, in which the ships of the royal navy were formerly built and repaired; it was closed as a government establishment in 1869. There are several private shipbuilding yards. A small part of Deptford is in Surrey. Evelyn, the author of the 'Sylvia,' lived here, and Peter the Great worked as a shipwright in its dockyard. The total population is 45,973.

Dover, a municipal and parliamentary borough, and Cinque Port, 70 miles E.S.E. from London, and 15 miles S.E. from Canterbury, is situated on the coast, in a narrow valley between two high ranges of chalk hills, which are broken through, and form lofty precipices in front of the sea on each side of the town, and on the south side rise perpendicularly above the houses and close behind them. On the east side, about a mile distant, is Shakspeare Cliff, 400 feet

high; and on the west side near the town is Dover Castle, with its irregular lines of fortification on the brow of the cliff, and its numerous galleries excavated far below in the chalk rock. The Castle Cliff is 325 feet above the sea, but the heights are much loftier. The castle is a collection of formidable works, occupying 35 acres, containing Roman and Saxon towers, a keep forming a bomb-proof magazine, and barracks for 2000 men. The town extends some distance up the valley, and stretches out on each side as far round as the cliffs will allow. The Dour, a small but clear stream, flows through the valley and falls into the harbour. The old town is irregularly built, and without any pretension to architectural effect, either in the streets or public buildings. The tower of St. Mary's church is of early Norman architecture, and another old church has also some Norman features. Of late years the town has been much improved, and become the resort of fashionable visitors. There are, on the north side, handsome crescents, parades, and terraces. It is the chief packet-station for the opposite ports of France, and the prosperity of the place depends in a great measure on the intercourse between England and the Continent. The imports consist mainly of eggs, fruit, and other rural produce from France, and there is also a thriving coasting trade and fishery. The number of vessels registered as belonging to the port in 1868 was 58 (4075 tons). The entries in 1867 were 2092 (282,148 tons), and the clearances 1304 (168,295 tons). The customs duties received at the port in 1868 amounted to 13,580*l*. The harbour consists of three basins, the outer one inclosed between two piers 150 feet apart. The first section of the admiralty pier, thrown out 1200 feet in 1864, renders the harbour always open. Dover is the terminus of the London, Chatham, and Dover Railway, and there is also an extension of the South-Eastern line from Folkestone, entering the town on the west by a tunnel cut in the Shakspeare Cliffs. The port is 21 miles from Cape Gris-nez, on the opposite side of the English Channel, and 26½ N.W. of Calais, with which it communicates by a submarine telegraph. There is also submarine communication with Ostend. The harbour of refuge, when completed, will inclose 574 acres. Fortifications of immense strength have been erected on the heights commanding the town. Shipbuilding, sail, rope, and paper making are the chief branches of industry which occupy the population. Dover is the seat of quarter sessions, has a board for licensing pilots, and a court of the constable of the Cinque Ports is held here. The municipal borough is divided into three wards, and is governed by six aldermen and eighteen councillors. Its limits are coextensive with those of the parliamentary borough, which returns two members. Population, 25,325. The number of registered electors in 1869 was 3233.

Eltham, formerly a market town, 7 miles E.S.E. from London Bridge, is a small place of 3009 inhabitants, which deserves notice on account of its remains of a royal palace, built at a very early period, in which Henry III. held Christmas in 1270. Succeeding kings frequently resided in it till the time of Henry VII., when Greenwich Palace was built, and that of Eltham was suffered to fall into decay. The hall, now occupied as a barn, is 100 feet long

by 56 feet wide, with a carved timber roof, and windows which have been very elegant, but are now mostly bricked up. The area of the palace is surrounded by a wall, and the ditch, which is now dry and planted with shrubs, is crossed by an ancient bridge.

Erith is the name of a parish on the right bank of the Thames, covering an extent of 4585 acres, and having 4143 inhabitants. The North Kent Railway has a station here, and in the neighbourhood are extensive powder mills, which were the scene of a terrible explosion in 1864, the report being distinctly heard in, and causing considerable alarm throughout London, about 15 miles distant. There are some extensive lime and sand pits here, from whence ballast is shipped; and the brick-fields in the vicinity are amongst the largest in the kingdom. It has a fine old church of considerable historic interest, and of late years numerous villas have sprung up in its pleasant environs.

Faversham, a market town, municipal borough, and port, is situated on a stream which runs into the East Swale, just to the left of the road to Dover, 47 miles E.S.E. from London Bridge. It was a place of some note before the time of King Stephen, who built and endowed here an abbey for Cluniac monks, in which himself, his queen Matilda, and his eldest son, Eustace of Boulogne, were buried. The town consists principally of four streets forming an irregular cross, and having the guild-hall and market-place in the centre. The church is a large cruciform structure of flint. The town contains also four dissenting chapels, a theatre, assembly-rooms, union workhouse, and gaol. There is a station of the London, Chatham, and Dover Railway at Faversham. Near the town are the extensive gunpowder works of Messrs. Hall & Co. There is also a valuable oyster fishery here. The number of vessels which entered the port in 1867, nearly all coastwise, was 1642 (124,461 tons, and there cleared thence 857 vessels (38,048 tons). The customs revenue in 1868 amounted to 1057*l*. The council of the borough of Faversham, under the Municipal Reform Act, consists of four aldermen and twelve councillors. The creek or arm of the Swale on which the town stands, is navigable for vessels of more than 200 tons. The parish of Faversham is in the Cinque Port liberty of Dover. Population of the parish, 6383.

Folkestone, a bathing-place, seaport, parliamentary and municipal borough, is situated on the shore of the English Channel, opposite Boulogne, partly in a hollow between two cliffs, and partly on the west cliff. Those on one side of the town are chalk, and on the other sandstone. During the last twenty years Folkestone has been much improved, and become a fashionable resort. Spacious streets and noble terraces have been erected in the place of narrow, steep, and winding lanes. The harbour is not capable of affording anchorage to many vessels, admitting only ships of from 10 to 12 feet draught at high-water, but was considerably improved by the South-Eastern Railway Company, when they extended their line to Dover; steam-packets daily ply between Folkestone and Boulogne, and considerable quantities of wine and other French produce are imported. The number of vessels which entered the port in 1867 was 1178 (188,679 tons), and the clearances

906 (154,004 tons). The customs duty received at the port in 1868 was 14,428*l*. The council, under the Municipal Reform Act, consists of four aldermen and twelve councillors. The town forms part of the parliamentary borough of Hythe. Population of the parish of Folkestone, 9674. The village of Sandgate, which is partly in Folkestone parish, is resorted to as a bathing-place, and has a ship-building trade. There is a castle at Sandgate, built by Henry VIII.

Gravesend, a market town, municipal and parliamentary borough, the boarding station for the officers of the London customs, is situated on the south bank of the Thames, 20 miles from London. It has a free school, alms-houses, a battery on its eastern side, a custom-house, numerous baths, libraries, &c. Steamboats run to London in two hours, and one of the earliest passenger steamers (the *Kent*) plied from hence to the metropolis in 1829. But owing to the competition of railways on either side of the Thames, steamers ply only during the summer season. There is a station on the North Kent Railway which, 4 miles beyond, passes through a remarkable tunnel upwards of 2 miles in length, and connects the town with Strood and Rochester. There is a steam ferry across the Thames to the Tilbury station of the London and Southend Railway. Gravesend is a noted resort for holiday-makers from London, who flock here, and to Rosherville and Springhead, which are both in the neighbourhood. The municipal borough is governed by six aldermen and eighteen councillors. Population, including the parish of Milton, 18,782. The town was created a parliamentary borough by the Reform Act of 1867, and returns one member. The number of voters in 1869 was 2639. *Milton*, which adjoins it, has some good houses, and a fine parish church of great antiquity. Cobham Hall, about 4 miles S.E., the residence of the earl of Darnley, is a noble Tudor mansion in a fine park, with a celebrated collection of pictures.

Greenwich, a market town and parliamentary borough, is situated on the south bank of the Thames, 4 miles E.S.E. from London. Greenwich park, which comprises nearly 200 acres, is diversified with lawns, and well planted with elms and chestnut trees. The park, which was laid out from the designs of the celebrated John Evelyn, spreads between the hospital and Blackheath. It was first inclosed by Duke Humphrey of Gloucester, protector in the reign of Henry VI., and still has numerous herds of deer, and some fine old trees. Upon one of its eminences, 160 feet above the river, is situated the Royal Observatory, the residence of the astronomer-royal, commonly called Flamsteed House, and it is from the meridian of this observatory that the longitudes are computed in all British maps. The south gate of the park opens upon Blackheath, where Wat Tyler and Jack Cade both encamped, and which has been the scene of other memorable assemblages. Greenwich communicates with the metropolis by the South-Eastern and Charing Cross Railway. The chief object of interest is the hospital for aged, wounded, or disabled seamen. [GREENWICH HOSPITAL.] In the parish church of St. Alphege lie the remains of General Wolfe and the celebrated Lavinia Fenton, duchess of Bolton. Among the other public edifices of Greenwich are the Trinity

Hospital, founded by the earl of Northampton in 1613, for twenty pensioners (revenue, 2525*l.*); a union workhouse, market-house, and theatre. Greenwich was a royal residence from the year 1300 to the reign of William and Mary. Henry VIII. was born and baptized here, and here he married Anne of Cleves. It was also the birthplace of Queen Mary and Elizabeth, and Edward VI. died in its old palace. Population of the parish 40,002. The parliamentary borough, which returns two members, includes Deptford and Woolwich, and contains a population of 139,436. The number of voters on the register in the year 1869 was 14,579.

Herne Bay, on the north coast of Kent, about 10 miles W. from Margate, has of late years been much resorted to as a watering-place. It has a pier 3000 feet in length, which is now in such a dilapidated condition as to be unsafe even for foot passengers. There is a station of the London, Chatham, and Dover Railway here. The town is situate in the parish of Herne, which is three miles nearer Canterbury inland, and has 3147 inhabitants. The population of Herne Bay itself is only 1503. Extensive oyster farming was commenced here in 1865.

Hythe, a municipal borough, parliamentary borough, and one of the Cinque Ports, 15 miles S. from Canterbury, is situated at the foot of a steep hill or cliff, about half a mile from the shore, and consists chiefly of one long street, parallel to the sea, with some smaller ones branching from it. There is a rather extensive avenue of trees from the principal street to the waterside. The town-hall and market-place are in the centre of the town. The church, on the slope of the hill above the town, is very ancient. The South-Eastern Railway has a station at Westerhanger, near Hythe. The now well-known school of musketry—whose rules are observed by all the volunteers in Great Britain—was established here in 1855; and on the beach, which is higher than the town, are posted several strong martello towers. Hythe has also a county hall, borough gaol, theatre, and hospital. The corporation of Hythe, under the Municipal Reform Act, consists of four aldermen and twelve councillors. Hythe formerly returned two members to Parliament, but since 1832 it sends only one. The parliamentary borough includes the municipal borough, the liberty of the town of Folkestone, and the parishes of West Hythe, Saltwood, Cheriton, and Folkestone, and part of that of Newington. These limits include the watering-place of Sandgate. Population of the municipal borough, 3001; of the parliamentary borough, 21,367, including Folkestone: electors (1869), 2209.

Lee is now a well-populated suburban parish, inhabited chiefly by wealthy city merchants, on the south side of Blackheath, 6 miles E.S.E. of London. The parish comprises 1273 acres, and has a population of 6162.

Lewisham is 6 miles S.E. of London, of which city it may almost be said to be a suburb. The parish includes the chapelry of Sydenham, and the total population is 22,808, a large number of whom are engaged in business in London, travelling to and fro every day.

Lydd, a market town on the English Channel, was formerly a member of the Cinque Port of New Romney, from which it is distant about 3 miles.

Accumulations of shingle have destroyed the port, and it is now a poor village, one mile inland, with a population of only 1667.

Maidstone, a municipal borough, parliamentary borough, and the assize town of the county, is situated on a declivity on the east bank of the Medway, 8 miles from Rochester, and 36 miles from London, at the meeting of two branches of the South-Eastern Railway. The town is in a pleasant position in the central vale of Kent, has a fine parish church, known as the 'Pilgrim's Chapel,' and many almshouses and charities. There are also a former palace of the archbishops of Canterbury, a town and county hall, gaol, and lunatic asylum, barracks, theatre, library, philosophical society, an excellent museum, &c. The grain market is the largest in Kent. In the vicinity are paper and oil mills, and some of the most productive hop grounds and orchards in England; also valuable quarries of stone, which is exported by the Medway, navigable here for vessels of sixty tons. Trade is thriving, and the town increasing. Maidstone is the chief place of election for Mid Kent; and the borough sends two members to the House of Commons. In 1869 the number of voters on the register was 3250. There was an important city of the early Britons in the neighbourhood of this town. In the reign of Henry VIII. the first English houses were raised here. In 1648 Maidstone was twice stormed by the parliamentary forces. The municipal borough is divided into four wards, and is governed by six aldermen and eighteen councillors: population, 23,016. The parliamentary borough has a population of 23,058.

Margate, a seaport town and municipal borough in the Isle of Thanet, on the north coast of the county, about 3 miles from the North Foreland, and 65 miles E. by S. from London. Margate has been of late years a favourite sea-bathing place. A curved stone pier with a lighthouse was erected at the beginning of the present century, which has very greatly improved the harbour, previously much exposed to winds from the N.E., and there is a noble jetty, at which the steamers land and embark passengers. The modern streets and public structures, including a Gothic and other churches, an esplanade, squares, &c., are well built. Population of the parish, 10,019. Margate is connected with London, Canterbury (15½ miles distant), and Ramsgate (3 miles), by branches of the South-Eastern and Kent Coast railways. It lies in the hollow, and on the declivities of two chalk hills; has a royal bathing infirmary, town-hall, and market-house, assembly rooms, theatre, public library, baths, and several fine hotels. The harbour has 8 to 13 feet at high water, but is dry at low water. Margate was recently made a municipal borough. The population within the municipal limits is 8874; but in the season it often contains from 50,000 to 100,000 persons, who visit it for its excellent sea-bathing.

Milton is a market town situated on a creek of the Swale, 39½ miles from London. The town is on the side of a hill sloping down to the creek, and is ill-built. The business of the place arises from its celebrated oyster fishery, and from its being the port of communication with London for the surrounding agricultural district. In the centre of the town is the ancient court-house for holding the manor courts,

with the town gaol beneath. Much corn is shipped here. The church is chiefly in the decorated English style, and is large and handsome. Population, 2731.

Penshurst, on the South-Eastern Railway, 32 miles from London, is a pleasant village, with an interesting church, and much visited as the ancestral residence of the Sidney family. Sir Philip Sidney was born at Penshurst Place, now the seat of Lord de Lisle and Dudley.

Plumstead is a large manufacturing parish, 10 miles E. from London, with which it is connected by railway, and includes a great part of the royal arsenal. Population, 24,502. It forms part of the borough of Greenwich.

Queenborough, in the Isle of Sheppey, 45½ miles from London, belonged to the Saxon kings, who had a castle here, on the site of which Edward III. commenced a new and more extensive fortress. Edward made the town a free borough, and gave it the name of Queenborough, in honour of his consort Philippa. This castle was demolished in the time of the Commonwealth. Queenborough is now a poor place, and the greater part of the inhabitants are dependent on the oyster, shrimp, and lobster fishery. Queenborough was disfranchised by the Reform Act of 1832, before which it returned two members to Parliament. Population of the parish, 973.

Ramsgate, a market town, port, and favourite sea-bathing place, is situated in the Isle of Thanet, about 4 miles S. from the North Foreland. An excellent harbour has been constructed, which has contributed greatly to the prosperity of the town. It is the largest artificial haven in England, being formed by two piers, constructed of Purbeck stone and granite, which project from 1500 to 2000 feet into the sea, and inclose an inner basin. This harbour is bordered by wet and dry docks; vessels of 300 tons burthen enter it at ordinary tides; a lighthouse stands at its entrance, and it is guarded by batteries. The port has a little coasting trade and fisheries; eggs, fruit, and other provisions from France and Belgium are its chief imports. The entries in 1867 were 296 (27,364 tons), the clearances 30 (2707 tons). The customs revenue in 1868 amounted to 3616*l*. The old part of the town is in a hollow between two chalk ridges, on which the modern portion is built. There are terraces, crescents, bathing-rooms, assembly-rooms, a handsome modern Gothic church, several places of worship for dissenters, custom-house, bank, barracks, and market-house. Ramsgate is 15 miles E.N.E. of Canterbury, with which, and with London, Margate, &c., it is connected by two railways. Steamboats also ply to and from London, except during winter. It is a member of the Cinque Port of Sandwich. Population of the parish, 11,865.

Rochester. [ROCHESTER.]

Romney is called *New Romney*, to distinguish it from *Old Romney*, which is a little farther inland, and had been deserted by the sea before the time of Edward the Confessor, when the harbour of New Romney was formed. New Romney is situated on the east coast, about 4 miles N. from Dungeness. It is one of the Cinque Ports. The town stands in Romney Marsh, an exceedingly fertile, level tract, which is used as pasture land, chiefly for sheep, and which is defended from the encroachment of the sea by a high and broad embankment called Dymchurch Wall,

which extends northwards about 4 miles to the village of Dymchurch. This embankment is under the management of a corporation. The *Marsh* is 24,000 acres in extent. The town consists chiefly of one wide well-paved street, with a market-house and a hall. There is a weekly market. The church is a very ancient and handsome building. Romney is 22 miles S.S.W. of Canterbury, and is the head of a poor-law union, a prescriptive but decayed municipal borough, and a polling-place for the eastern division of the county. Its harbour was destroyed by an irruption of the sea. Population of the Cinque Port and parish, 1062.

Old Romney, 2 miles west of the new town, now has only 151 inhabitants.

Sandwich, a municipal and parliamentary borough, and Cinque Port, is situated 12 miles E. from Canterbury, near the east coast, and on the south side of the Stour, at its entrance into Pegwell Bay. It is a very ancient town, and had once a fine harbour, but the sand had begun to fill it up before the reign of Elizabeth, and in the reign of Edward VI. it was almost entirely destroyed. Only vessels of small draught can now get up to Sandwich. The streets are irregular, and the houses antique. There are two ancient churches, both of which have been injured by tasteless modern alterations. Sandwich is 4 miles N. of Deal, with a station on the South-Eastern Railway. It was formerly of importance as the seaport of London, and is nearly inclosed by the remains of fortifications; has a third parish church, a guild-hall, gaol, two hospitals, and several dissenting chapels. At spring tides the Stour at this point is about 11 feet in depth, and 150 feet across. At present the trade of the port is very little, the chief exports being agricultural produce, wool, malt, bark, and ashes. Coal is the chief article imported. Near Sandwich is Richborough, the ancient *Rutupium*, on whose decline this town arose in the sixth century. The municipal borough is governed by four aldermen and twelve councillors. Population of the town and port, 2944. Population of the parliamentary borough, which includes Deal and Walmer, and returns two members, 13,750. The number of registered electors in 1869 was 1849.

Sevenoaks, a market town, is pleasantly situated on the northern slope of the North Downs, near the upper course of the Darent, 24 miles S.E. from London. The town is well built, and contains many good houses. The church is of perpendicular architecture, spacious and elegant; and there is a well-endowed grammar-school. The surrounding district is very fertile. In the neighbourhood is Knole House, the seat of Earl Delawarr, a splendid manorial mansion in the Tudor style. It contains a good picture gallery, and some choice relics of antiquity. The park is of great extent, and includes some beautiful scenery. Knole was anciently the residence of the Sackville family. Population of the parish, 4695.

Sheerness, a seaport town and naval arsenal, is situated on the north-western part of the Isle of Sheppey, on the eastern side of the Medway, at its junction with the Thames, 51½ miles E. from London by the London, Chatham, and Dover Railway. The town consists of four parts; Blue-town, which is inclosed by an outer line of fortifications; Mile-town, which is an outer uninclined suburb; Marine-town;

and Banks-town. The fortress occupies the extreme point of the island, and the principal batteries front the Thames. The dockyard is surrounded by a brick wall, and is sufficiently capacious to receive ships of war of the largest size. It occupies nearly 60 acres; contains a wet dock of $3\frac{1}{2}$ acres, in which ships are fitted, several dry docks, large storehouses, a mast-house, rigging-house, sail-loft, &c., with residences for the port-admiral, commissioner, and other officers. Outside of the yard is Garrison Point, with telegraph and coast-guard stations, and large barracks. Opposite the river and sea is a long wharf, and a break-water has been constructed for the protection of the harbour. The town, latterly much improved, has a pier, bathing establishment, a district church belonging to the Establishment, dissenting chapels, Jews' synagogue, and numerous schools. Corn, seeds, and oysters are exported to London; but the trade lies chiefly in the supply of the government establishments. There is constant communication by steamers and railway with London and Chatham. Sheerness was attacked by the Dutch under De Ruyter in 1667. The mutiny of the *Nore* broke out in this port in 1798. Population of the parish of Minster-in-Sheppey, which includes the village of Minster, as well as Sheerness and its suburbs, 15,964. Sheerness itself contains 12,015 inhabitants within the limits of the ecclesiastical district and the local board of health.

Sittingbourne is 40 miles E. by S. from London, and 10 from Rochester. The town, which is increasing, has both an ancient and modern church, some handsome dissenting chapels, a corn-exchange, and a station on the London, Chatham, and Dover Railway. There is also communication with London by barges. Population of the parish, 4301.

Staplehurst is a small place, with a station on the South-Eastern Railway, $4\frac{1}{2}$ miles N.N.E. of Cranbrook. Population, 1695. A terrible railway accident occurred here in the summer of 1865, by which several persons lost their lives.

Strood is a continuation, on the other side of the Medway, of the city of ROCHESTER, to which it is joined by a bridge, and within the limits of which this town is comprised. Population, 4057. Here are stations of the South-Eastern, and London, Chatham, and Dover railways, the latter crossing the river by a tubular iron bridge.

Sydenham is a chapelry in the parish of Lewisham, with a station on the London and Croydon Railway, 8 miles S.S.E. of London Bridge, having a population of 10,595. On the 10th of June, 1854, the Crystal Palace was opened here by the queen. [CRYSTAL PALACE.] It covers nearly three-quarters of a mile of ground, and the cost of its erection was about 1,000,000*l*. Numerous elegant villas cover the surrounding country.

Tenterden, a market town and municipal borough, is 55 miles S.E. from London. It consists chiefly of one main street along the Romney road, and contains some good houses. The church is of perpendicular architecture, with a lofty tower at the west end. The municipal borough is governed by four aldermen and twelve councillors. Population of the parish, 3656, chiefly agricultural. The town stands on an eminence, environed by hop-grounds, and near it are the Romney Marshes. The population of the municipal borough is 3762.

Tunbridge, or *Tonbridge*, a market town, is on the north bank of the Medway, 27 miles S.E. from London. The town consists chiefly of one street, broad, partially paved, and being on a declivity is remarkably clean. There are five stone bridges over the Medway, which is here divided into five arms, one of which is called the Tun. Near the principal bridge is a wharf, and the Medway is made navigable to Maidstone by means of locks. The church is a large and handsome fabric, in various styles of architecture. The ruins of the castle and the ruins of a priory partly remain. The South-Eastern Railway passes by Tunbridge, which is one of its principal stations, and there is a branch from Tunbridge to Hastings, through Tunbridge Wells. Population of the town proper, 5919. The parish of Tunbridge comprises 15,235 acres (including part of the town of Tunbridge Wells), with 21,004 inhabitants. Tunbridge is a quiet old town, and has been long noted for a manufacture of toys and turned wares, having also some exports of timber. The principal buildings are a new school in the Gothic style; the grammar-school, which is most liberally endowed, having sixteen exhibitions of 100*l*. each at the universities, twelve minor exhibitions, a scholarship and a fellowship at Oxford, and 700*l*. in salaries to masters; the town-hall, union workhouse, market-house, chapels, &c.

Tunbridge Wells, a market town and a place of fashionable resort, is five miles S. from Tunbridge, on the border of Kent and Sussex, part of it being in each county. The chalybeate spring, to which the town owes its origin, is nearly equal in strength to that of Spa, in Germany. When Henrietta, queen of Charles I., visited the Wells, she and her suite remained under tents. After the Restoration the place rapidly increased. The springs are in the centre of the town, and the pump-room and baths, public parade, ball-rooms, libraries, theatre, and market-house, are in a small valley inclosed by sloping hills—Mounts Ephraim, Pleasant, and Sion. The site of Tunbridge Wells was once supposed to resemble that of Jerusalem, which led to the application of these sacred names. There are also a church and elegant chapel, numerous dissenting places of worship, an infirmary, dispensary, and many schools and literary institutions. The population within the limits of the jurisdiction of the local board—including portions of the three parishes of Tunbridge, Speldhurst, and Frant (in Sussex)—is 13,807.

Walmer is a parish on the east coast, 1 mile S.S.W. of Deal, in which municipal borough it is included. Population, 3275. It is also comprised in the parliamentary borough of Sandwich. The village of Upper Walmer adjoins Deal, and separated from it on the S.E. is Lower Walmer, on rising ground near the shore, containing the church, and resorted to for sea-bathing. Facing the sea, opposite the Downs, is Walmer Castle, the official residence of the Lord Warden of the Cinque Ports.

Westerham is 21 miles S.S.E. from London, near the source of the Darent. It is a market town. Population of the parish, 2196, chiefly agricultural. In the church is a monument to General Wolfe, who was born here, and whose victory at Quebec is commemorated by a pillar in this parish. His remains lie at Greenwich.

Whitstable is about 6 miles E. from Canterbury,

with which city it communicates by a railroad. It is the port of Canterbury, being situate at the entrance of the Swale into the estuary of the Thames, opposite the Isle of Sheppey. Population of the parish, 3675; of the town (including part of the parish of Seasalter), 4183; mostly engaged in the oyster fisheries. Whitstable, formerly only an insignificant fishing place, is rapidly rising into importance. The extensive oyster grounds here are dredged by an incorporated company of working fishermen, whose gross returns are sometimes 40,000*l.* per annum. The town is protected by substantial embankments from landfloods and incursions of the sea. It has two churches, one forming an important landmark. This place was the principal scene of the exploits of the religious impostor Thorn, or Sir William Courtenay, as he loved to style himself, who was shot in 1838; and here was first brought into operation the diving apparatus invented by Charles Deane. It has a large coal trade, and stations on the South-Eastern and London, Chatham, and Dover railways.

Woolwich, an arsenal and naval port, is on the south bank of the Thames, 9 miles E. from London, with which it is connected by railway. The population is chiefly dependent on the government establishments. The town, about a mile in length, is on an elevated site, separated from the Thames by the dockyard; it has an old church, a new church, and several chapels; a Scotch church, dissenting chapels, numerous schools, and a theatre. The dockyard, upwards of a mile long, is the most ancient in the kingdom, and has some fine new docks. Ships were first built here in Henry VII.'s reign. From the comparative shallowness of the water, this yard was chiefly employed for the construction of steamers, but it has not been used as a government establishment since 1869. The arsenal is the largest in Great Britain, covering more than 100 acres, and containing nearly 24,000 pieces of ordnance, besides other warlike materials for the army and navy, a royal laboratory, &c. It is the headquarters of the royal horse and foot artillery, for whom, and other corps, there are extensive barracks, with a frontage of over 400 yards; and on a fine parade ground south of the town are a repository for military models and an observatory. Woolwich is also the seat of a royal and military academy for engineering and artillery. Admission to the royal arsenal can only be obtained by an order from the War office, or from one of the heads of the departments. The number of inhabitants within the limits of the parliamentary borough—which, with Deptford and Greenwich, returns two members to the House of Commons—is 40,975.

History and Antiquities.—The name of this county is supposed to be Celtic, and Dr. Guest identifies it with *Caint*, or the 'open country.' No portion of England played a more important part than Kent in the Roman times; it was the scene of Caesar's first attack; and in most of the subsequent invasions it lay, from its proximity to the Continent, in the track of the invaders. There were Roman stations at Reculver, Richborough, Dover, and Hythe; and roads from Canterbury to these places and to London by the road called Watling Street. Richborough Castle, near Sandwich, is the *Rutupie* of the Romans. The walls form a parallelogram, but that on the eastern side has

disappeared, and probably fallen into the Stour. The area within the walls is five acres. A quarter of a mile from the south-west angle of the castle lie the remains of a Roman circular amphitheatre of about seventy yards' diameter. Many portions of the Brito-Roman Watling Street coincide with the present high road from London to Canterbury.

In the Saxon invasion Kent was the scene of certain interesting events. The brothers Hengist and Horsa landed in Pegwell Bay, probably about 446 or 449, though Kemble and Lappenberg impugn the authenticity of this historical incident. Having received a grant of the Isle of Thanet, then insulated by a channel of some width, they received accessions of strength from their countrymen at home, and were soon involved in hostilities with the Britons. Many irruptions of the Jutes followed, and many battles between them and the Britons. In 752 Kent was subject to Mercia, being the first established kingdom of the Saxon Heptarchy. In 823, after the successes of Egbert, it became a subordinate part of the West Saxon empire, commonly forming the appanage of the eldest son, or heir-apparent, of the king of Wessex; and when the heir succeeded to the paramount sovereignty, he usually resigned the Kentish crown to his heir. During the reign of Ethelwulf in Wessex, and of his sons in Kent, the latter kingdom was repeatedly attacked by the Danes, and down to the time of the Norman Conquest this county was seldom free, for any considerable period, from their hostile incursions.

At the great battle of Hastings the men of Kent formed the vanguard of the Anglo-Saxon army. At the outbreak of the war of the Roses in 1451, Richard, duke of York, encamped near Dartford, where he fortified himself. Henry VI. made Blackheath his headquarters. In the civil war of Charles I. and the Parliament, a severe battle was fought at Maidstone in 1648, in which the Parliamentarians, under Fairfax, obtained a complete victory. In 1667 a detachment from the Dutch fleet under De Ruyter sailed up the Medway, and in defiance of the forts on its banks, succeeded in burning many vessels and a considerable quantity of stores.

Of ancient castellated edifices, the most remarkable are the castles of Rochester, Dover, Leeds, Chilham, Tunbridge, and Westerhanger, to which may be added the manorial mansions of Penshurst, Knole, Hever, Allington, and Cobham. Leeds Castle, partly modernized, is surrounded by a broad moat: the entrance is by a stone bridge of two pointed arches, and through a deep gateway in good preservation. Another gateway, which defended the entrance of the bridge, is in ruins. Hever Castle, the seat of the Boleyns, is surrounded by a moat: the entrance gateway is flanked by round towers; the inner buildings form a quadrangle inclosing a court. Chilham Castle was a Norman structure, of which the keep is the only part now remaining. Of Westerhanger the principal relics are the outer walls, with the towers of the N. and E. sides. Penshurst Place is one of those castellated dwellings that immediately succeeded the baronial castles of a more troubled period. The principal buildings form a quadrangle inclosing a spacious court, and comprehending a hall, chapel, and other apartments. Knole is another extensive and magnificent mansion: the

principal buildings form a capacious quadrangle, and are in the castellated style. The greater part is of the fifteenth century, but some portions are yet older.

Of monastic remains, the principal are St. Augustine's Abbey, at Canterbury, Aylesford Priory, St. Radigund's Abbey, near Dover, the abbey of Faversham and Malling, the priories of Tunbridge and Folkestone, and Boxley Abbey, near Maidstone. Besides the cathedrals at Canterbury and Rochester, the most interesting ancient church, perhaps, is that of Barfreston, between Canterbury and Dover.

KENT, HOLY MAID OF. [BARTON, ELIZABETH.]

KENT, WILLIAM, was born in Yorkshire, in 1684, and was apprenticed to a coach-painter. In 1716, while in Italy, he became acquainted with the earl of Burlington, who became his patron, and under whose roof he resided till his death, April 12, 1748. Kent soon discovered greater capacity for architecture than for painting and sculpture; and if it be true that the designs for Holkham, the seat of the earl of Leicester, in Norfolk, emanated principally if not entirely from him, that single edifice alone proves him to have possessed superior talent. In landscape gardening he attained great excellence, and may justly be considered as the father of the English style.

KENTISH FIRE, a term applied to the cheers and vehement applause with which the rabble greeted the no-popery orators at the public meetings held in Kent to prevent the passing of the Roman Catholic Relief Bill, 1828-29.

KENTISH RAG (Geology), a provincial term for one of the beds of the lower greensand. It occurs at Hythe and near Maidstone in Kent, is of a gray appearance, and consists of chert or arenaceous limestone, sometimes about 70 feet thick. The stone is highly fossiliferous, and is much used as a building material where durability is required.

KENTUCKY, one of the United States of North America, is situated between $36^{\circ} 20'$ and 39° N. lat., and between 82° and $89^{\circ} 20'$ W. long. It is bounded N. by Ohio, Indiana, and Illinois, from which it is separated by the river Ohio; E. by Virginia; S. by Tennessee; and W. by the Mississippi, which separates it from Missouri. Its greatest length is about 400 miles, and its greatest breadth about 170 miles. The area is 37,680 square miles. The population in 1860 was 1,155,684, of whom 10,684 were free coloured, and 225,483 slaves; it is now estimated at 1,320,000, all free.

Surface.—The south-eastern and eastern parts of Kentucky are covered with mountain ridges and high hills. None of the summits of these mountains appear to attain the height of 3000 feet above the sea. The highest range is that of the Cumberland mountains, in the S.E. To the west of the hilly region lies an upland region, which extends to about 86° W. long. The surface is undulating, but it is intersected by numerous river beds, which are from 100 to 300 feet below the surface of the plain. The soil is of the first quality. It rests extensively on a formation of limestone, apertures in which greatly diminish the rivers in dry seasons. The most western portion of the state is divided between the Barrens and a country which is partially hilly. The Barrens are in the S.W., between Green River and Cumberland River.

In their natural state they are generally destitute of trees, and resemble the prairies or savannahs which occur north of the Ohio. Though this tract does not deserve the name which it bears, it is of inferior fertility when compared with the upland region.

Hydrography.—Along the northern boundary runs the Ohio, which receives all the larger rivers that drain Kentucky. The most eastern is the Sandy River, which separates this state from a part of Virginia. It flows in a northern direction, and has a course of about 250 miles. The branches of the river Kentucky rise in the eastern part of the state, and form by their union a considerable stream, which first flows N.W., then W., and at last nearly due N. Its course is about 280 miles, and though very rapid, has been made navigable for steamers throughout 260 miles. Green River rises in the western districts of the upland region, and flows W., N.W., and N. to the Ohio. Its course is 280 miles. Cumberland River rises in the eastern part of the state, and flows W. and S. into Tennessee, where it makes a large bend, then re-enters Kentucky, and flows N.W. to the Ohio. It is above 500 miles long. Licking River and Salt River are also of considerable size. The river Tennessee flows only about 70 miles through Kentucky.

Climate, Products, &c.—The mean annual temperature of Kentucky seems to be about 55° , or 5° higher than that of London, but the differences in the extremes of heat and cold are much greater. The climate is considered healthy, except near the Mississippi; the winters are generally mild and humid. Wheat, tobacco, and hemp are the staple products; but Indian corn, rye, oats, barley, buckwheat, flax, and potatoes are also cultivated. Horses, cattle, bacon, beef, pork, and dairy produce are largely exported. The breed of horses is greatly valued throughout the Union. The forests support millions of swine, and there is abundant pasturage for almost endless herds of cattle. Iron, lead, marble, coal, salt, and lime are obtained. The greater part of the products of the state pass down the Ohio and Mississippi to New Orleans.

At the last census there were in this state 3450 manufacturing establishments, employing 21,258 persons, principally saw and flour mills, tanneries, distilleries, breweries; and tobacco, cordage, leather, woollen, and clothing factories. There are twenty colleges, 4507 public schools, 223 academies, 196 libraries, and 2179 churches and chapels.

There are 590 miles of railway in the state, and 766 miles of water navigation. The rapids of the Ohio are avoided by a canal.

Divisions, Chief Towns, &c.—Kentucky is divided into 110 counties. Frankfort, the capital, is situated on the banks of the Kentucky, 60 miles above its junction with the Ohio, in $38^{\circ} 14'$ N. lat., $84^{\circ} 40'$ W. long. Steamboats of 300 tons burthen come up to the town. The State-house is a handsome edifice of marble quarried in the vicinity, with a portico supported by six Ionic columns. Population, 8702. Lexington is situated on a branch of the Elkhorn River, 24 miles E.S.E. from Frankfort. It is the oldest town in the state, and was formerly the capital. It is well built, and contains several places of public worship, a state lunatic asylum, the halls of the Transylvania University, and 9521 inhabitants.

Louisville is the largest town in the state, and is situated on the south bank of the Ohio, in $38^{\circ} 8' N.$ lat., $85^{\circ} 26' W.$ long., about 50 miles *W.* by *N.* from Frankfort. It has increased with extraordinary rapidity. In 1800 the population was 600; in 1860 it was 68,033. The Ohio is more than a mile wide opposite the town, and there is a very large traffic on it by steamboats and river craft. *Maysville*, on the south bank of the Ohio, 81 miles *N.E.* from Frankfort, has a population of 8000. It is the *entrepôt* for the north-west section of the state, and a great hemp mart. The other towns are *Covington*, *Newport*, *Danville*, and *Paducah*.

History.—The first Europeans arrived here in 1767, and the first settlement was formed in 1775. It was originally a part of Virginia, but the population having increased rapidly, Virginia consented to a separation. The first constitution was formed in 1790, and its present constitution in 1799. The legislative body consists of thirty-eight senators, who, with the governor of the state, are elected for four years, and one hundred representatives, who are elected for one year. It sends two senators and ten representatives to Congress.

In the American civil war, 1861–65, Kentucky was the scene of many conflicts, and its inhabitants were divided as to which cause they espoused. The name of the state is of Indian origin, and signifies ‘the dark and bloody ground,’ in consequence of the sanguinary contests which took place on its soil in the displacement of the old and warlike Indian tribes.

KENYON, LLOYD, LORD, the second son of Lloyd Kenyon, was born at Greddington in Flintshire in 1733. His education was, owing to the straitened means of his father, very defective. At the age of fourteen he was articled to Mr. Tomlinson, an attorney at Nantwich in Cheshire, with whom he remained for seven years, during which time his diligence and shrewdness procured him his master’s favour. In 1754 he took chambers in the Temple, London, and became a member of Lincoln’s Inn. While a student, he devoted himself with great earnestness to the law. Mr. Kenyon was called to the bar in Hilary Term, 1761, but many years elapsed before he obtained business. His legal attainments appear to have been not only considerable but exact, and he acquired by degrees the reputation of being a sound lawyer. In 1773 he married Mary, third daughter of George Kenyon, of Peele in Lancashire. He now began to rise into notice. In 1779 he was retained as one of the counsel for Lord Pigot in the state prosecution of Shelton and others for depriving him of his government; and afterwards in the same year as leading counsel for Lord George Gordon. In April, 1782, on the accession of the Fox and Rockingham administration, he was appointed attorney-general, but went out with the Shelburne administration in the spring of the year following. In December he was reappointed attorney-general. To the character of an orator he had no pretension, being a man of little imagination, and expressing himself not only without elegance, but occasionally with vulgarity. He was no scholar, and yet he would insert Latin words and phrases without point or taste in his discourse.

In 1784 he was raised to the office of master of the rolls, and created a baronet; and in May, 1788,

he was gazetted Lord Kenyon, Baron Greddington, and succeeded Lord Mansfield as chief-justice of the King’s Bench. His appointment to this important situation was at the time unpopular with the profession generally. The opinion of his brother judges he received not only with neglect, but almost with contempt; and to the barristers he was equally ungracious.

Lord Kenyon struck sternly at those offenders who are the peculiar objects of popular dislike. But while doing so he frequently gave too easy credit to accusation, and allowed himself to punish often with a severity not sufficiently tempered. The vices of the wealthy met with no favour from him. He exerted himself to the utmost to put an end to duelling, and declared that whoever was convicted of having murdered his fellow-creature in a duel should suffer the course of the law; and he on more than one occasion directed the jury to that conclusion, but without success. Flagitious libels against individuals he punished with merited severity. But of all writings, it was against those partaking of the character of political libels that he directed, with the most unflinching perseverance, all the terrors of the law. He died, 2nd April, 1802, after having accumulated a fortune of 300,000*l.* Lord Kenyon was temperate, frugal even to parsimony, and an early riser. For his happiness he looked to his home. He entirely disregarded outward appearance: his dress was shabby, his equipage mean, and he wholly neglected the exercise of hospitality.

KEPLER, JOHN, a celebrated astronomer, was born at Weil, a small town of Württemberg, on the 21st December, 1571. His parents, Henry Kepler and Catherine Guldenmann, though of noble descent were in indigent circumstances. Their son being a seven months’ child was very sickly during his early life; and when he was only five years of age he was placed under the charge of his grandfather at Leonberg, near Stuttgart, in consequence of his father and mother having joined the army in the Netherlands. In 1586 he was admitted into the school at the monastery of Maulbronn, where he was educated at the expense of the duke of Württemberg. At the University of Tübingen he took his degree of master in 1591, holding the second place in the examination. It does not appear how Kepler was occupied, and how he supported himself for two or three years after he graduated at Tübingen. While he was attending the lectures of the celebrated Moestlin, who had distinguished himself by an oration in favour of Copernicus, Kepler became a convert to the opinions of his master, and wrote an essay on the primary motion (the apparent daily motion of the heavenly bodies), in order to prove that it was produced by the diurnal rotation of the earth upon its axis. He succeeded George Stadt as professor of astronomy at Grätz in 1593 or 1594. In this situation he continued to lecture on astronomy, of which he had very little knowledge; but in 1595, ‘when he had some intermission of his lectures, he brooded with the whole energy of his mind on the subject, inquiring pertinaciously why the number, the size, and the motion of the planetary orbits were not other than they are.’ His ‘*Prodromus Dissertationum Cosmographicorum*’ appeared at Tübingen in 1596, and was commended by Galileo and Tycho; but the latter

judiciously advised him 'to obtain a solid foundation for his views from actual observations, and then by ascending from these to strive to reach the causes of things.' In 1592 Kepler paid his addresses to Barbara Muller von Muleckh, a young lady of nineteen, but the marriage was not agreeable to her parents; and when it was again proposed in 1596, they refused their consent till Kepler produced a proof of his nobility. In 1597 the marriage took place, the lady having been a widow for the second time. Kepler's salary being very small, and his wife's fortune less than was expected, he was involved in pecuniary difficulties and disputes with her relations. In 1600 he paid a visit to Tycho Brahe, then living at Benach, near Prague, an exile from his country; and during his residence there he had agreed to become assistant to Tycho for two years, with a salary of one hundred florins, provided he could retain the salary of his chair at Grätz. In 1601 Kepler was introduced by Tycho to the Emperor Rodolph, who conferred upon him the title of imperial mathematician on the condition of his assisting Tycho; and the two astronomers agreed to combine their talents in the computation of new astronomical tables, to be called the Rudolphine Tables, from the generosity of the emperor who had promised to defray the expense of them. The death of Tycho in October, 1601, put a stop to this important arrangement; but Kepler was appointed principal mathematician to the emperor, with an ample salary to be paid in March, 1601. This promise, however, was not fulfilled; and from the non-payment of his salary he was obliged to postpone the Rudolphine Tables, to devote his time to the completion of other works, and even to cast nativities; though it appears from other parts of his writings that he held astrology in contempt. In 1602 he published at Prague his work, '*De Fundamentis Astrologiæ*;' and in 1604, at Frankfort, his '*Paralipomena ad Vitellionem*'—a work containing much new and interesting information on dioptrics and vision. In 1605 he published his '*Epistola de Solis Deliquio*,' and in 1606 his treatise '*De Stella nova*,' the new star which appeared in 1604 in Serpentarius, and which, like that of 1572, rivalled even Venus in lustre. In 1609 Kepler published at Prague his greatest work, entitled '*Astronomia Nova, seu physica cælestis tradita commentariis de motibus stellæ Martis*.' In 1601, when residing with Tycho, he had begun the researches contained in this volume. He had failed in every attempt to represent the observations on Mars by a uniform motion in a circular orbit, and by the aid of the cycles and epicycles, as employed by Copernicus in explaining the planetary inequalities; and having, after many abortive speculations, conjectured that the orbit of the planet might be of an oval form, he was led to the conclusion that Mars moved in an elliptical orbit, with the sun placed in one of its foci. His knowledge of the conic sections enabled him to determine the major and minor axis of the ellipse; and by comparing the times in which the planet describes any portion of its orbit with the time of a whole revolution, or the time of describing any other portion of it, he found that these numbers were always to one another as the areas contained by lines drawn from the sun's centre, or focus of the ellipse, to the extremities of the respective portions or arches of the orbit; or,

more precisely, that the radius vector or line joining the sun's centre and Mars describes equal areas in equal times. Kepler's third law, that the squares of the periodic times are proportional to the cubes of the mean distances of the planets from the sun, was not discovered till nine years after he had discovered the other two laws. It was published in 1619 at Linz, in his '*Harmonia Mundi*,' which was dedicated to James I. of England. In 1611 he published at Frankfort his '*Dioptrica*,' with an appendix on the use of optics in philosophy. In this excellent work, which was reprinted in London in 1653, he explained the principle of the telescope, and described the astronomical telescope with two convex lenses, which was his own invention, and which was greatly superior to that of Galileo, from its admitting in front of the eye-glass micrometer wires for measuring distances in the heavens. He proved that spherical surfaces cannot converge rays to a single focus; and he conjectured what Descartes afterwards proved, that this property might be possessed by surfaces having the figures of some of the conic sections. Kepler's wife was seized in 1610 with fever, epilepsy, and phrenitis, and three of his children were attacked with the small-pox. His favourite son died of the complaint; and while Kepler was in the midst of poverty and domestic affliction, Prague was oppressed with Austrian troops, who had introduced the plague into the city. Disappointed in obtaining the arrears of his salary, Kepler went to Linz in the hope of being appointed to the mathematical chair. The Emperor Mathias permitted Kepler to accept the professorship at Linz, and continued him in the office of imperial mathematician. Soon after this his wife died. He had now a son and a daughter, both of tender age, who required a mother's care; and he married a girl of humble station, whose person, manners, and excellent education he considered better than a good dowry. The marriage seems to have taken place in 1614, as he mentions it in his book entitled '*Nova Stereometria*,' which appeared at Linz in 1615. In the year 1617 Kepler published at Linz his '*Ephemerides*' for 1617–20, the Ephemeris for 1620 having been dedicated to Baron Napier of Merchiston; and in 1624 he published his '*Chilias Logarithmorum*,' an imperfect table of logarithms. In 1618 Kepler published at Linz the three first books of his '*Epitome Astronomiæ Copernicanæ*.' The fourth book was published at the same place in 1622; and in the same year the fifth, sixth, and seventh books appeared at Frankfort. This work, which contains a summary of his astronomical discoveries, was prohibited both at Rome and Florence, to the great annoyance of its author.

When Ferdinand succeeded to the imperial throne, he ordered the arrears of Kepler's salary to be paid, and supplied the means of publishing the Rudolphine Tables, which appeared at Ulm in one volume folio in 1628. Honours and appointments were now showered down upon the astronomer. The grand-duke of Tuscany sent him a gold chain in approbation of his services to science; and the duke of Friedland induced him, by the munificence of his offers, to settle at Sagan in Silesia in 1629. By the duke's influence he was appointed to a professorship in the University of Rostock. During his residence

at this place he published his last work, entitled 'Terrentii epistolum cum commentationculâ,' which appeared at Sagan in 1630.

The arrears of his salary had again been allowed to accumulate, and now amounted to eight thousand crowns. In the hope of obtaining it he went to Ratisbon; but having failed in his mission, the fatigue of his journey, combined with mental anxiety, threw him into a fever, accompanied with an imposthume in his brain, which carried him off on the 5th of November, 1630, in the sixtieth year of his age, leaving behind him a wife, three daughters, and four sons, all of whom died young excepting Louis, who died a physician at Königsberg in 1663. The remains of Kepler were interred in St. Peter's churchyard at Ratisbon. An admirable life of him will be found in the 'Library of Useful Knowledge,' by the late Mr. Drinkwater Bethune, and one of a more popular character in Sir David Brewster's 'Martyrs of Science.'

KEPLER'S LAWS. We have referred to these in the preceding article, but for the convenience of the reader, shall here recapitulate them. They form the foundation of the whole theory of gravitation and physical astronomy: 1. That the planets describe elliptical orbits, each of which has one of its foci in the same point, namely, the sun's centre. 2. That the area described by the revolution of the line drawn from the planet to the sun (its radius vector) is proportional to the time occupied in its description. And 3. That the squares of the times of the revolutions of the planets are proportional to the cubes of their mean distances from the sun. This latter was discovered by Kepler in 1618.

KEPPEL, AUGUSTUS, VISCOUNT, a gallant and able English admiral, was the second son of the earl of Albemarle, and born in 1725. He accompanied Lord Anson in his celebrated circumnavigation of the world. Family interest and professional ability procured him rapid promotion, and in 1758 he commanded the expedition which captured the island of Goree. Three years later he assisted at the brilliant attack upon Belleisle, and largely contributed to its success. In 1778 Admiral Keppel was placed in command of the Channel Fleet, and on the 27th of July fell in off Ushant with a French armada of superior force, under Count D'Orvilliers. An indecisive action immediately took place, and during the night the French contrived to escape into Brest. So dubious a result excited general dissatisfaction, and Sir Hugh Palliser, Keppel's second in command, charged him with misconduct and neglect of duty. A court-martial, however, after thirty-two days' sitting, unanimously pronounced the accusation malicious and unfounded; a decision which was approved and confirmed by public opinion. Keppel, however, was deeply hurt by the treatment he had received from the government, and resigned his command. In 1782 he was raised to the peerage, and made first lord of the admiralty, an office which he filled with advantage to the service. He died, unmarried, in 1786. It may be mentioned as a proof of his popularity that the 'Keppel's Head' is still a favourite sign with many of our town hostleries and wayside inns. Burke pronounced him 'one of the greatest and best men of his age,' and he was no less distinguished for honour and generosity than for professional ability.

KERASINE (Gr. *keras*, 'a horn'), a mineral of a light yellowish-gray colour, and found in a crystallized rectangular four-sided prism. Its specific gravity is 6; and its constituents are oxide of lead, muriatic acid, and carbonic acid.

KERGUELEN'S LAND CABBAGE, the name given by Captain Cook to a remarkable plant belonging to the natural order *Cruciferae*, or cruciferous family. It is the *Pringlea antiscorbutica* of botanists. It has a great resemblance to the common cabbage, but is much larger, and has a strong perennial root stock. It is confined to Kerguelen's Land Island, and is much prized by seamen as an antiscorbutic.

KERMES (Arabic, little worm'), an insect found in the south of Europe and many districts of Asia. It is the *Coccus ilicis* of Linnæus, and was originally esteemed for affording a red and scarlet dye, to which the ancient tapestries of Flanders owe their brilliant beauty.

KERMES MINERAL, a peculiar sulphuret of antimony, formerly much used in medicine. It is obtained in the form of a brownish red powder, and is a sudorific in small doses, and an emetic in large ones.

KE'RODON, a genus of rodent Quadrupeds peculiar to South America, remarkable for the form of the molars, which all resemble each other, and are composed of two equal parts, each of a triangular or rather heart-form shape, united on the external side of the tooth, and separated on its internal side. These triangles or 'hearts' are each surrounded by their enamel, and filled with bony matter, and their separation produces an angular notch partly filled with cortical substance.

When M. F. Cuvier wrote, only one species, *Kerodon Moco*, was known, and this was discovered by Prince Maximilian of Neuwied, and noticed by him under the name of *Cavia rupestris*. The fur is ash-gray mixed with reddish yellow, and blackish above and whitish below. Size smaller than that of the guinea-pig. This species was found in the rocky places of the interior of Brazil, near Rio San Francisco.

KERRY, a maritime county of the province of Munster, in Ireland, is bounded E. by Limerick and Cork, S. by Cork and the estuary of the Kenmare, W. by the Atlantic Ocean, and N. by the estuary of the Shannon. It lies between 51° 41' and 52° 33' N. lat., and between 9° 7' and 10° 30' W. long. The greatest length from N. to S. is 54 miles, and from E. to W. 58 miles. The area is 1,186,126 acres, of which 414,614 are arable, 11,169 in plantations, 807 in towns, 32,761 under water, and 726,775 uncultivated. In 1851 the inhabitants numbered 238,239; but in 1861 they had decreased to 201,800, of whom 195,159 were Roman Catholics, and 6200 belonged to the Established Church. A large proportion of the population speak only the Irish language.

Surface.—Kerry forms the south-western extremity of Ireland. The coast, which is bordered by the Atlantic, is deeply indented by the estuary of the Kenmare River, the Bay of Dingle, and the Bay of Tralee. Many islands fringe the coast, the principal of which are the Blasquet group, Valentia, and the pinnacled Skelligs. The peninsulas between the bays form the western extremities of that mountain system, which, commencing in Waterford,

extends with little interruption across the entire south of Ireland. Beyond the range of mountains which crosses the centre of the county extends a rich and generally level country, which rises into rough land in only one direction, towards Kerry Head on the Shannon. The peninsula between the Kenmare estuary and Dingle Bay is cut by minor ranges of mountains into three principal valleys. It contains the rivers Roughty, Fartagh, Inny, Sneem, Little Blackwater, and others of smaller size. The mountain-knot called Macgillicuddy's Reeks, which extends about 10 miles in a direction S.W. to N.E., subsiding into the plain at the head of Dingle Bay, contains Carran Tual, 3410 feet above the sea-level, and the highest summit in Ireland.

Hydrography.—In a deep hollow between the south-eastern flank of this range and the group of Mangerton lies the Upper Lake of Killarney. This beautiful sheet of water, which is three miles in length by three-quarters of a mile in breadth, is inclosed on all sides by mountains from 2000 to 3000 feet in height, except at one point, towards its eastern extremity, where it discharges its waters by a tortuous course of three miles between the southern declivities of Glenna and the precipitous side of Turk Mountain. A channel leading from the Upper to the Lower Lake passes through a thickly wooded defile. About midway between the extremities of the channel a remarkable detached rock, called the Eagle's Nest, rises over the left bank to a height of 1100 feet. Emerging from this defile, the river expands into the Lower Lake of Killarney, five miles in length by three in breadth, skirting the eastern declivities of the mountain range of Tomies and Glenna. These mountains, descending abruptly to the western verge of the lake, are still the resort of red deer, and are clothed with the richest natural woods of oak, ash, pine, alder, and beech, intermixed with hazel, whitethorn, yew, holly, and arbutus, from a height of several hundred feet down to the water's edge, through a continuous distance of six miles. O'Sullivan's River, descending by a thickly wooded ravine on this side, forms a cascade 70 feet high, close to the shore of the lake. On the opposite side the low alluvial banks are everywhere broken into promontories and islands, on which the arbutus (commonly considered an exotic) grows in unusual luxuriance. The town of Killarney is situated on the plain about a mile from the eastern shore, and half a mile south of Killarney runs the Flesk, the chief feeder of the lake. Several other cascades and richly wooded promontories ornament the borders of the lake. The waters of the Lakes of Killarney discharge themselves at the northern extremity of the Lower Lake through the river Laune, which runs by a course of twelve miles into the head of Dingle Bay.

Mountain ridges, bounding valleys of greater or less width, form the distinguishing features over the greater part of Kerry. The most extensive tract of open country is near the Limerick boundary; it is drained by the rivers Feale, Gale, and Brick, which, uniting within five miles of the sea, receive the common name of the Cashen River; the united length of their courses is about 50 miles. A rough district extends from the mouth of the Cashen to Beal Point, where the estuary of the Shannon first assumes the

character of a river. The whole coast line, from the Shannon to the Kenmare, contains many good harbours, of which that of Valentia is the most westerly in the British Islands. The termini of the Atlantic submarine telegraphs are at this place.

Climate.—The climate is very moist, from the vicinity of the Atlantic, and the south-western district is much exposed to storms. In the inland parts, however, especially in the neighbourhood of Killarney, the air is mild and genial, and vegetation extremely luxuriant.

Geology.—The geological structure of the chief mountain-chains is similar to that of the mountains in the west of Cork, the main component being a red or gray conglomerate and sandstone supporting flanks of silicious flags, and overlaid in the low districts by fields of floetz limestone. The mountains of Glanbehy abound with iron ore, which was formerly smelted in considerable quantities at Blackstones, in works erected by Sir William Petty; but the supply of timber having failed, these works were given up about the year 1750. Iron has been worked in other parts, and copper and lead also exist in the county. The slate quarry in Valentia produces flags and slates to a large amount. The flagging, which is of a very superior description, is transported to London.

The soil of the south-western district, where not encumbered with bogs, is an adhesive loam, fit for the reception of corn crops. The soil of the middle district is a rich loam, producing excellent crops of grain, and when laid down in pasture, yields butter of prime quality. The northern district has a stiffer soil, more retentive of wet, and inclined to run to rushes. Cider is made in considerable quantity. The native breed of cattle is very small, but well formed, good milkers, and easily fattened. A breed of small ponies is peculiar to Kerry; they are too light for farming purposes, but answer for the saddle very well. Numerous goats and Irish cattle are pastured in the mountains, and a larger English cross-breed in the vales. The chief crops are potatoes, wheat, oats, and barley, the former of which is alone consumed by the producers, who are in general poor. The fisheries employ about 3000 men and boys.

The chief trade of the county consists in exports of agricultural produce, chiefly oats and butter. The manufacture of linen is carried on, but the quantity is insignificant. There is also a general manufacture of coarse woollens throughout the county for home consumption. Fishing is pursued extensively on the coasts.

Divisions and Chief Towns.—Kerry is divided into eight baronies and eighty-seven parishes. It is in the diocese of Limerick, Ardferit, and Aghadoe, and in the Munster Circuit. The assizes are held at Tralee. The county returns two members to Parliament, and one is returned for the borough of Tralee. The number of voters on the county register for 1869 was 5506. The following are the principal towns, with the population of each in 1861:—*Ardferit*, though now a small village, was formerly a place of importance, and the see of a bishop. A part of the ancient cathedral has been fitted up as the parish church. The village is about 6 miles N.W. from Tralee; population, 367; of the parish, 3234. *Cahiriveen*, a village situated on the southern shore of the small sea-bay called Valentia River, has a little quay and

harbour, which were constructed in 1822; population, 1802. *Castle-Island*, about 11 miles E. from Tralee, is a small but improving town. It contains a church and a Roman Catholic chapel; population, 1702. *Dingle* is on the north shore of Dingle Bay, at the bottom of a capacious and well-sheltered harbour. The town is of considerable size, situated on the slopes of the mountains which rise directly from the shores, but has a wretched appearance. It was formerly a borough, but has been disfranchised; it is still a seaport and market town. *Dingle Bay* is much exposed to the swell of the Atlantic, but the harbour is safe; population, 2260. *Kenmare*, situated at the head of Kenmare Bay, consists of one large street of neat and well-built houses. It is a market town, lying in an isolated district, has a suspension bridge across the estuary of the Roughy, and a convenient harbour pier approached by vessels of large burden. It is an extensive parish of over 22,000 acres, the total population being 3848; within the limits of the town proper only 1200. *Killarney* is situated a mile and a half from the Lower Lake of Killarney. The town consists mainly of two good streets, from which branch several poor lanes and alleys. In summer, from the influx of visitors to the lakes, the town presents an animated appearance, but in winter is very dull. Here is a venerable old parish church, a Roman Catholic cathedral for the diocese of Kerry, a nunnery with female school attached, a court-house, market-house, and assembly-room; union workhouse, hospital, and many fine hotels and reading-rooms for tourists. Killarney is 46 miles W.N.W. of Cork, and the terminus of the Cork and Killarney Junction Railway. The population of the parish, which includes a part of the lake scenery (being altogether 34,789 acres in extent), is 9570; of the town only 5204. The new cathedral (Roman Catholic) from designs by Pugin, at the west end of the town, is an imposing structure. There is also a magnificent hotel, erected by the Railway Company. *Listowel* is situated on the north bank of the Feale, about 17 miles N.N.E. from Tralee; it is an improving town, and a place of considerable thoroughfare. A new bridge has been made across the Feale; population 2273. *Tarbert* is situated on an inlet of the estuary of the Shannon, called Tarbert Bay, which affords good anchorage; population, 857. *Tralee*, the chief town and port of the county, where the assizes are held, is situated on a flat tract of land which extends along the shores at the head of Tralee Bay. It is about a mile from the sea, but is connected with it by a ship canal. Tralee is one of the most thriving towns of the south of Ireland. Its exports, imports, and general trade have much increased of late years. It is well built and contains a handsome court-house, a county prison adjoining, a church, two large Roman Catholic chapels, meeting-houses for Presbyterians, Independents, and Methodists, a county infirmary, fever-hospital, and infantry-barracks. It has also two nunneries, a county court-house, lunatic asylum, and custom-house. The port has a good trade in grain and flour. Vessels of 300 tons can discharge their cargoes by means of the ship canal mentioned above. The number of entries in 1867 was 204 (52,255 tons), and the clearances 52 (6802 tons). The customs revenue in 1868 amounted to 13,376*l*. In the vicinity is a

spa, resorted to by invalids. *Tralee* is a parliamentary borough, and had 263 electors in 1869. The corporation is now extinct, and its property vested in the lighting and cleansing commissioners; population, 10,191. *Valentia*, an island and parish separated from the mainland by a strait $1\frac{1}{2}$ miles in breadth, is the most westerly point in Ireland, and has become widely known as the place where the homeward-bound American mail packets first touch, and also as the *termini* of the Atlantic telegraphs; population, 2920.

History.—Kerry originally formed part of the kingdom of Desmond, or South Munster, of which the Mac Carthies were sovereigns. About 1177, part of the county came into the hands of Maurice Raymond, from whom the Fitzmaurices, lords of Kerry, draw their pedigree, and the barony of Clanmaurice takes its name. It was made a shire by King John in 1210. Soon afterwards the Fitzgeralds established themselves in the south of the county, and, as earls of Desmond, exercised powerful influence until the time of Elizabeth, when their authority was put an end to, and their estates confiscated. From 1641 till 1691 there was almost a constant series of insurrections and confiscations.

Kerry contains several monuments of a very remote antiquity, of which the most remarkable are the Cyclopean stone fortresses of Cahirconree, Staigue, and Cahir Donnell; and the sepulchral stones with Celtic inscriptions in the neighbourhood of Dingle. There is a round tower at Rattoo, one in an island in Loch Currane, and part of another at Aghadoe. There are also the remains of thirteen religious houses and thirty feudal castles.

KERSEYMERE. [WOOLLEN AND WORSTED MANUFACTURES.]

KERTCH, a seaport town of Russia, situated on the south-east of the Crimea, about eight miles west of Yenikale, and celebrated as the place against which an Anglo-French expedition was sent during the siege of Sebastopol in 1854–55. The squadron sailed on the 24th of May, 1855. It was garrisoned by the Russians; but on the approach of the enemy they blew up the magazines, destroyed the stores, and vacated the town. After this the expedition captured Yenikale, and entered the Sea of Azoff, when Arabat, Genitch, and other places were attacked, and immense supplies of stores, as well as numerous vessels laden with grain, were destroyed. Kertch was once the residence of Mithridates, and is the site of the ancient Panticapeum, the seat of the Bosporean kings. Before the Russian war it was the most important port of the Crimea, and its trade is still considerable. The exports in 1866 were valued at 70,890*l*., consisting principally of corn, salt, petroleum, and hides. The imports amounted to 12,363*l*. More than one-half of the foreign commerce is with Great Britain. The population in 1867 was 19,682.

KESTREL (*Falco tinnunculus* of Linné), the name of a well-known bird of prey belonging to the family *Falconidae*. It is also named the *Windhover* from the manner of its flight. In the male the head, hind-neck, and tail are a dull grayish blue colour. The tail is marked by a broad subterminal black bar. The wings, when closed, are about two inches shorter than the tail. The feathers of this

back and the wing-coverts are a pale red with triangular black spots. The feathers of the breast and belly are yellowish red, with longitudinal linear and round spots. In the female all the upper parts are light red, with transverse spots of dark brown. The lower parts are paler, with oblong dark blotches. The kestrel is a harmless bird. Its chief food is field mice and large beetles. The female lays from three to five eggs, which are roundish, pale orange-red, irregularly patched. The young when they leave the egg are of a dirty white colour, which in a day or two becomes a bright white.

KESWICK. [CUMBERLAND.]

KETCHUP, a sauce made principally of mushrooms, but also of walnuts and tomatoes.

KETTERING. [NORTHAMPTONSHIRE.]

KETTLEDRAW, an instrument used principally by cavalry and artillery bands, its shape rendering it more convenient than the ordinary cylindrical drum for use on horseback. It is made by stretching vellum over the circular edge of a hemispherical vessel of brass or copper.

KEUPER, in Geology, the German term for the upper portion of the new red sandstone formation, one of the members of the Triassic system of rocks. It takes its name keuper, or copper, from the variegated copper-bearing marls, sandstones, &c., of which it is composed. It is from 700 to 100 feet thick. In this country it is represented by the saliferous and gypseous shales and sandstones of Cheshire, and contains rock-salt and gypsum.

KEW. [SURREY.]

KEY, in Music, is the particular diatonic scale, whether major or minor, in which a composition begins and ends, and which more or less prevails in a given piece of music.

The diatonic scale may commence on any note, and that chosen, called the *Key Note*, governs the progression of the other notes. [SCALE.] If a composition begins and ends in a scale in which neither sharps nor flats are used, it is in the key of c, the distinctive term *natural* being understood. When three flats are placed at the clef, and the last and lowest note in the piece is $\epsilon \flat$, the key is $\epsilon \flat$; and so in other cases.

As any note in the diatonic and chromatic scales may be taken as a key note, it follows that there are twelve keys in the major mode and twelve in the minor; for each scale may have either a major or a minor 3rd. Hence arise twenty-four keys. But as three major and three minor keys have two designations each (as for example, $\alpha \flat$ and $\epsilon \sharp$, which are merely two different names for the same key or note), there are in name thirty different keys, and as many signatures are in actual use.

KEY or KI ISLANDS are a group of considerable extent in the Indian Archipelago, situated between $5^{\circ} 20'$ and $6^{\circ} 30'$ S. lat., and between $132^{\circ} 30'$ and $138^{\circ} 40'$ E. long. Three islands are rather large, and called Great Key, Little Key, and Key Watela. The number of the smaller ones is not known, as they are rarely visited by Europeans. The population is from 8000 to 10,000, many of whom are Mohammedans. The Great Key is about 45 miles in length. The three larger islands rise to a moderate elevation above the sea, and all the heights are overgrown with forest trees, which constitute one of

the principal sources of wealth to the inhabitants, who are engaged in shipbuilding to a considerable extent.

KHAIBAR, a town of Arabia, 100 miles N.N.E. of Medina, is the capital of an independent Jewish territory. It was captured in 628 by Mohammed, who here received from a Jewess the poisoned egg which ultimately cost him his life.

KHAMSIN, the name of a hot south wind or blast, which begins to blow in Egypt soon after the vernal equinox. It continues at intervals for a period of about fifty days, as the term implies, and is somewhat similar in its destructive effects to the simoom, or sirocco, so prevalent in the desert regions of the East.

KHAN, a word of Mongol or Turkish extraction, said to mean 'great and powerful lord,' was employed by the nations of central Asia to express the full extent of royal power. It was assumed by Gengis when he became supreme ruler of the Mongols and Tartars, and was adopted by all his successors. The earlier monarchs of the Ottoman empire were also distinguished by this title. The word is used in Persia in a more restricted sense, being applied to the governors of provinces.

KHARKOV. [SLOBODE-UKRAINE.]

KHARTOUM. [SENNAR.]

KHAYA, a genus of plants of the natural family of *Cedrelaceae*, which is often made a tribe of the *Meliaceae*. Khaya contains only a single species, *K. Senegalensis*. It forms one of the largest and handsomest of the trees which are found along the banks of the Gambia and in the valleys near Cape Verde. It is valuable for its wood, and medicinally for its bark.

KHERSON, or CHERSON, a government of European Russia, lying between $46^{\circ} 12'$ and $49^{\circ} 4'$ N. lat., $29^{\circ} 10'$ and $34^{\circ} 5'$ E. long., is bounded N. by Podolia, Kieff, and Pultawa, E. by Ekaterinoslaf, S. by Taurida and the Black Sea, and W. by Bessarabia. Its area is 27,713 square miles, and its population 1,027,459. Its length from E. to W. is 240 miles, and its average breadth from N. to S. is about 140. The province, which consists of an immense plain, lies between the Dnieper and the Dniester, which respectively bound it on the east and west. The central parts are drained by the Bog [BOG], the Ingul, the Inguletz (a feeder of the Dnieper), and by several smaller streams. The north of the country is diversified by some hills, which are covered with forests. The rest is a treeless steppe overgrown with tall grass, which the great heat of summer withers; vegetation does not revive till the autumn. In the interior the soil is a gray clay mixed with sand, which produces rich pasture. Here and there are heaths, and in the lower parts swamps: on the coast there is a red ferruginous earth, which produces little besides saline plants. There is a great scarcity of spring water in the steppes. The climate is very variable; in summer the heat is from 85° to 90° of Fahr. A dark yellow sky, a wind which raises the dust in clouds, and an immense torrent of rain, are the usual precursors of a thunder-storm, which is awful beyond conception. The nights are always cool. The winter is cold: most of the rivers freeze over, though but for a short time. Agriculture is in a backward state; the breeding of cattle and sheep is the chief

occupation of the population. Corn, hemp, flax, tobacco, liquorice, saffron, and mustard are grown. The vine is cultivated, and much attention is paid to horticulture. Oxen and buffaloes are numerous, and used for draught; the horses (of which many are wild) are slight, but very spirited and swift-footed; the breed of sheep has been much improved by crossing the common stock with merinos. Wolves, wild cats, bustards, gray partridges, ortolans, snipes, &c., abound; the country is infested by locusts, large rats, snakes, scolopendræ, lizards, and swarms of gnats. The fisheries on the sea coast and in the rivers are important. The minerals are—fine potter's clay, freestone, slate, chalk, talc, saltpetre, agates, and garnets. The province is well situated for trade. The foreign commerce of the country is very important and rapidly increasing. Manufactures of cloths, tallow, leather, butter, cheese, and caviare, are carried on, partly by Swedish, German, and other colonists, the population consisting of a great intermixture of races.

The chief towns are Kherson, Elizabethgrad, Nicolaiev, and ODESSA.

Kherson, a large, well-built, fortified town, with 40,402 inhabitants, is situated on the right bank and near the mouth of the Dnieper, which forms a good harbour. It is the seat of the governor of the province, and was formerly important on account of its great naval dockyards, arsenal, and foreign trade. But unhealthiness of site, and the difficulty experienced by large vessels in crossing the bar at the entrance of the harbour, have greatly contributed to its decline in favour of Odessa, although a good trade is still carried on in linseed, wheat, ropes, tallow, and wool, the exports amounting to about 1,000,000*l.* annually. Three miles distant are the tomb and cenotaph of Howard the philanthropist, who died here in 1790.

Elizabethgrad, situated in the interior on the Ingul, has strong fortifications, military magazines, a large hospital, and about 15,000 inhabitants. It was established with great pretensions by Catherine II., but has never prospered.

Nicolaiev, a well-built town, situated at the confluence of the Ingul and the Bog, contains 33,504 inhabitants. It is the seat of the admiralty that directs all the Russian naval operations on the Black Sea. The town is strongly fortified, and has several fine buildings, among which are remarked the principal Greek church, the town-house, the custom-house, the admiralty buildings, and the shipbuilding yards. It is a place of considerable trade, and has numerous schools and other institutions for the education and improvement of persons devoted to naval and military pursuits. It was founded in 1790, and since the fall of Sebastopol has been the chief naval station of Russia in the Black Sea.

KHIVA or **KHYVA**, a country of Independent Turkistan, on the east of the Caspian Sea, extends from lat. 37° 45' to 44° 30' N., and from long. 50° 30' to 63° E. The population consists mostly of wandering tribes, and is estimated to number 200,000. The surface is almost entirely a sandy desert, but along the banks of the Oxus (which flows through the eastern side), and the canals connected with it, there are many fertile tracts. In these places the vine is cultivated, and wheat, millet, barley, fruits, linseed, cotton, flax, and some rice, are grown. The

breed of horses is good, and sheep and goats abound. Camels are the ordinary beasts of burden. About 2000 of them go annually to Orenburg, Astrakhan, and Cabool with agricultural produce, silk and cotton fabrics, and yarn, to be exchanged for the products of Russia and the West, which are brought in boats across the Caspian Sea. Some shawls are made by the females and exported; but agriculture is the principal occupation of the settled inhabitants, and is in a very advanced state. The population is very mixed, the dominant race being the Uzbeks, as in Bokhara. *Khiva*, the capital, is situated in 41° 30' N. lat., 60° 18' E. long., in an irrigated plain near the Oxus, surrounded by numerous gardens. It is the chief seat of trade, though the only stone buildings are three mosques and a caravanserai. The population is given as about 12,000.

KHOKAN, a khanat of Central Persia, in Independent Turkistan, between lat. 40° and 45° N., long. 67° and 75° E., bounded by Chinese Turkistan, South Bokhara, &c. The surface is mountainous, pasturage plentiful, live stock numerous, and wool is an important article of export. The products comprise corn, cotton, silk, and fine fruits, including the apricot, apple, pear, almond, and melon, with coal, copper, iron, &c. The chief articles of manufacture are embroidered silks, cotton stuffs, cochineal, and sandalwood. Shawls are imported from Cashmere and Balkh, the rest of the trade being chiefly with Budakshan and Russia. The khan maintains an army of about 10,000 men. Russia, which is steadily pursuing her advance towards India, has, by arrangement with the king of Bokhara, obtained 700 villages and towns in the khanat, and it is probable that at no distant period Khokan will be united to Russia. The principal towns are Khokan, Khojend, and Tashkend. Population estimated at 150,000 to 180,000. *Khokan*, the capital, is reported to be about half the size of Bokhara, with a population of from 30,000 to 50,000. Its vicinity is fertile and cultivated. The chief buildings of the town are the khan's residence, bazaars, mosques, and public schools.

KHORASAN. [PERSIA.]

KHOSRU I., called Chosroes by the Greek writers, but more commonly known in the East by the name of Nushirwan, 'noble soul,' succeeded his father Kobad in the kingdom of Persia in 531. He divided the empire into the four great provinces of Assyria, Media, Persia, and Bactriana, and established a vizier over each. In the course of a few years he extended his dominions as far as the Indus. He died in 579, after a reign of forty-eight years, and was succeeded by his son Hormisdas IV.

The virtues, and more particularly the justice, of this monarch, form to the present day a favourite topic of Eastern panegyric. His reign forms an important epoch in the history of science and literature: he founded colleges and libraries in the principal towns of his dominions, and encouraged the translation of the most celebrated Greek and Sanscrit works into the Persian language.

KHOSRU II., the grandson of Khosru I., was elevated to the throne of Persia in 590, on the deposition of his father Hormisdas. In the first year of his reign, Khosru, to escape from the treachery of Bahram, who seized upon the royal power, took

refuge in the dominions of Maurice, the emperor of Constantinople, who assisted him to defeat his rival and obtain repossession of the sovereignty; the assistance was, however, purchased by the surrender of some important towns of Mesopotamia and the payment of a large sum of money. During the life of Maurice peace was preserved between the two nations; but on his assassination by Phocas in 602, Khosru took up arms to revenge his death, as he pretended, and in the space of fourteen years subdued almost all the provinces of the Greek empire. Khosru at length, in 621, dictated the terms of an ignominious peace to the Emperor Heraclius, who had hitherto made very few efforts for the defence of his dominions, but who rejected these terms, and in a series of brilliant campaigns (622-27) recovered all the provinces he had lost, and repeatedly defeated the Persian monarch. Khosru was murdered in 628 by his son Siros.

KHYBER PASS. [AFGHANISTAN.]

KIACHTA, a town in the Russian government of Irkutsk, in Siberia, is situated in 50° 20' N. lat., 106° 40' E. long., in a sterile country, 2480 feet above the level of the sea, on a small stream also called the Kiachta. It consists of two separate parts—the fortress, called Troitsko-Sawsk (population about 5000), where the custom-house, the imperial offices, and the military government are established; and the lower town, or Kiachta, which is nearly two miles farther south, and where the Russian merchants live; the population is only 285. The commerce of this place with *Maimaitchin*, the Chinese emporium, which is less than a mile from the lower town, has risen to great importance in modern times. The Russians bring to Kiachta furs of the sable, black fox, and ermine; hides, leather, woollen cloth, and other coarse woollen fabrics; glass, looking-glasses, cattle, and large quantities of bullion. They receive in return from the Chinese, manufactured silks and cottons, musk, rhubarb, tobacco, china, furniture, and several kinds of toys; but the principal commodity taken in exchange is tea. At the Kiachta December fair about 60,000 chests, or 4,200,000 lbs., of fine Pekoe are annually purchased by the Russians, in addition to a still larger quantity of an inferior kind, much of which is consumed by the Siberians and nomadic Tartars. There is here an academy for the Chinese language.

KIDDERMINSTER. [WORCESTERSHIRE.]

KIDNAPPING is defined to be the stealing or conveying away of a man, woman, or child, and is an offence at common law, punishable by fine and imprisonment, and until the abolition of that mode of punishment by 1 Vict., c. 23, by pillory. The 24 & 25 Vict., c. 100, provides for the offence of child-stealing as felony. In Scotland this crime is known by the name of *plagium*, and was in former times punishable by death as treason—the detention of the king's lieges being regarded as an encroachment upon the royal prerogative. The forcible abduction of women, and of voters at elections, are crimes at common law, and punishable with an arbitrary pain.

KIDNEY-BEAN. [BEAN.]

KIDNEYS are two glands lying in the lumbar region, on each side of the spinal column. They are composed of numberless and delicate tubular ramifications, on whose walls there is a fine net-work of

capillary arteries and veins, and which are all collected into one mass of a firm fleshy consistence, inclosed in a fibrous capsule.

The ureter, through which the urine secreted by the kidney is conveyed to the bladder, dilates at its extremity into a wide pouch, the pelvis of the kidney, which is divided into several portions, called calyces. Into each calyx a nipple-like process, or papilla, projects, at whose extremity there are several minute orifices, each opening into a very fine canal, which, as it is continued into the substance of the kidney, ramifies and becomes tortuous. On all these canals, or tubuli uriniferi, minute blood-vessels ramify, which with a number of rounded bodies called the corpuscles of Malpighi, secrete the urine, which is conveyed from the tubuli into the calyces, and from them through the pelvis and the ureter into the bladder.

Diseases of the Kidneys.—The principal disease to which the kidneys are liable is that which gives rise to the formation of calculi. [*Calculus, Renal.*] Sometimes the stone is retained in the pelvis of the kidney, where, by continued depositions, it may increase till it completely fills the pelvis and calyces; but more frequently it passes through the ureters into the bladder, producing in its passage violent spasmodic pain in the loins, sickness and nausea, hæmorrhage, &c. This affection is the most common cause of inflammation of the kidneys (nephritis), from which abscess and other morbid alterations may result. Chronic inflammation seems to be the most frequent cause of a peculiar alteration in the structure of the kidneys, particularly described by Dr. Bright, of which the chief characters are, the interstitial deposition of a pale yellowish and firm substance, and a granular or tuberculated form of the surface of the kidney, with a great decrease of its vascularity. This condition comes on in hard drinkers, and after the scarlet fever; it usually produces dropsy, and is indicated by a dull heavy pain in the loins, a bloated expression of the countenance, a hard pulse, and the secretion of so large a quantity of albumen with the urine that it coagulates on being heated, or on the addition of a little nitric acid. Suppression of urine may be the ultimate result of obstruction from calculi in the ureters, or it may occur as an idiopathic disease. It is a condition of great danger. The kidneys are also subject, in common with other organs, to the deposition of various morbid substances, as cancer, fungus, hæmatodes, melanosis, tubercle, &c. But the diagnosis of all the chronic affections of this organ is extremely obscure, the principal indications of each being the same, viz., the dull heavy pain in the loins, dropsy, and sometimes hæmaturia.

KIEL, a seaport and the chief town of Holstein, is beautifully situated on a bay of the Baltic, which forms an excellent harbour, in 54° 10' N. lat., 10° 8' E. long. It is 53 miles by railway from Altona and Hamburg, and has 17,543 inhabitants. The town, which is surrounded with walls pierced by five gates, is pretty regularly built, with straight, well-paved streets. It has a university, founded in 1665, connected with which there is a library of 80,000 volumes, an observatory, and botanic garden. The manufactures consist of iron goods and machinery, linen, hats, tobacco, refined sugar, &c.; shipbuilding is carried on. The trade in corn, dried herrings, and dried sprats, is considerable, and has much increased

since the completion of the Kieler Canal, which joins the Baltic and the German Ocean, and enters the harbour of Kiel. Steamboats ply regularly to Copenhagen, Aalborg, &c. The chief public buildings are the cathedral church of St. Nicholas, of the thirteenth century, a handsome palace, the public baths, and grammar-school. The castle has a sculpture gallery, with copies of the best works of art. The charming environs attract inland visitors in summer, intent on recreation and sea-bathing. Kiel became part of Prussia, with Holstein, after the Danish war in 1864.

KIEV, or KIEFF, a government of Russia in Europe, lying between $48^{\circ} 30'$ and $51^{\circ} 30'$ N. lat., $28^{\circ} 40'$ and $33^{\circ} 25'$ E. long., is bounded W. by Podolia and Volhynia, N. and N.E. by Minsk and Tchernigof, E. by Pultawa, and S. by Kherson. It has an area of 19,656 square miles, and a population of 1,944,334. The surface is in general flat, with a few undulations which follow the course of the rivers. The land in the north of the government of Kiev is extremely rich and fertile; in the south the soil is poorer; but still there are here also tracts of luxuriant corn fields and good pastures. The whole government belongs to the basin of the Dnieper, which forms the north-eastern boundary for nearly 250 miles. [DNEPER.] The interior is drained by the numerous feeders of the Dnieper from the left bank, the principal of which are the Pripetz, the Teterer, the Irpen, and the Ros, the latter of which rises in the west of the province, and dividing into two arms, forms with the Dnieper a large island. The climate is mild and dry, and adapted to all the productions of the temperate zone, though no vines are cultivated. The rivers usually freeze in December, and thaw in February; the north wind is always severely felt in winter. The heat is great in summer, during which season rain seldom falls. Locusts often do great injury to the growing crops.

Agriculture is the chief employment of the inhabitants, and wheat is extensively exported to Odessa. The soil produces all kinds of corn, pulse, millet, hemp, fruits, flax, hops, and tobacco. Cattle are numerous and of good breed; horses are small; swine are kept in great numbers; sheep are scarce. The forests produce excellent timber, and large quantities are annually floated down the Dnieper to the ports of the Black Sea. Among the wild animals are foxes, wolves, bears, deer, &c. The minerals are clay, lime, chalk, millstone, and bog iron. There are numerous distilleries, and beet-root sugar, tobacco, cloth, china, and delft are manufactured. The trade consists in the exportation of the produce of the province, and the importation of salt, metal, wine, manufactured goods, and colonial produce.

KIEV, the capital of the government, is built on a hill on the right bank of the Dnieper, in $50^{\circ} 27'$ N. lat., $30^{\circ} 27'$ E. long., and has more than 60,000 inhabitants. The town consists of four distinct parts—the old convent and fortress of Petchersk, in which are the celebrated catacombs, containing the bodies of 118 saints; Old Kiev, which contains the fine cathedral of Santa Sophia, and is the residence of the Russian archbishop; Podol, containing most of the private houses, numerous churches, an imperial palace and town-hall; and Vladimirstadt, which was built by Catherine II. Kiev is the seat of the governor-general of Little Russia, capital of a

Greek eparchy, and has a civil and criminal court. It is 670 miles S. of St. Petersburg, and 490 S.W. of Moscow: is fortified, and has an arsenal. Besides its cathedral, churches, convents, and a Greek ecclesiastical academy, Kiev has a university, founded in 1834, called St. Vladimir's University, which is frequented by students from the governments of Kiev, Podolia, and Volhynia. Kiev contains the oldest Greek ecclesiastical academy in Russia, which was founded in 1588. The university has cabinets of medals, mineralogy, zoology, and botany, and most of the collections transferred from the old University of Vilna. There is also a Russian theological seminary, with a large library, two gymnasiae, and an establishment for the education of the daughters of nobles.

Kiev is one of the oldest towns in Russia, and was its capital for three centuries. In 980 the Grand Duke Vladimir here embraced Christianity and cast Perune, the thunder god (who occupied a place in the Slavonic mythology analogous to that of Zeus among the Greeks, and Jupiter among the Romans), into the sea, after the image had been soundly cudgelled by twelve stout men. The great point of attraction in Kiev is the catacombs, previously alluded to. They consist of two caverns, excavated in the precipitous cliff which faces the river. They were once occupied by living, and have since accommodated the remains of departed, monks and saints. The bodies are arranged along the sides in open coffins, but enveloped, like Egyptian mummies, in wrappers, so that no part is left visible. But the stiffened hands are so arranged as to receive the kisses of devotees, and on the breasts are written the names of the deceased, with occasionally a brief record of their lives. Kiev is thus the Jerusalem and Mecca of Russia, and is annually visited by multitudes from all parts who seek an interest in the intercession of the defunct. They perform the whole journey on foot, seldom sleep under a roof, and depend upon precarious charity for subsistence.

Kiev is not an industrial but a commercial centre, and its fairs are amongst the largest in the Russian empire. The Dnieper is here crossed by a remarkable suspension bridge, the work of an English engineer (Mr. Vignolles). Nearly 3000 tons of iron were employed in its construction, all of which, as well as the requisite machinery, were wrought in England. Fifteen vessels conveyed this material to Odessa, and it was then transported in bullock waggons over the steppes.

KILDA, ST., the most western of the Hebrides, is situated in $45^{\circ} 49'$ N. lat., $8^{\circ} 32'$ W. long., and consists of an uneven mountain-ridge, the most elevated point of which rises 1380 feet above the sea-level. The greatest width of the island is about 2 miles, and the length 3 miles. The population in 1861 was 78, who inhabit a village in the S.E., and live in a great measure on the eggs of sea-birds, which are exceedingly abundant. They are also occupied in rearing cattle and sheep, and in fishing.

KILDARE, an inland county of the province of Leinster, in Ireland, is bounded N. by Meath, E. by Dublin and Wicklow, S. by Carlow, and W. by Queen's County and King's County. It is situated between $52^{\circ} 50'$ and $53^{\circ} 25'$ N. lat., and between $6^{\circ} 27'$ and $7^{\circ} 10'$ W. long. Its greatest length from

N. to S. is about 40 miles, and its greatest breadth E. to W. 27 miles. The area is 418,436 acres, of which 356,787 are arable, 51,854 uncultivated, 8288 in plantations, 490 in towns, and 1017 under water. The population in 1851 was 95,724; in 1861 it had decreased to 90,946, of whom 79,121 were Roman Catholics, and 11,817 Protestants.

Surface and Soil.—The surface is more level than that of any other county of Ireland. The only considerable elevations are the hills of Rathcoole, which form the western extremity of the range of the Dublin mountains, and a detached group which occupies part of the southern margin of the Bog of Allen, in the central northern division of the county.

An open table-land divides the middle and southern parts of Kildare into two districts, of which the one slopes gradually towards the river Liffey on the east, and the other towards the river Barrow on the west. The west district is divided into three open vales by low ranges of undulating ground extending in parallel directions from the central table-land towards the south-west. The most northern of these vales contains the rivers Feagile and Little Barrow; but the chief rivers of the county are the Barrow and the Liffey. That part of the valley of the Liffey which is included within this county is formed by the western slope of the Dublin mountains on the one side, and by the subsidence of the table-land of Kildare on the other. The country in this neighbourhood is in a high state of cultivation, and much of it in demesne. The western bank of the river particularly, from the point where it enters the county to Leixlip on the Dublin boundary, is almost wholly occupied by a succession of demesne lands, including numerous residences of the best class. The river Boyne rises in the north of the county.

The common called the *Curragh of Kildare*, a tract 4858 acres in extent, is the property of the Crown, and is scarcely to be matched for the excellence of its turf and the richness of its verdure. Here is a large permanent military camp, where the prince of Wales went through the usual routine of camp life for some months in the year 1861. Most of the Curragh is used as common pasture ground; but it also contains a well-known race-course—the Newmarket of Ireland—and a part of the Bog of Allen.

The north-western part of the county, extending from the Bog of Allen to the Boyne, is open and chiefly in pasture. Besides the Royal Canal, the Grand Canal, and their branches, which connect it with Dublin, Waterford, and the Shannon, the county is intersected by the Great Southern and Western railways, which pass through or near the towns of Naas, Newbridge, Kildare, Monasterevan, and Athy. Large quantities of turf are sent to Dublin by the canal.

Climate.—The climate, from the quantity of boggy surface exposed (about 50,000 acres in all), is more moist than that of the neighbouring counties on the north and south. In the central district the air is pure and keen, and milder and more salubrious in the valleys of the Liffey.

Geology.—The clay-slate, which flanks the granite axis of the Dublin and Wicklow mountains, occupies about one-fourth part of the surface of Kildare. The granite tract of Carlow extends into the south-

eastern extremity of this county. The remainder of the county is occupied with the floetz limestone of the great central plain, broken only by the group of Dunmurry and the Hill of Allen. The latter is composed of a mass of granular compact greenstone and greenstone-porphry protruded through the floetz limestone.

The soil is generally a rich loam, resting on limestone or clay-slate. There are rich fattening lands in the baronies of Carberry, Clane, and North and South Salt, which occupy the north-western and north-eastern portions of the county. An improved system of agriculture has been introduced by the resident proprietors, and is practised to some extent by the smaller farmers. The general crops are wheat, oats, and barley. The best English breeds of cattle have been introduced. The minerals of the county are unimportant.

The only manufactures carried on are of paper, cotton, and woollen, but only to a very limited extent.

Divisions and Chief Towns.—Kildare is divided into 14 baronies and 116 parishes. It is in the Home Circuit. The assizes are held at Naas. Kildare is in the united diocese of Dublin, Kildare, and Glandelagh, and contains the Roman Catholic College of Maynooth. Until 1869 the latter was aided by an annual parliamentary grant of 28,500*l.* Of the population, only 10,439 belong to the Established Church. The number of electors on the county register in 1869 was 2999.

Kildare is within the Dublin, or Northern Military District; and there are barracks at Athy, Naas, Newbridge, and the Curragh. The latter is the headquarters of the district, and can accommodate 10,000 men. The county returns two members to Parliament. There are no parliamentary boroughs. The following are the principal towns, with the population of each in 1861:—*Athy*. [ATHY.] *Celbridge*, situated on the northern bank of the Liffey, here crossed by a bridge, 13 miles W. from Dublin, contains a church and Roman Catholic chapel, a workhouse, county hospital, and woollen factory, and is the head of a poor-law union. Population, 1592. *Kildare*, 32 miles S.W. from Dublin, is a small and poor town, which contains a Roman Catholic chapel, nunnery, and friary. Population, 1399. The bishopric of Kildare is attached to the archbishopric of Dublin. It has a station on the Great South-Western Railway, and the celebrated Curragh races take place in April, June, September, and October. The town suffers greatly from want of water. The Protestant cathedral, which is partly ruined, contains the burial vault of the earls of Kildare. Kildare is also the see of a Roman Catholic bishop, and has, besides, a county infirmary, market-house, and jockey club. Kildare was once of great importance; and notwithstanding its present decayed appearance, is exceedingly interesting for its antiquities. *Leixlip*, a small town beautifully situated on the Liffey, 11 miles W. from Dublin. Population, 788. The Midland Great-Western Railway Company have a station here. *Maynooth*, 15 miles W. from Dublin, is a small town, consisting of a single street, and having a population of 1497. Maynooth is chiefly distinguished for the Royal College of St. Patrick, founded in 1795 for the education of the Roman Catholic priesthood. The present building, erected in 1849, after the designs of

Pugin, is a striking Gothic edifice. The grounds occupy 80 acres. The college accommodates about 500 students, 250 of whom are maintained free. The academical year embraces ten out of the twelve months, and the students usually remain eight years. There is also a convent at Maynooth. *Naas*, which is the assize town for the county of Kildare, is 20 miles S.W. from Dublin. A branch of the Grand Canal passes it, and it is a place of considerable traffic. There are a county court-house and a new gaol, infantry barracks, a modern church in the pointed style, a large modern Roman Catholic chapel, a convent, diocesan and national schools, a dispensary, county fever hospital, and union workhouse. Population of the parish, 4124; of the town, 2966. Next to Athy, it is the largest place in the county. The principal street is about half a mile in length. The Great South-Western Railway passes near here.

History.—In the ancient division of Ireland the present county of Kildare was divided among many families. The Fitzgeralds became the ruling family in Kildare about the close of the thirteenth century, and maintained their authority, with many fluctuations, to the sixteenth. This county was the theatre of various military operations during the wars which succeeded the rebellion of 1641. The Kildare family were active in bringing about the Restoration, and espoused the Protestant cause in the subsequent wars of the Revolution of 1688.

Many earthen works, partly military and partly sepulchral, remain in this county. Numerous sepulchral mounds may be seen on the Curragh, and pillar-stones of large dimensions in other places. Round towers exist at Kildare, Taghadoe, Kilcullen, and Castledermot. There are also ruins of numerous religious houses in this county. At Castledermot, Moone, and Old Kilcullen are stone crosses ornamented with curious sculptures. Seventeen ancient castles are still standing, of which those of Kilkea, Donadea, and Leixlip are still inhabited.

KILFENORA, formerly a bishop's see in the archiepiscopal province of Cashel, in Ireland, is now in the archbishopric of Dublin and Cashel, and is included in the united bishopric of Killaloe, Kilfenora, Clonfert, and Kilmacduagh.

KILKENNY, an inland county of the province of Leinster in Ireland, is bounded N. by Queen's County, E. by Carlow and Wexford, S. by Waterford, and W. by Tipperary. It lies between $52^{\circ} 13'$ and $52^{\circ} 53'$ N. lat., and between $6^{\circ} 55'$ and $7^{\circ} 38'$ W. long. Its greatest length N. to S. is about 45 miles; its average breadth is about 24 miles. The area is 796 square miles, or 509,732 acres; of which 470,102 were arable, 21,126 uncultivated, 13,899 in plantations, 3056 under water, and 1549 in towns and villages, in 1865. The population in 1861 was 124,515; of whom 118,125 were Roman Catholics, and 5992 Protestants of the Establishment. The inhabitants in 1851 numbered 158,748. There were 5159 voters on the county register in 1869.

Hydrography and Surface.—The navigable rivers Barrow and Suir form the greater part of the eastern and the whole of the southern boundary of Kilkenny, and the partly navigable Nore traverses its entire length from N. to S.E. The northern part of the district between the rivers Nore and Barrow is occupied by a mass of high lands, spreading into

numerous lateral groups, whose general direction is from N.N.E. to S.S.W. These valleys are watered by the rivers before named, and by the minor rivers Dian, Dineen, Dubhglass, Owenree, Munster River, and Clodagh. The ranges of hills have various designations in different parts of the county; such as Castlecomer hills, Slievenamon range, Brandon Mountain, 1696 feet high, Coppinach range, Walsh mountains, and King's Mountain. Several of the summits rise to an elevation of 1000 feet. The county contains a considerable number of small towns and villages; and in the most picturesque spots are many beautiful mansions and parks. Five miles south-east of Ballyragget is the remarkable cave of Dunmore. The entrance is by a picturesque hollow clothed with brushwood, at whose extremity the cavern opens by a natural arch 50 feet high. There are several chambers within, incrustated with stalactites and traversed by a subterranean stream. Beyond the central district nearly all the southern part of the county is occupied with hilly tracts, connected on the east with the granite group of Carlow, and on the west with the range of Slievenamon. A tongue of alluvial land called the Roer, extending above 2 miles in length, occupies the south-eastern extremity of the district at the point of junction of the Nore and Barrow. With the exception of this spot the western bank of the Barrow from Graigue to the Nore is precipitous, and in some places clothed with natural wood. The space between the southern declivities of the Walsh mountains and other groups ranging towards Tipperary and the Suir is occupied to a breadth of from 2 to 5 miles by a level tract of rich land. The river Suir is navigable for vessels of 120 tons up to the bridge of Carrick. At the bridge of Waterford it is in some places 8 fathoms deep at low water. The Barrow is navigable to a considerable distance from its mouth. The general slope of the surface is to the S.E., which is the best aspect both for sun and shelter. Surface waters run off rapidly, and there is very little bog; the air is consequently dry and healthy.

Geology.—Except the mountain groups of the S., the entire surface of Kilkenny is occupied by the limestone of the central plain, overlaid in the hilly districts N. of Kilkenny city by shale and sandstone. The coal formations are nearly co-extensive with the hilly districts; the limestone, where it forms the surface-rock, spreads into undulating plains sweeping round the high grounds, and occupying the intermediate valleys. These anthracite coal-beds would be of great commercial value, if the natural resources of Ireland were better developed. The general colour of the limestone is a bluish gray. Near Kilkenny it passes into a fine black marble, containing a great variety of shelly impressions. These beds are extensively quarried, and the blocks dressed on the spot by a saw-mill driven by the Nore. The marble, which is sometimes procured of a jet-black, is manufactured into chimney-pieces, tombstones, &c.: it bears a very high polish, and can be raised in large blocks. Marl is found in large deposits in various parts of the county. The mountain tract occupying the S. of Kilkenny, with the exception of the primitive group of Brandon, consists of a nucleus of clay-slate surrounded by sandstone. There are many chalybeate springs in the county.

Produce and Manufactures.—Only a small portion of Kilkenny is unfit for tillage. The hills of the northern districts are round-backed and accessible; and the Walsh mountains are mostly pasturable. The group of Brandon is the only considerable extent of rough land in this county. In the coal-tract the soil is a moory turf lying over a stiff whitish clay, which is the poorest district out of the mountain region. Many districts have deep rich soils. The soil of the hilly country on the S. is dry and kind, but it is badly inclosed and destitute of shelter. Some of the best wheat and meadow lands in the S. of Ireland are situated in the level tract along the Suir. There are two districts almost wholly occupied by dairy farmers, the Walsh mountains and the southern part of the Castlecomer tract.

The manufacture of carpets, diapers, and tapestry was introduced into the county by the Countess of Ormond in 1359. James, duke of Ormond, about the middle of the seventeenth century, established and encouraged, at a great expense, both linen and woollen manufactures; and about the close of the same century the Bessborough family introduced the manufacture of linen into the southern parts of the county. These manufactures, which long flourished throughout the county, as well as that of blankets, introduced about a century ago, have now materially declined. A coarse frieze for home consumption is made among the peasantry. There are many flour-mills in the county, and the principal export is grain. There is also some trade in beer, whisky, and leather; but agriculture is the pursuit of the great body of the inhabitants. The chief crops are wheat, barley, bere, rye, oats, and potatoes, which ripen earlier than in most of the other Irish counties. Dairy and sheep farms are numerous; and the breeds of stock are chiefly native.

Two crossing lines of railway intersect this county, and the navigable rivers and the Grand Canal furnish facilities for transport to all parts of Ireland.

Divisions and Chief Towns.—The county contains ten baronies and 140 parishes, and is in the united diocese of Ossory, Ferns, and Leighlin. It is in the Leinster Circuit, and the assizes are held in the city of Kilkenny. It returns three members to Parliament, namely, two for the county and one for the city. It is in the Western Military District, and there are barrack stations at Kilkenny city and Castlecomer. The following are the principal towns, with the population of each in 1861:—*Ballyragget* is on the east bank of the Nore, about 10 miles N. by W. from Kilkenny. The ruins of the castle built here by the Butlers in the fifteenth century are extensive and interesting. Population, 985. *Callan* is on the N.E. bank of King's River, an affluent of the Nore, about 10 miles S.W. from Kilkenny. It is an ancient place, was formerly walled, and there are ruins of fortified castles and an abbey. Population of parish, 3986; of town, 2331. There are manufactures of flannels and shoes. This town is said to have been the ancient inheritance of the O'Callans. The modern parish church occupies a part of the old Augustinian minster. There are also a Roman Catholic chapel, a national school, a court-house, union workhouse, and a small barrack. *Castlecomer*, about 10 miles N.E. by N. from Kilkenny, is a well-built and clean little town, with a court-house, church, a Roman Catholic chapel,

schools, market-house, and fever hospital. About 2½ miles distant are extensive collieries. Population, 1435. *Freshford*, 8 miles N.W. by N. from Kilkenny, is a small town in a fertile tract of land, which extends from the Nore westward to the Bog of Allen at Urlingford. Population, 956. *Graig*, or *Graig-na-managh*, is beautifully situated on the west bank of the Barrow, about 15 miles S.E. from Kilkenny. There are some interesting ruins of an abbey, part of which have been converted into a Roman Catholic chapel. *Kilkenny* is the capital of the county. [KILKENNY.] *Thomastown* is situated on both banks of the Nore, 8½ miles S. by E. from Kilkenny, the larger portion occupying the left side. A handsome stone bridge crosses the river. The situation is beautiful, and well suited for trade, but it is, notwithstanding, a poor place. Population of the town, 1426; of the parish, 1932. It is a dis-franchised parliamentary borough; has several flour mills; and is a station on the Waterford and Kilkenny Railway.

History and Antiquities.—Kilkenny, as part of Leinster, belonged to the earl of Pembroke in the early part of the thirteenth century; but on the death of the earl in 1247 Kilkenny passed into the hands of various proprietors. Its early history is chiefly occupied with the feuds of the family of Ormond against the houses of Desmond or Kildare. The Graces also during this period were engaged in perpetual hostilities with the Fitzpatricks, Kavanaghs, and other Irish families. During the civil war against Charles I., Kilkenny was mostly held by opponents of the Crown.

Circular stone inclosures of the pagan era remain on the summits of the hills of Cloghmanta near Freshford, and Tory Hill, or Slieve Grian, near Kilmacow. The latter appears to have been a sepulchral cairn, inclosing a kistvaen, or stone chamber. The covering stone of the cromlech at Kilmogue is 45 feet in circumference, and is elevated at one end 15 feet from the ground. Another cromlech at Ballyheniberry has a covering stone 16 feet long, 10 feet broad, and 3 feet thick. There are numerous similar monuments of smaller dimensions throughout the county. The remains of raths and earthen tumuli are also of frequent occurrence. There are five round towers, one adjoining the cathedral church of St. Canice in Kilkenny, the others at Kilree, Tullocherrin, Fertagh, and Aghaviller. Of the monastic ruins, the most extensive and interesting are those of Jerpoint Abbey, on the Nore, 2 miles from Thomastown. The ruins occupy 3 acres, and are a fine specimen of the mixed Anglo-Norman and early English architecture. There are also monastic ruins at Graig and other places. The castles are very numerous, the chief one being Grandison Castle in Iverk, an ancient seat of the Butlers. It has three round towers towards the Suir, and two court-yards.

KILKENNY, a city and county of a city, the capital of the county of Kilkenny, 61 miles S. of Dublin, is finely situated on both sides of the Nore, the older and principal part occupying the western bank. It takes its name from the cathedral church (of St. Kenny or Canice) of the diocese of Ossory, founded here about the end of the twelfth century. The place was selected by the early Anglo-Norman invaders for the site of a castle. The present castle, built in 1195,

occupies a commanding site on the west bank of the Nore, and is the residence of the marquis of Ormond. The cathedral is seated on a gentle eminence on the same side of the river, at the opposite extremity of the city. The small river Bregah running into the Nore about midway between these points divides the city of Kilkenny Proper from Irishtown, or St. Canice, the former having originally been a dependency on the castle, the latter on the cathedral. The large suburb on the opposite side of the river, called Englishtown, is connected with Kilkenny Proper and Irishtown by two handsome bridges. Englishtown still retains its name, but Irishtown has merged into the city of Kilkenny.

The chief object of antiquity is the cathedral church of St. Canice. It is a cruciform building, surmounted by a low tower: extends from E. to W. 226 feet, and from N. to S. 123 feet. The chapel of St. Mary in the north transept serves as the parish church. The oldest parts of the edifice appear to be of the architecture of the early part of the thirteenth century. Of the original castle there remain three massive towers worked into large additions in the French taste of the seventeenth century, made by James, duke of Ormond, in 1682. The building occupies three sides of a quadrangle, having a garden and fountain in front and a lofty terrace towards the Nore. The abbey church of St. John's has been converted into a parish church. Black Abbey has been partly restored, and converted into a church for Roman Catholics. The body and tower of the Franciscan friary are still standing.

The town is well built, and has a busy and cheerful appearance, particularly that portion of it constituting Kilkenny Proper. It is the largest town in Ireland wholly inland. The building material is usually stone whitened or dashed with rough-cast. Kilkenny contains a county court-house, county prison, city prison, barracks, infirmary, fever hospital, union workhouse, cathedral, bishop's palace, chapter-house, deanery, a round tower, two parish churches, seven Roman Catholic chapels, one of which (the cathedral) has been recently built, two monasteries, a convent, Presbyterian and Methodist meeting-houses, an endowed grammar-school called the College of Kilkenny, a Roman Catholic college, national schools, a lunatic asylum, almshouses, &c. At the college Swift, Congreve, and Bishop Berkeley were educated.

The coarse linen and woollen manufacture, although much decayed, is still carried on. But the corn, provision, and general retail trade now form the principal business.

There are several distilleries, breweries, tanneries, and flour mills in the town and its vicinity. Coal and marble are raised in the neighbourhood; the former is sulphureous, and burns without smoke or flame; the latter, which is black, is much used for chimney-pieces and ornamental purposes. The streets of the town are also paved with it.

The city of Kilkenny returns one member to Parliament. The county of the city comprises an area of 26½ square miles, or 17,012 acres. The population in 1851 was 15,808; in 1861, 14,174, including 12,769 Roman Catholics. The number of voters in the city in 1869 was 739.

There were formerly two municipal corporations; one for the English, and the other for the Irish town,

but by the provisions of the Municipal Reform Act they are amalgamated, and divided into two wards, each having three aldermen and nine councillors. The assizes for the county are held in the new court-house, and quarter, as well as petty sessions, are held in the town. The mayor presides over a weekly Court of Conscience, in which debts amounting to 2*l*. (Irish currency) may be recovered.

Kilkenny is connected by railway with Dublin and Waterford.

KILLALA, an Irish bishopric in the archiepiscopal province of Armagh, is now united with Tuam and Achonry, thus forming the united bishopric of Tuam, Killala, and Achonry. The town of Killala is a small seaport in the county of Mayo, on an extensive inlet of the Atlantic bearing the same name. The population is 942. The place has a small cathedral, a round tower, and a harbour. In 1798, a French force landed at Killala Bay, and took the town.

KILLALOE. [CLARE.]

KILLARNEY. [KERRY.]

KILLARNEY, Lakes of. [KERRY.]

KILLENITE, a mineral of a green-brownish colour, so called from occurring in the granite veins of Killeny, near Dublin. It occurs both massive and crystallized; but the crystals are not perfect. Its specific gravity is 2·69; and its constituents, according to Dr. Thompson, are—silica, 49·08; alumina, 30·60; potash, 6·72; oxide of iron, 2·27; water, 10·0.

KILLIECRANKIE, BATTLE OF, was fought July 27, 1689, by the troops of William and Mary, against the forces which were held together in Scotland by Viscount Dundee, in the interest of James II. The two armies confronted each other at the Pass of Killiecrankie, in Perthshire. The royal army, commanded by General Mackay, numbered 4000; that of Dundee only 2500 foot, with a small troop of horse. The contest was decided in a few minutes; the Highlanders rushed on with their swords, and instantly scattered the enemy. Mackay lost 2000 men; Dundee, 900. The latter fell by the shot of a bullet in the moment of victory; and shortly afterwards Scotland peacefully submitted to the Revolution Settlement. Professor Aytoun has made this battle the subject of a fine historical poem, entitled 'Killiecrankie,' and its incidents are described with characteristic eloquence by Macaulay in his History.

KILMARNOCK. [AYRSHIRE.]

KILOGRAMME, a French measure of weight of 1000 grammes, equal to 2·2046 lbs. avoirdupois; 100 kilogrammes being equal to 1·9684 cwt. To convert pounds avoirdupois into kilogrammes, or the reverse, divide or multiply by 2·20464. The kilogramme is equal to 15432·48 grains Troy. [GRAMME.]

KILOMETRE, the French itinerary measure, or mille, being the tenth part of the new league, containing 1000 metres, or 1093·6389 yards.

KILKENNY. [FIFESHIRE.]

KILRUSH. [CLARE.]

KILT, a loose dress falling from the waist to the knee in the guise of a short petticoat. It is worn in the Scottish Highlands by men, but the fashion is said to have been introduced by an English tailor.

The tunic is undoubtedly Celtic. After having been considered for many years a national dress, it is now rapidly hastening into disuse, though retained by a few Highland regiments.

KILWINNING. [AYRSHIRE.]

KIMBOLTON. [HUNTINGDONSHIRE.]

KIMERIDGE CLAY, in Geology, one of the strata of the Upper Oolitic group. It is named from Kimeridge, Dorsetshire, where it is typically developed. It occurs also in the vale of Aylesbury, Buckinghamshire, where it is highly fossiliferous. Kimeridge coal is a remarkably bituminous shale found in the Kimeridge clay beds, of little use.

KIN. [CONSANGUINITY; DESCENT.]

KINCARDINESHIRE, or the *Mearns*, as it is commonly called, is a maritime county of Scotland, situated between $56^{\circ} 43'$ and $57^{\circ} 5' N.$ lat., and between $1^{\circ} 47'$ and $2^{\circ} 30' W.$ long. It is bounded N. and N.W. by Aberdeenshire, S. and S.W. by Forfarshire, and E. by the North Sea. Its greatest length N. to S. is 35 miles; its greatest breadth E. to W. is 24 miles. The area is 394 square miles, or 252,250 acres. In 1861 the population was 34,466—16,744 males, and 17,722 females. There were 6697 inhabited houses, 254 uninhabited, and 45 building. In 1861 the inhabitants numbered 34,598. The registered county constituency in 1869 was 1680, who return one member to the House of Commons; while Bervie contributes to Montrose.

The Grampian hills occupy the western and central parts of Kincardineshire. Mount Battock, the highest summit, rises 2611 feet above the sea; Clach-na-Bayne is 1906 feet. This elevated and sterile region comprises about one-third of the county. The rest, to the extent of more than 100,000 acres, is well cultivated, and the soil fertile throughout. In the S. and E. lies the rich, low, arable tract called the How of the Mearns, comprising about 50,000 acres, on a basis of old red sandstone. The climate is mild. The estates in the county are generally large; the farms of all sizes, some from 400 to 500 acres, and the best generally let on lease for about nineteen years. Great improvements have been made recently in agriculture. The chief crops are oats, grain, barley, turnips, potatoes, flax, and wheat.

Cattle, chiefly of the short-horned breed, are fed on most farms; and the mountains yield extensive pasture for sheep. The shores of Kincardineshire abound in fish, and are one of the principal resorts of the herring, many thousand barrels of which are cured annually, but the nature of the coast, and the want of harbours sufficiently capacious prevent the full development of this trade.

The mineralogy of this county is not of great importance. In many places there are limestone quarries; and as the stone is of excellent quality, a more abundant supply of fuel is all that is wanted to render them of great value. There are also granite sandstone quarries.

The principal rivers are the Dee on the N., and the North Esk on the S. [ABERDEENSHIRE; FORFARSHIRE.] The other streams, the Dye, Cowie, Carron, Bervie, and Luther are small, but some of them contain good salmon fisheries. The weaving of dowlais, household and coarse linen, &c., is the chief manufacture. A large number of wooden snuff-boxes are also made.

The county does not contain any towns of importance. The following are the principal places, with the population of each in 1861:—

Bervie, or *Inverbervie*, is situated on the coast, about 9 miles S. by W. from Stonehaven, 13 from Montrose by road, and 8 from the Laurencekirk station of the Scottish North-Eastern Railway. The Water of Bervie, a small river, falls into the sea a little below the town, and forms a harbour for fishing boats at the village of Gourdon. A handsome bridge crosses the river. There is a church and a townhouse. Population of the parish, 1561; of the parliamentary and royal burgh, 952, mostly engaged in fishing. There are also some linen manufactures and a trade in corn. The charter of royal burgh was granted by David II., in 1362; and it is now governed by a provost, two bailies, and fifteen councillors. The parliamentary and municipal electors number only 32. Bervie is included in the Montrose parliamentary district, which returns one member.

Johnshaven is a village on the coast, with a small harbour, about 4 miles S. by W. from Bervie. Population, 1088.

Laurencekirk, a village about 6 miles W. from Bervie, contains a parish church and an Episcopalian chapel. A little linen-weaving is carried on, and a great many wooden snuff-boxes of peculiar workmanship are made here. Population, 2110.

Stonehaven, a borough of barony, consists of a new and an old town, connected by a bridge across the Carron. In summer it is visited for sea bathing. The harbour admits only small vessels. There are haddock and herring fisheries, manufactures of cottons and linens, a distillery and a brewery, and some mills for spinning woollen yarn; and the town is also the seat of sheriff courts. The place is included in the parishes of Dunnottar and Fetteresso, and adjacent to it are the two parish churches, and the fishing village of Cowie. About 2 miles south, on a rock projecting into the sea, are the remains of Dunnottar Castle, the former residence of the Earls Marischal, feudal superiors of Stonehaven. The population of the town in 1861 was 3009. It is connected by railway with Aberdeen (15 miles N.E.).

Kincardineshire includes nineteen parishes, and parts of three others; and two presbyteries in the synods of Aberdeen and Angus and Mearns. This county was part of the Roman province of *Vespasiana*; and Roman stations are traced at Raedykes and Fordoun. There are also old castles at Dunnottar, Kame of Mathers, and Fordoun.

KING, a person in whom are vested the highest executive functions in a sovereign state, with a share, more or less limited, of the sovereign power.

It is immaterial whether the power of such a person is limited only by his own will, or immemorial usage and written laws, or in any other way; still such a person is a king. Nor does it signify whether he succeed to the kingly power by descent and inheritance on the death of his predecessor, or is elected by some council or limited body of persons, or by the suffrages of the nation. The kings of Poland were elected; the king of England succeeds by hereditary right.

The distinction between a king and an emperor is not one of power, but it has an historical meaning. [EMPEROR.]

The origin of the word *king* is disputed. It seems derived from, or connected with, the Latin *gens* and the Greek *genos*, and is identical in meaning with the Greek *basileus* and the Latin *rex*. It comes to us from the old Teutonic *kon-ung*, or *cyn-ing*; that is, the cunning, or able man, the man able to rule.

There are other words employed to designate the person who is invested with the chief power of particular states, in using which we adopt the word which the people of those states use, instead of the word *king*. Thus there is the *Shah* of Persia, the grand *Sultan*, and formerly there was the *Dey* of Algiers. In the United States of America certain powers are given by the federal constitution to one person, who is elected to enjoy them for four years with the title of *President*. A *Regent* is a person appointed to exercise the kingly office during the minority or the mental incapacity of the real king: this definition at least is true of a regent of the British empire. Nothing can be more various than the constitutional checks in different states on the kingly power, or, as it is more usually called in England, the royal *prerogative*.

The English kingly power is traced to the establishment of Egbert, at the close of the eighth century, as king of the English. The accession of William, duke of Normandy, after the battle of Hastings, in 1066, is generally regarded as a new beginning of the race of English kings, for William was but remotely allied to the Saxon kings. In his descendants the kingly office has ever since continued; but though the English throne is now hereditary, there has not always been regular hereditary succession; it has been often disturbed. The last disturbance was the succession of William III., after the abdication of James II., when an act was passed excluding the male issue of James, the issue of his sister the duchess of Orleans, and the issue of his aunt the queen of Bohemia, with the exception of her youngest daughter the Princess Sophia, and her issue, who were Protestants. On the death of Queen Anne this law of succession took effect in favour of King George I., son of the Princess Sophia.

The heir now succeeds to the throne immediately on the decease of his predecessor. The course of descent is to the sons and their issue, according to seniority; and if there is failure of male issue, the crown descends to a female. The person who succeeds by descent to the crown of England succeeds also to the kingly office in Scotland and Ireland, and in all the possessions of the British empire.

At his coronation the king makes oath to three things:—that he will govern according to law; that he will cause justice to be administered; and that he will maintain the Protestant Church. [CORONATION.]

His person is sacred; and he is not personally responsible for any of his acts. His concurrence is necessary to every legislative enactment. He sends embassies, makes treaties, and enters into wars, without any previous consultation with Parliament. He nominates the judges and the other high officers of state, the officers of the army and navy, the governors of colonies and dependencies, the bishops, deans, and some other dignitaries of the Church. He calls Parliament together, and can at his pleasure prorogue or dissolve it. All hereditary titles are

derived from his grant. He can also grant privileges of an inferior kind, such as markets and fairs.

But the exercise of any or all of these powers is practically limited. The king cannot act politically without agents, and these agents may be brought to account for his acts if he transgress the law. The agents by whom the king acts are his ministers, whom he selects and dismisses at his pleasure; but practically he cannot keep a ministry which does not command a majority in the House of Commons; and, virtually, all the powers of the Crown are exercised by the chief minister, or prime minister for the time. [CABINET.] The king now does not even attend the cabinet councils; and the power which in theory belongs to his kingly office, and in fact in earlier periods was exercised by him, is almost formal. But though the king of England has lost his real power, he has perfect security for his person, and for the transmission to his descendants of all the honour and respect due to the head of the most extensive empire on the globe. He also possesses considerable personal influence, and retains a direct control over the military force.

KING-AT-ARMS, an officer of great antiquity, who presides over the chapters and directs the proceedings of heralds. At present his chief duty is to regulate the armorial bearings of gentlemen and the order of state ceremonials. In England there are three kings-at-arms—Garter, principal; Clarenceux, and Norroy, provincial; so called because their duties are limited to the provinces. The name *Clarenceux* is derived from the duke of Clarence, Henry V.'s brother, first king-at-arms for the south of England; that of *Norroy* is Norman-French for *northern king*. There are also a Lyon king-at-arms for Scotland, and an Ulster king-at-arms for Ireland. [HERALD.]

KING, PETER, LORD, was born in 1669, at Exeter, where his father was a tradesman. His mother was a sister of John Locke, by whose advice it is said Peter was sent to study at the University of Leyden. In 1691 he published the first part of his 'Inquiry into the Constitution, Discipline, Unity, and Worship of the Primitive Church,' which displayed considerable learning, attracted much attention, and caused some controversy. Meanwhile King had entered himself at the Inner Temple, and was in due course called to the bar. In July, 1708, he was chosen recorder of London, and was soon after knighted. In 1709 he was appointed by the House of Commons one of the managers in the impeachment of Dr. Sacheverell; and in 1712 he gave his services, without a fee, as one of the counsel for Mr. Whiston, on his trial for heresy before the Court of Delegates. In November, 1714, a few months after the accession of George I., Sir Peter King was made Chief Justice of the Common Pleas, and in June, 1725, was appointed Lord Chancellor, and raised to the peerage as Baron King, of Ockham in Surrey. He resigned the seals on November 26, 1733, and died at his seat near Ockham in Surrey, on July 22, 1734.

KINGFISHERS (*Halcyonidae*), a family of the *syndactyle* group of *Passeræaux*, according to Cuvier; and according to Mr. Vigors, of the *Fissirostral* tribe of his order *Insesores*. [INSESORES.] For other modes of arrangement see Linnæus, Latham, Lacépède, Duméril, Meyer, Illiger, Vieillot, De Blainville, &c. Consult also Mr. Vigors 'On the Natural

Affinities that connect the Orders and Families of Birds; the Prince of Musignano, in his 'Tabella Analitica de'Generi' ('Specchio Comparativo,' 1827); and Eyton's 'History of the Rarer Species of British Birds;' also Selby, Gould, Yarrell, &c. Swainson's 'Classification of Birds' may be referred to with advantage; and Rymer Jones' 'Structure of the Animal Kingdom.'

The *Halcyonidae* are universally distributed, being found alike in the Old and New World, in Australia, and the islands of the Southern Ocean. The genera included under this family title are very numerous, and the species differ considerably from each other in habits. Most are piscivorous, darting upon their finny prey when it approaches near the surface of the water. Others, however, as the puff-birds (*Tamatia*), are insectivorous; and others, as the Gigantic or Great Brown Kingfisher of New Holland (*Dacelo gigantea*), or Laughing Jackass, feed upon large insects, reptiles, and even small quadrupeds, being unfitted, from the character of their plumage, for plunging into water.

When we say that the Kingfishers are *syndactyle*, we mean that the external toe before is united for

Gigantic Kingfisher (*Dacelo gigantea*).

the greater part of its length to the middle toe, as in the Bee-eaters (*Merops*) and others.

Mr. Swainson, in his 'Classification of Birds,' when treating of the *syndactyle* foot, allows the term to be good, if limited to such feet, with united toes, as are of a different formation to all others, and would not, even if the toes were free, come under any of the definitions which he had previously given. Such a form of foot, he says, will be found in the genera *Merops* and *Alcedo*, containing the Bee-eaters and Kingfishers, to whose feet he especially limits the term *syndactyle*. 'The habits of these two groups,' continues Mr. Swainson, 'as far as concerns the use of their feet, are nearly the same, for in neither are these members ever employed but to rest the body. The Kingfisher watches patiently from a fixed station, generally a naked twig overhanging the water, for such fish as come within its reach, and then, after

a time, flies to another station, where it alights and remains. The feet, from not being used for walking or standing, are consequently very small, and the toes imperfectly developed; there are three toes in front and one behind, but two of the former might be almost reckoned as only one, since they are united together even to the commencement of their respective claws, and the inner toe is not half the length of the others, and seems to be rudimentary: it has a claw, and is rather more detached at its tip than the other two; in some, as in the Three-toed Kingfishers, this inner toe disappears. The hinder toe is very short, and scarcely longer than the inner one. The scales of the whole foot are so thin and transparent that they can scarcely be seen in the small species by the naked eye. Those who have seen so much of the true Kingfishers, know that they never perch upon any other than small or slender branches; and this we may infer from the shape of the foot. The two outer anterior toes are very long, so that they would completely clasp two-thirds of the circumference of a small branch, the other third being embraced by the hinder toe. This fact is further confirmed by the unusual flatness of the soles of all, and by the acuteness of the claws, which, from being but slightly curved, would not upon a small branch come into contact with the wood. The union of the three anterior toes, by producing considerable breadth of sole, gives an unusual degree of steadiness to the bird, highly conducive to its remaining very long in one position.'

The following characters are assigned the *Halcyonidae*:—Wings rounded, not formed for rapid flight; feet very feeble; toes in pairs.

The whole of the genera are sedentary, watching for their food from a fixed station, which they only

Common Kingfisher (*Alcedo ispida*).

quit as soon as their prey approaches sufficiently near to come within the sweep of their wings; if unsuccessful in their first attack, they do not pursue their game, but return again to their post, and patiently wait for another luckless straggler; if their first attack is successful, they return with their victim to the same station, and then proceed to swallow it. Of the *Halcyonidae* one species only is British, viz., the Common Kingfisher (*Alcedo ispida*), so remarkable for the brilliancy of its plumage. This is the *Martin Pêcheur* of the French; *Uccello della Madonna*, *Uccello Santa Maria*, *Piombino*, and *Alcione*, of the Italians; and *Gemeine Eisvogel*, of the Ger-

mans. The habits of this species are described by Pennant, Montagu, Selby, Gould, Yarrell, and others.

KINGHORN. [FIFESHIRE.]

KINGROAD, at the mouth of the river Avon, in the Bristol Channel, is between the counties of Gloucester and Somerset. Vessels too large to proceed up the Avon to Bristol lie at anchor here.

KING-WOOD, a beautiful violet-tinted wood of Brazil, imported into this country in trimmed logs, from two to seven inches in diameter. It is principally used in turning and cabinet work.

KINGS, the *Books of*, the name of two books of the Old Testament. They originally formed only one book in the Hebrew text. In the Septuagint they are divided into two books, and are entitled 'the third and fourth books of reigns' or kingdoms, since the first and second books of Samuel are called in this translation the first and second books of Kings. These books, in common with the books of Chronicles, and many others of the Old Testament, are generally ascribed to Ezra.

KING'S BENCH. [COURTS.]

KINGSBRIDGE. [DEVONSHIRE.]

KINGSCLERE. [HAMPSHIRE.]

KING'S COLLEGE, CAMBRIDGE, was founded by King Henry VI. in 1443, in conjunction with Eton College, whence all the scholars were formerly supplied by a regular succession. Under the new statutes, which came into operation in 1861, the foundation will in future consist of a provost, at least forty-six fellows, and at least forty-eight scholars. The fellows will be elected from among all members of the college who are of sufficient standing.

Twenty-four scholarships will be appropriated to the scholars of Eton College, and the remaining twenty-four will be open. They will all be tenable till the holder is of M.A. standing, or fellow of this or any other college. The number of twenty-four Eton scholarships must be completed before any open scholarships are established.

The society of Eton consists of a provost, seven fellows, and seventy scholars. The election to the Eton scholarships is held at Eton about the end of July or beginning of August, at which time a general examination as to proficiency in divinity, classics, and mathematics takes place before the provost of each college, the vice-provost and head master of Eton, and two *posers* or examiners nominated by King's. Only such a number of candidates will be elected upon each occasion as will fill the actual number of scholarships then vacant.

Some peculiar privileges appertain to King's. The provost has absolute authority within the precincts; and by special composition between this society and the university, its undergraduates are exempt from the power of the proctors and other university officers within the limits of the college.

The original buildings of King's College consisted of the present chapel and a quadrangular court to the north of it. The buildings which constituted this court having become much decayed, it was determined that a large quadrangle should be erected to the south of the chapel. Gibbs was appointed the architect. The building was commenced in 1724, and he erected on the west side of the quadrangle the Fellows' building, or Grecian building, as it is commonly called. Nothing more was done till 1824,

when the new buildings were recommenced by Wilkins, and completed in 1828.

The quadrangle is 280 feet in length by 270 feet in breadth, and consists of the hall, library, chapel, and apartments for the fellows and scholars. The Grecian building, hall, and library, are handsome structures; but the architectural boast of King's College is the chapel, the only part of the original buildings which now remains. The first stone was laid in September, 1447. In 1508 Henry VII. gave 5000*l.* towards the completion of the building, and his executors, in 1513, under a power conferred by his will, gave a further sum of 5000*l.* for the same purpose. In July, 1515, the exterior, including the roofs, was completed. In 1526 an agreement was made for the painted windows. The screen and stalls were not finished till about 1534.

The interior of this magnificent chapel is 291 feet long, 45½ feet wide, and 78 feet high. Its exterior appearance, with its towers and buttresses, lofty windows, pinnacles, and pierced battlements, is as beautiful as it is grand and imposing. In the interior the vast stone roof, unsupported by pillars, is one of the wonders of architectural skill. Eleven principal ribs spring from the buttresses on each side, forming an arch somewhat flattened at the centre, whence ponderous stones, each of which is said to weigh a ton, hang as pendants. The principal ribs are connected with each other by diagonal ribs, and the whole roof is formed into one great whole of the lightest and most richly carved fan-tracery. The great east window and twenty-four side windows, each nearly 50 feet high, are filled with painted glass, and form a series of scriptural pictures of exceeding beauty. The great west window alone is of plain glass, probably for the sake of additional light. (*Cambridge University Calendar*, 1869.)

KING'S COLLEGE, LONDON, occupies the east wing of Somerset House. It was founded in 1828 on the fundamental principle, 'that instruction in the Christian religion ought to form an indispensable part of every system of general education for the youth of a Christian community.' The college is only intended for Church of England students. The studies embrace theology, literature, science, and medicine. A limited number of matriculated students reside within the walls. There are also evening classes and a school for young men in connection with the college. The museum contains George III.'s collection of mechanical models and philosophical instruments, presented by the queen; and also the calculating machine invented by Mr. Babbage.

KING'S COUNTY, an inland county of the province of Leinster, in Ireland, is bounded N. by West Meath, E. by Kildare, S. by Queen's County and the county of Tipperary, and W. by the river Shannon, which separates it from Galway and Roscommon. The greatest length E. to W. is 45 miles; the greatest breadth N. to S. is 39 miles. The area is 772 square miles, or 493,985 acres, of which 337,256 are arable, 145,836 uncultivated, 8258 in plantations, 902 in towns, and 1733 under water. The population in 1851 was 112,080; in 1861, 90,043, of whom 79,955 were Roman Catholics, and 9109 belonged to the Established Church.

Surface.—A series of low limestone hills, running in a north-easterly direction, divides the northern por-

tion of the county into two districts of unequal area, of which the one discharges its waters eastward to the Barrow; and the other, which is of about double the extent of the former, westward into the Shannon. This range of eminences terminates in the north-eastern part of the county in the conical hill of Croghan, from which the Yellow River flows northward into the Boyne. The northernmost part of the county is well cultivated; but this is succeeded on the south by peat bog, forming a portion of the great Bog of Allen. This tract, extending about 12 miles every way, is divided into two principal valleys by the Philipstown and Cushina rivers, which flow into the Barrow. The highest part of the bog is 286 feet above the level of the sea. There are numerous other bogs in this county. The valley of the Barrow, which consists on the King's County side of an arable margin interposed between it and the Bog of Portarlinton, is highly cultivated, and to a considerable extent occupied by the demesnes of the resident gentry. The district westward of the range of hills is watered by several small tributaries of the Shannon, among which are the Brosna, Clodagh, Frankford, and Blackwater. In this district, as in the eastern, the bogs are very numerous. The bogs on the western side of Tullamore, lying along the southern side of the Grand Canal, occupy an area of 11,588 acres. They are disposed in three principal tracts, separated from one another by low hills of limestone gravel, and bounded on the south by the hill of Cloghan, which separates the bogs immediately bordering on the canal from the more extensive tract lying between its southern declivity and the range of Slieve Bloom. This latter tract, consisting of five principal fields, extends over 23,986 acres. The valley of the Brosna is the best cultivated portion of the north-western division of the county. The river winds between undulating banks, which form a margin of considerable breadth on each side, free from bog, and towards West Meath spread into a well-cultivated open country. The district included between the Brosna and the county of West Meath, with the exception of the arable margin of the river, is almost wholly occupied by bogs. One of the bogs of this district is that of Kilmaleady, now generally known as the 'moving bog,' which in the year 1821 burst its bounds and overflowed nearly a mile and a half down an adjoining valley.

The remaining portion of the county, included between the Slieve Bloom mountains, Tipperary, and the Shannon, has a general slope towards the Little Brosna, which forms the boundary between King's County and Tipperary. The portion which descends immediately to the Shannon is bleak moorland, comprising a considerable part of the bogs lying south of Cloghan Hill; but the banks of the Shannon are richly clothed with meadows, though liable to frequent floods. The valley of the Little Brosna is an undulating district, containing extensive tracts of pasture, and towards the mountains abounding with varied and pleasing scenery. The highest elevation of the Slieve Bloom mountains is 1689 feet. They extend 15 miles in a line from north-east to south-west. The navigation of the Shannon is aided by three lateral cuts or canals, at Meelick, Banagher, and Shannon Bridge. Many steamboats ply on this part of the Shannon.

Climate.—Notwithstanding the great extent of wet ground on the surface of King's County, the climate is neither damp nor unwholesome; it is, indeed, drier than in most Irish counties. This is partly accounted for by the antiseptic quality of the peat bog, and partly by the fact of the county lying comparatively high and open.

Geology.—The floetz limestone of the central plain spreads over the entire area of the county, with the exception of the portions occupied by the protruded masses of the Slieve Bloom chain and the hill of Croghan. The range of Slieve Bloom consists of a nucleus of clay-slate, supporting flanks of sandstone. Croghan Hill consists of a protruded mass of trap conglomerate, rising about 500 feet above the level of the surrounding country, with steep declivities towards the south. The hill is almost all under cultivation, and yields the most abundant white and green crops without any manure whatever. Massy strata of greenstone appear also between Croghan Hill and Philipstown. Granular limestone occurs at the Seven Churches in the north-west of the county, and has been quarried to the extent of 3000 cubic feet of good gray marble. Banks of rolled limestone gravel, called eskers, occur frequently throughout the floetz limestone district. The bogs, which occupy so large a portion of the county, generally repose on limestone gravel.

Products, &c.—The soil in general is of average fertility, and can be made to yield very good crops in the arable districts by manuring with the lime and bog-stuff which abound throughout the county. The banks of the Shannon, where they are occasionally overflowed, afford considerable tracts of fine pasture. The chief grazing districts in the county lie on the borders of West Meath, where the land is considered very favourable to wool-growing. The principal crops are wheat, barley, oats, and potatoes.

The linen manufacture is carried on to a small extent; and there is a little weaving of friezes, stuffs, and serges. Distilling, brewing, and corn-grinding occupy a few hands. The occupations of the inhabitants, however, are chiefly agricultural; the manufactures being only for home consumption.

Communications.—The Grand Canal traverses the county from Edenderry in the east, to Shannon Harbour in the west. The Athlone extension of the Great Southern and Western Railway runs through it from north-west to south-east, passing through Portarlinton, Tullamore, and Clara; and in the south there is a branch of the same railway from Roscrea to Parsonstown.

King's County is divided into twelve baronies and fifty-one parishes. It is chiefly in the dioceses of Meath, Killaloe, and Kildare, but portions are in Ossory and Clonfert. It is in the Home Circuit, and the assizes are held at Tullamore. It returns two members to Parliament. The number of voters on the county register in 1869 was 3435. There are no parliamentary boroughs. The county is within the Dublin or Northern Military District; and there are barrack stations at Parsonstown, Banagher, Philipstown, Shannonbridge, and Tullamore. The principal towns, with the population of each in 1861, are the following:—*Banagher* is 82 miles W. by S. from Dublin, on the east bank of the Shannon, at one of the guarded bridges across the Shannon to

Connaught. The town consists principally of one very long street, occupying elevated ground. It has a considerable trade in the export of corn and other provisions. There is a spacious church and a Roman Catholic chapel. Population, 1426. *Edenderry* is 32½ miles W. from Dublin. The Grand Canal passes within a mile of the town, to which a branch has been extended. It contains a town-hall and a church, and is a neat and clean place. Population, 1661. *Parsonstown*, formerly and still generally called *Birr*, is 69 miles W.S.W. from Dublin. The town is situated on a gentle acclivity on the north bank of the Little Brosna. The modern parts are laid out in good streets and squares, and respectably inhabited. The church and the Roman Catholic chapel are handsome edifices. The surrounding country is fertile and flourishing, and the town has an extensive retail trade. Population, in the town, 5401; in the parish, 9292. At *Birr Castle*, which has been rebuilt, is the earl of Rosse's very powerful telescope, which has so largely aided the researches of modern astronomers. *Portarlinton* is situated on both sides of the Barrow, the largest portion being in Queen's County. [*QUEEN'S COUNTY.*] *Tullamore*, the assize town of the county, is situated near the centre of that vast mass of peat-moss called the Bog of Allen, 50 miles W. by S. from Dublin. The Grand Canal passes it on the north side, and the stream called the Tullamore River flows through it. Regularly built, and with wide streets, it is a respectable-looking town. The court-house, gaol, church, Roman Catholic chapel, and public schools, are conspicuous and rather handsome buildings. There is daily communication with Dublin, by means of swift iron boats, and the canal boats to and from Ballinasloe and Limerick all call here. Tullamore, has risen since 1790 from a small village, and is now the principal shipping station on the Grand Canal, by means of which great quantities of corn and other provisions are forwarded to Dublin. There is a large distillery and brewery, together with several other branches of trade, connected with the supply of a large town and populous district. There are barracks, market-house, union workhouse, meeting-houses for Dissenters, &c. The environs are well cultivated, and contain several neat cottages and villas. Population, 4797.

History.—Although not reduced to shire-ground as one county until the time of Mary, King's County was partially included in other shires at a very early period. In 1557 the Act was passed which erected the whole into one county under its present name. Before that period it was generally designated Western Glenmalery, to distinguish it from Eastern Glenmalery, the present Queen's County. The native chieftains for a length of time struggled against the new settlement, until 1600, when the Lord Deputy Mountjoy and Sir Oliver Lambert succeeded, after a deplorable destruction of life and property, in finally reducing them. King's County, like others, was involved in the rebellion of 1641; and extensive confiscations followed.

The ruins of the seven churches of Clonmacnoise, in the north-western part of this county, form one of the most interesting groups of ecclesiastical remains to be met with in Ireland. The buildings are of various dates, from, probably, the seventh century

to the twelfth. Surrounding the Abbey of St. Kieran of Clonard is the ancient burying-ground, containing about two Irish acres, and occupied with the sites and ruins of various religious houses. The whole is inclosed with a wall, at two of whose angles ancient round towers are placed. The buildings within the precincts are chiefly chapels, erected over family burying-places by the various Irish kings and chieftains. There are the remains of several other religious houses in the immediate vicinity. The entire group occupies a gently swelling bank rising from the Shannon about midway between Shannon harbour and Athlone. Many other religious houses are enumerated, besides numerous remains of feudal castles, chiefly of the Elizabethan era, of which those of Cloghan, Leap, and Birr are still inhabited.

KINGSCOURT. [*CAVAN.*]

KING'S EVIL, a scrofular affection of the glands. It was long believed by the superstitious that the touch of the sovereign was an immediate cure for this disease, but no sovereign has 'touched' for the 'evil' since Queen Anne.

KING'S LETTER. [*BRIEF.*]

KING'S LYNN. [*NORFOLK.*]

KINGSTON, a city of Western Canada, on the site of Fort Frontenac, in the north-east extremity of Lake Ontario, at the mouth of the Cataract, and at the terminus of a branch of the Grand Trunk Railway, 165 miles E.N.E. of Toronto. Its population in 1861 was 13,743. It was the seat of government in Canada from 1840 to 1845; and next to Quebec and Halifax it is the most important military station in British America.

The city covers a large surface, and has many elegant buildings, large shipbuilding yards, iron foundries, and manufactures of steam engines and agricultural implements. It is the chief seat of the trade between Upper and Lower Canada, and the harbour—which is sheltered by Wolfe and Garden Islands—has a long row of wharves, with machinery capable of unloading 3000 bushels of grain per hour; there is also an extensive trade with steamers on the Lake, the St. Lawrence, and the Rideau Canal.

In 1862 Kingston became the seat of the new colonial bishopric of Ontario. In the city are the Queen's University and College, incorporated in 1841, which has faculties of theology, law, and medicine, seventeen professors and lecturers, and an average of about 150 students; Regiopolis college, a Roman Catholic institution; a county grammar-school, and many private educational establishments, and the provincial penitentiary.

KINGSTON. [*JAMAICA.*]

KINGSTON-ON-HULL. [*HULL.*]

KINGSTON-ON-THAMES. [*SURREY.*]

KINGSTOWN. [*DUBLIN.*]

KING'S TRADESMEN, in Scotland, are tradesmen holding commissions under the Privy Seal, in right of which they are not liable for assessment for the poor or other burghal prestations. The right of the sovereign to appoint such persons is limited to one of each craft or occupation.

KING-TE-CHING, a town of China, in the province of Kiang-si, 110 miles N.E. of Nan-tchang. It is the principal seat of the manufacture of porcelain in China, for which it is said 500 furnaces are employed. The population is estimated at 1,000,000.

KINGTON. [HEREFORDSHIRE.]

KINIC ACID, sometimes called Cinchonic Acid, is obtained from cinchona bark. It has a very sour taste; it reddens litmus paper strongly, is unalterable in the air, dissolves in $2\frac{1}{2}$ times its weight of water at 48° , and is also soluble in alcohol. The crystals contain one equivalent of water. The acid is composed of oxygen⁹, hydrogen⁹, and carbon¹⁵.

Kinic acid combines with other substances to form *Kinates*. Among them the following are the most important:—*Kinate of Quinia* is very bitter, readily soluble in water, and but slightly in alcohol of sp. gr. 0.837. It is decomposable by heat, without residue. By evaporation the solution is reduced to a viscid paste, which when moistened and exposed to the air exhibits rudiments of crystallization. It is composed of kinic acid¹, quina². *Kinate of Cinchona*, composed of kinic acid¹, cinchona², is bitter, very soluble in water, and slightly in alcohol. *Kinate of Lime* (kinic acid¹, lime¹, water¹⁰), crystallizes in rhomboids and hexagonal plates; it has little taste; it is soluble in water.

Kinic acid may be artificially combined with most of the metals, and thus forms *Kinate of Potash*, *Kinate of Soda*, *Kinate of Zinc*, *Perkinate of Iron*, *Kinate of Lead*, *Kinate of Copper*, *Perkinate of Mercury*, *Kinate of Silver*.

KINKAJOU (*Cercoleptes caudivolvulus*), a plantigrade animal which is usually classed with the true bears (*Ursidae*), though it differs considerably from them in its general characters. It has short and blunt canine teeth, behind which are two small pointed pre-molars, and behind these three tuberculated molars. The plantigrade feet have five toes, which are more widely separated than in the bears, and can be used more freely. The kinkajou is about the size of a domestic cat, and is covered with yellowish woolly fur. It feeds on different kinds of fruit and honey, is a native of the tropical countries of America, and is of an extremely gentle and playful disposition in captivity. It is therefore much esteemed as a domestic pet. Its agility is remarkable, and it speeds from tree to tree like the flying monkey. (Bates, *The Naturalist on the River Amazons*.)

KINO, an astringent substance, the concrete juice of several plants. The different extracts differ in their chemical habitudes with re-agents, but all agree in possessing a strong astringent power. Kino most commonly occurs in grains of a shining aspect and rich ruby red colour; they are easily reduced to powder. It is nearly entirely soluble in water and in alcohol. Vauquelin analyzed that sort which is termed African, and found it to consist of 75 per cent. of tannin, 24 of red mucilage, and 1 of woody fibre. Indian kino is said to be the produce of *Pterocarpus Morupium*; and African kino that of *Pterocarpus erinaceus*.

KINROSS. [KINROSS-SHIRE.]

KINROSS-SHIRE, a small inland county of Scotland, bounded E. and S. by Fifeshire, and W. and N. by Perthshire. It lies between $56^{\circ} 9'$ and $56^{\circ} 18'$ N. lat., and between $3^{\circ} 14'$ and $3^{\circ} 35'$ W. long. Its greatest length E. to W. is 12 miles, and its greatest breadth N. to S. is 10 miles. The area is 78 square miles, or 50,560 acres, of which about 30,000 are arable, 3000 wood, and 3327 water—

the latter consisting principally of Loch Leven. In 1861 the population was 7977—3779 males and 4198 females—in 1851, 8924. At the time of the census there were in the county 1644 inhabited houses, 100 uninhabited, and eight building.

The borders of the county are hilly, but the interior, comprising about one-half of the whole, forms a natural hollow round Loch Leven; based on coal and limestone rocks. The soil is various, chiefly inclining to sand and gravel. Some portions consist of a clayey loam, and are tolerably fertile, but in the more elevated parts the surface consists of moorland, and forms excellent pastures. Throughout the county the land is well cultivated; but the soil is least fertile where it rises towards West Lomond Hill, which is on the Fifeshire side, 1727 feet high. The better lands are inclosed; and oats, barley, and turnips are the chief crops. The climate, though cold, owing to the general elevation of the land, has been rendered much drier by an extensive system of drainage.

There is some coal in the south, where the county borders on Fifeshire. There are also freestone quarries of good quality in that quarter. To the north of Kinross red freestone is the geological formation of the district. The higher hills are whinstone or basalt. Some cotton and woollen goods are made; but the manufactures are unimportant.

This county contains several fresh-water lakes, some of which are well stocked with pike, and the rest with perch, eel, and other fish. Of these lakes the principal is *Loch Leven*, which although inferior in magnitude and picturesque beauty to Loch Lomond, is still a noble piece of water, covering a surface of nearly 3300 acres. Its height above the level of the sea is about 360 feet. Its greatest depth is from 80 to 90 feet, and its circumference about 11 miles, a partial drainage having reduced it 3 miles. It contains several islands, on one of which, in its midst, called Castle Island, Mary Queen of Scots was imprisoned in 1567–68, and signed her abdication on July 4, 1567, and from which, on May 2, 1568, she made her escape, shortly before the battle of Langside. The lake abounds in fish, among which the excellent gray trout is highly prized.

The chief streams are the Garry, the South Queich, and North Queich, all of which fall into Loch Leven. The waters flowing from the loch form the river Leven, which, after a course of about 14 miles, passing through a part of Fifeshire, falls into the Frith of Forth at Largo Bay.

Kinross was included in Fifeshire down to 1426. It is the smallest but one of the Scottish counties. There is a ruined castle at Burleigh. The county is divided into four whole parishes, and portions of three others; one presbytery in the synod of Fife; and has one small debt court. It joins with Clackmannanshire and four neighbouring parishes in Perthshire, in returning one member to Parliament. Electors on the county register in 1869, 550. The only towns in the county are the following:—

Kinross, the county town, is situated on the western shore of Loch Leven, 19 miles N.N.W. from Edinburgh. The lower part of the town is mean, but it rises towards the north, where there are many handsome houses. There is a modern parish church,

a county hall and gaol, town-hall, &c. Some manufactures of cotton, tartan shawls, plaids, and damasks, are carried on. The town communicates by railway with Dunfermline, Stirling, and the North British line. The population of the entire parish of Kinross at the census of 1861 was 2649; within the limits of the town only 2083.

Milnathort, 2 miles N. from Kinross, has a market on Wednesdays, though it is only considered a village. Population 1476, included in the parish of Orwell.

KINSALE. [CORK.]

KINTORE. [ABERDEENSHIRE.]

KIOSK, a Turkish word for an open pavilion or summer-house, supported by pillars, which is now becoming a favourite ornament of European gardens.

KIPPIS, ANDREW, D.D., F.R.S., born 1725, died 1795, was educated in a dissenting academy at Northampton. After a few years spent in the exercise of his ministry at Boston in Lincolnshire, and at Dorking in Surrey, he settled in London, in 1753, as pastor of a congregation of Presbyterian dissenters in Westminster. In 1763 he became tutor in an academy for the education of dissenting ministers in London. In 1771 he was elected a fellow of the Society of Antiquaries, and in the next year a fellow of the Royal Society.

Dr. Kippis was a principal contributor to the *Monthly Review* and the *New Annual Register*. But the work with which his name is most honourably connected is the republication of the 'Biographia Britannica,' with a large addition of new lives, and a more extended account of many persons whose lives were included in the former edition.

KIRKALDY. [FIFESHIRE.]

KIRKBY LONSDALE. [WESTMORELAND.]

KIRKCUDBRIGHT, THE STEWARTRY OF, is a maritime county in Scotland, bounded N. and N.W. by Ayrshire, E. and N.E. by Dumfriesshire, from which it is in part separated by the river Nith, S.W. by Wigtonshire and Wigton Bay, and S. and S.E. by the Solway Frith. It lies between 54° 43' and 55° 19' N. lat., and between 3° 33' and 4° 34' W. long. Its length E. to W. is about 48 miles; its breadth varies from 17 to 30 miles. The area is 954 square miles, or 533,760 acres, of which nearly one-third is arable, and 8000 under water. In 1861 the inhabitants numbered 42,495—19,789 males, and 22,706 females—who were living in 7326 houses. There were 233 uninhabited houses, and 66 building in the county; in 1851 the population was 43,121.

The coast, except in the upper part of Wigton Bay, is generally bold and precipitous. The surface of the county is rugged and barren, more particularly towards the sea coast. About two-thirds of the surface are mountainous. The chief elevations are Blacklurg in the north, which rises to the height of 2890 feet above the sea; Cairnsmuir in the west, 2892 feet; and Criffel, a detached granite mountain on the shore of the Solway Frith, 1831 feet.

The soil is thin, but improved by shell marl, &c., on the coast and along the rivers, where the best land is found. When well manured, the ground is often very productive. Abundance of good marl is furnished by upwards of thirty lakes which dot this county. The largest is Loch Ken, of great length, but extremely narrow. The climate is moist, and, except in the uplands, very mild.

The farms throughout the country are of moderate size, with improved buildings, and generally let on nineteen years' lease. Large numbers of cattle (the polled Galloway breed) and hogs are bred and fattened for the Liverpool, London, and other markets. The pastures are excellent. The sheep kept in the moors are mostly black-faced; Southdowns, Cheviots, and Leicesters are numerous in the mountains, and common in the lowlands. The small native hardy Galloway nags have been superseded by draught horses of a larger size, though some remains of the pure and valued breed of Galloway horses still exist. The parish of Borgue is noted for its superior horse.

Oats are the grain chiefly cultivated. The potato crops are considerable, and constitute a principal article of export to England, after supplying the inhabitants and feeding a great number of swine. Turnips, wheat, and barley are also grown.

Granite, porphyry, and grauwacke are the prevalent rocks. From the excellent granite quarried at Cree-town the new docks at Liverpool were constructed. A little iron and lead has been found; slate, limestone, sandstone, and millstone exist in various parts. Besides the numerous lakes, there are two principal streams, the Dee and the Urr. The former has its source near the north-western boundary of the shire, and falls into the Bay of Kirkcudbright. The salmon fisheries on this river are valuable. The Urr rises in a lake of the same name on the borders of Dumfriesshire, and discharges itself into the Solway Frith. The county does not possess any manufacture of importance.

There are some useful mineral springs. Good roads, and stone inclosures, called Galloway dykes, are common. Some fragments of an ancient stone dyke, or boundary, which was 8 feet broad and 50 miles long, yet remain in the uplands.

The county is now traversed by the Portpatrick branch of the Glasgow and South-Western Railway.

Kirkcudbright (pronounced 'Kirkewbree') was the seat of the Selgova and Novantes in the Roman province of *Valentia*. A Roman way can still be traced across the northern extremity. Drumore, near Kirkcudbright, is supposed to be the site of *Caerbantorium*.

In the eighth century the present country became part of Galloway, so called from the Irish Scots of Gaelic extraction, who settled here. There are many remains of British, Roman and Pictish camps, and stations, cairns, &c., with a Logan stone in the Kells range; Druid stones at Mennigaff; besides the ruins of New Abbey, Dundrennane Priory, Anworth and Lincluden churches, Kennure, Threave, Cardonness, and several other castles.

The condition of the rural population and the state of agriculture in this county up to the end of the last century were very primitive. The principal food, even in the early part of the present century, was chiefly kail, and oats ground in querns, turned by the hand, and dried in a pot. Before the Reformation it possessed more monasteries than any other county in Scotland.

Kirkcudbright is divided into twenty-eight parishes and one presbytery in the synod of Galloway. It contains two royal and parliamentary burghs (Kirkcudbright and New Galloway), and six small debt courts. The number of electors in the county is

1869 was 1883, who return one member to the House of Commons.

The principal towns, with the population of each in 1861, are the following:—

Castle-Douglas, a burgh of barony, situated near the centre of the county in the parish of Kelton, has a very large weekly market for agricultural produce. This town is quite modern, and has increased with great rapidity. The streets are wide, and cross each other at right angles. There is a town-hall, and the post-office embraces a wide extent of delivery, with many sub-offices. Population, 2261.

Gatehouse-of-the-Fleet, a municipal burgh, and river port in the parishes of Anworth and Girthon, is situated chiefly on the east bank of the river Fleet, near its entrance into Wigton Bay. A bridge crosses the river, and about one-fifth part of Gatehouse is on the west bank. Vessels of 180 tons can come up the river to this town, a distance of about 3 miles from the mouth. A canal about a mile long abridges the length of navigation. The town is 5 miles N.W. of Kirkcudbright. Population, 1635.

Kirkcudbright, the county town, is situated on the eastern bank of the estuary of the Dee, about 6 miles from the mouth of the Bay of Kirkcudbright, and 101 miles S. by W. from Edinburgh, and 10 miles from the Castle-Douglas station of the Glasgow and South-Western Railway, with which it is connected by a branch. It was anciently a burgh of barony, but it was erected by James II. into a burgh of regality in 1455. The river opposite the harbour is 20 feet deep at neap tides, and 400 feet wide. Coal and lime are imported from Cumberland in large quantities, and some timber from abroad. Wheat, oats, potatoes, and other agricultural products, are exported. Population in 1861, of the entire parish, 3407; of parliamentary burgh, 2552; of municipal, 2638. The number of the parliamentary and municipal constituency is 180. It is governed by a provost, two bailies, and seventeen councillors. Quarter sessions, stewartry, and small debt courts, are held here; it is the head of a poor-law union, and the seat of a presbytery. The town is well built. Its principal buildings are—a handsome church, lately rebuilt; court-house, custom-house, town-hall (1508), gaol, market-house, water-works, grammar-school, and union workhouse. There are remains of an old castle of the lords of Kirkcudbright in the middle of the town, with several British and Roman works in the neighbourhood. Besides the parish, there are Free and United Presbyterian churches; and a Roman Catholic chapel; a mechanics' institute, with library and reading-room, and large hall above (one of the finest rooms in the south of Scotland). The Dee is spanned by a magnificent viaduct at Tongland. Although the harbour is the best in the south of Scotland, the town has but little trade beyond the employment of a few cotton looms, some shipbuilding, &c. The scenery around the town is very beautiful, the rising grounds on each side the river, from Tongland to the sea, being embellished with plantations. About a mile distant is St. Mary's Isle, the beautiful seat of the earl of Selkirk, where are some of the largest trees in the country. Education is very cheap, and Kirkcudbright has long been noted for its schools. It has a free school, which is attended by a large

number of children, endowed by one of the inhabitants, and called the 'Johnston Free School.' The borough unites with Dumfries, Annan, Lochmaben, and Sanquhar in returning one member to Parliament. Steamers ply from hence to Liverpool.

Maxwell-Town, a burgh of barony, is situated on the west bank of the Nith, opposite Dumfries, with which it is connected by two bridges. The streets of the old part of the town are narrow and crooked; those of the new part are straight, and sufficiently wide. There is a court-house, beneath which is a gaol. There are two foundries, two roperies, a damask manufactory, and four nurseries, in which grapes and other rarer fruits are raised by artificial heat in great perfection. Population, 3599.

New Galloway is a royal and parliamentary burgh in the middle of the county, 19 miles N.W. of Kirkcudbright, in the parish of Kells, and 14 miles from the railway at Castle-Douglas. The population of the entire parish of Kells is 1167; within the limits of the parliamentary borough of New Galloway, 462; of the royal burgh, only 452. The number of voters is of course very small—only thirty. New Galloway contains a church, town-house, and gaol; and belongs to the heirs of the late Lord Kenmare, of Ken Castle. It takes its name from the district of Galloway, on the borders of which it stands, near Loch Ken. It was first chartered in 1629; is governed by a provost, two bailies, and nine councillors; and is the seat of steward, commissary, and small debt courts. This place unites with Wigtown (24 miles distant), Stranraer, and Whithorn (all in the county of Wigtown), in sending one member to the House of Commons.

KIRKDALE CAVE. This cavern in the oolitic limestone, not far from Kirkby Moorside in Yorkshire, is remarkable for a great quantity of bones, chiefly of extinct animals, which were found in it, and which gave occasion to the publication of Dr. Buckland's geological work, the 'Reliquiæ Diluvianæ.' It was discovered in 1821, and had a nearly level floor, parallel to the limestone strata. Its extent was 245 feet; the height varied from 3 to 6 feet or more. On the rocky floor was generally a bed of mud, covered over by an irregular layer of sparry stalagmite, formed by the dropping of water containing carbonate of lime in solution; and it was in this stalagmite and in the mud below it that the bones were found. Of the animals to which the bones belonged 6 were Carnivora, hyena, felis, bear, wolf, fox, weasel; 4 Pachydermata, elephant, rhinoceros, hippopotamus, horse; 4 Ruminantia, ox, and three species of deer; 4 Rodentia, hare, rabbit, water-rat, mouse; 5 Birds, raven, pigeon, lark, duck, snipe. The bones were almost universally broken. The remains of hyenas were the most abundant of all the bones; their teeth were found in every condition, from the milk tooth to the old worn stump.

KIRKHAM. [LANCASHIRE.]

KIRK SESSIONS. [SCOTLAND.]

KIRKWALL. [ORKNEY.]

KIRRIEMUIR. [FORFARSHIRE.]

KIRSCHWASSER (Ger.), 'cherrywater,' a kind of spirit made from black cherries, and much esteemed in Germany. The cherries, kernels and all, are pounded and broken in a vessel, and left to ferment for some days. The liquor is then obtained by dis-

tillation, and flavoured occasionally with hydrocyanic acid. Kirschwasser is sometimes called 'cherry brandy,' but the ordinary cherry brandy is made by mixing brandy with the juice of cherries.

KIRTLE, in the feudal ages, a sort of coat of mail, or surcoat. Sometimes it was short; but that of the knights of the Bath reached to the heels.

KIRWAN, RICHARD, was born in Ireland about the middle of the last century, and died in 1812. He was for some time president of the Royal Irish Academy, and was elected member or associate of most of the literary societies of Europe. His memoirs are diffused through the 'Transactions' of the Royal Society of London, those of the Royal Irish Academy, and other publications. One of his most remarkable separate works was 'An essay on the Constitution of Acids.'

KISHENAU or KICHENEV, the capital of Bessarabia in Russia, on the Buik, a feeder of the Dniester, 95 miles N. W. of Odessa. When it came into the possession of Russia in 1812 it was a small wretched place, but it has since increased more rapidly in proportion than any other town in the empire; the population having been 94,124 in 1863. It covers three hills, has about twenty churches, and some handsome public buildings and manufactures of woollen cloth, brandy, and leather, and a very extensive trade in corn, cattle, flax, and hemp.

KISSINGEN, a town of Bavaria, in Lower Franconia, noted for its mineral springs. They are both acidulous and chalybeate, and not only is the water used for drinking and bathing, but about 500,000 bottles are annually exported. The town is visited by large numbers of English. The resident population is only about 2000. Near the town are salt mines, from which 30,000 cwt. of salt are raised yearly. The gambling tables were suppressed in 1848.

KIT-CAT, a term applied to a Whig political club in London, founded about 1688, to which Addison and Steele belonged, so called from Christopher Cat, a pastry-cook who served the club with mutton pies. Sir Godfrey Kneller, a member of the club, painted a series of portraits of all the other members, which were hung up in the room of meeting. To accommodate the paintings to the height of the walls he was obliged to adopt a new size of canvas; hence Kit-cat is generally applied to any portrait about three-quarters of the figure in length.

KITCHEN-GARDEN. In laying out the grounds of a country residence provision should be made for the site of the kitchen-garden. Though it should not obtrude on the ornamental ground immediately adjoining the house, the design of the whole should be so formed as to leave the kitchen-garden in the most favourable situation with regard to aspect, soil, and water. The aspect should be open to the south, but sheltered on other sides, more especially from northerly and easterly winds, by rising ground or lofty trees at some distance. The surface should be nearly level, or in some cases, according to the pervious nature of the subsoil, it may be quite so; but, generally speaking, a gentle slope from north to south is best. The soil should consist of a rich loam, neither too light nor so adhesive as to be liable to bind strongly in dry weather. The depth of soil ought

not to be less than two feet, and more is absolutely necessary for some kinds of vegetables.

Much injury is done to vegetation by watering with cold spring water, or indeed with any water that is much colder than the soil and atmosphere in which the plants are placed. Plants, when not watered at all in dry weather, if they are only kept alive, succeed better when rain does come than others that are watered, or rather chilled with water, at a comparatively low temperature. Water for the kitchen-garden should therefore be derived from ponds or large reservoirs fully exposed to the sun, and even these should be supplied by open rather than underground channels.

The quantity of ground which a kitchen-garden should contain must be regulated according to the number of individuals which it is required to supply. An acre is calculated to afford a tolerable supply for sixteen individuals, but much depends on the nature of the vegetables required. Potatoes, turnips, peas, and carrots are frequently obtained of better quality and at less expense from a field than from a garden.

The form of a kitchen-garden should be composed of straight lines. If rectangular, it will prove a saving of labour; for it is practically known that more time is required to trench a piece of ground of a triangular form than if the same extent were in the shape of a square or parallelogram. A range of forcing-houses is generally placed on the north side; and as the wall on that side is the most valuable for fruit-trees, on account of its direct south aspect, it becomes desirable that it should be extended as much as possible on one or both ends of the range.

The interior departments of the kitchen-garden are usually bounded by fruit-trees planted within two or three feet of the walks. Not only are bushes, such as gooseberries, currants, and raspberries, used for this purpose, but fruit-trees of various kinds. The latter are trained either as dwarfs by grafting apples on paradise stocks, and pears on quinces, and causing their branches to proceed from near the ground, or as espaliers. They were formerly much more in use for training fruit-trees in kitchen-gardens than they are at present, as many object to their appearance, and others to their utility, as compared with their expense.

Very few of the subjects of kitchen-garden cultivation are indigenous; they are chiefly varieties of luxuriant habits, which are artificially maintained and augmented by the art of the cultivator. The principal means employed for rendering the soil of the kitchen-garden subservient to this purpose are: the application of abundance of manure; trenching, digging, and otherwise stirring the soil; and a due rotation of crops. Manure supplied in abundance will generally produce luxuriance in vegetables, although sometimes a disagreeable rankness is communicated to the flavour. This is in a great measure corrected by trenching, which becomes occasionally highly necessary; and although expensive, it will always repay the cost, if judiciously performed, particularly if the soil be of a consolidating nature.

It is always advantageous to attend to a proper rotation of crops, especially where manure is not abundantly applied, nor trenching performed. One kind of plant should not immediately follow another of the same nature, or one closely allied.

KITE. [FALCONIDÆ.]

KITTIWAKE, the popular name for one of the gulls, *Laridæ*. It is the *Larus rissa* of some ornithologists, and the *L. tridactylus* of others. It frequents the British coasts at the breeding season, but leaves in winter. It arrives on our coasts in March, and departs in October. In Scotland its favourite breeding places are on the shores of the northern Hebrides. It is a beautiful bird. The plumage is full, close, and elastic. The bill is a pale yellowish green. The head, neck, all the lower parts, the fore part of the back, and the upper tail-coverts are white. The back, the upper surface of the wings, and the scapulars are a light bluish-gray. The length of the bird is about 17 inches, the extent of the wings 36.

KITTO, JOHN, the eminent self-taught biblical scholar, was born at Plymouth, 4th December, 1804. Through the intemperance of his father his childhood was passed in poverty, so that he got no schooling worthy of the name. Having, however, through his grandmother's kindness learned to read, he devoured all the nursery literature within his reach. When he was about ten years of age he was set to work as assistant to his father, who was a mason. On the 13th of February, 1817, the little drudge, who was engaged carrying mortar and slates, missed his footing and fell from the roof of a house. Long he lay in bed afterwards, and by the accident his sense of hearing was completely extinguished. He resorted to various contrivances to gain a livelihood, groping for bits of rope and iron in Sutton pool, painting heads and flowers, &c. The love of reading still grew upon him, victim though he was of hunger and nakedness, and at length the starved and ragged lad was admitted into Plymouth workhouse. In the workhouse he kept a journal—a curious record of his history and privations. The various writings of the pauper youth began to attract attention; a subscription was made for him; and he left the hospital in which he had been an inmate for about four years. Mr. Groves, then a dentist in Exeter, took him under his charge as an apprentice; and during his stay at Exeter, and in his twentieth year, he published a small volume of essays. Kitto then went to the Missionary College in Islington to learn printing, with a view to mission work abroad. Malta was selected as his field of labour, and there he resided eighteen months. On his return he found Mr. Groves preparing to go as a missionary to the East, and he at once agreed to go with him as tutor to his children. Mr. Groves and his party reached Bagdad on the 6th December, 1829, and Kitto remained till September, 1832. During his stay in Bagdad the city was besieged; the plague broke out and carried off fifty thousand of the population in two months; and the river overflowed its banks, throwing down seven thousand houses. Kitto came home by way of Constantinople, and arrived in England, June, 1833, having kept a pretty full journal of his Eastern travels. He began at once to write in the *Penny Magazine*, and Mr. Knight engaged him for the *Penny Cyclopædia*. His travels had furnished him with a knowledge of Oriental customs and peculiarities, and he projected the Pictorial Bible, which was published in monthly parts, and finished in May, 1838. It rose at once into high popularity. The 'Pictorial History of Palestine'

followed; the 'Christian Traveller,' of which a few parts only were published; the 'History of Palestine,' the 'Cyclopædia of Biblical Literature,' the 'Pictorial Sunday Book,' and the 'Lost Senses,' containing virtually an autobiography of great interest. Then came the 'Journal of Sacred Literature,' to which he gave much of his time; and finally the 'Daily Bible Illustrations,' in eight volumes, and dedicated to the queen. But before this work was concluded he had fallen into bad health. To secure him some relaxation a sum of money was raised among his friends—a pension of 100*l.* from the civil list having been previously conferred upon him. Broken down and exhausted from constitutional debility and excessive labour, he repaired to Germany and finally settled at Canstatt on the Neckar. Recovery was hopeless, his days were clouded by family bereavement, and after some hours of severe convulsions he died on the morning of the 25th of November, 1854. The University of Giessen conferred upon him, though a layman, the degree of D.D. in 1844, and in the following year he was elected a fellow of the Royal Society of Antiquaries.

KIZIL ERMAK. [ANATOLIA.]

KLAGENFURT. [CLAGENFURT.]

KLAPROTH, MARTIN HEINRICH, was born at Wernegerode in Upper Saxony, on December 1, 1743. After passing seven years in the public laboratory at Quedlinburg, and two years in that of Hanover, he went to Berlin, and in 1770 to Danzig; he afterwards returned to Berlin as an assistant to Valentine Rose, one of the most distinguished chemists of the day, and on his death in 1771 he succeeded him. In 1780 he underwent the necessary forms and examinations for the profession of an apothecary. His thesis 'On Phosphorus and Distilled Waters' was printed in the 'Berlin Memoirs' for 1782.

His various analyses and contributions to chemical science were collected in 1796, under the title of 'Contributions to the Chemical Knowledge of Mineral Bodies;' the last and sixth volume appeared in 1815, about a year before the death of the author. He died at Berlin, January 1, 1817.

KLAPROTH, JULIUS HEINRICH VON, the son of the former, was born at Berlin on the 11th of October, 1783. He learned Chinese secretly without the help of a master. His father, perceiving that he devoted his time exclusively to Oriental languages, sent him, in 1801, to the University of Halle, to study the classical languages. He remained several years at Halle, when the learned Count John Potocki proposed to him to enter the service of the Emperor Alexander of Russia. Upon his arrival at St. Petersburg, early in 1805, the Russian government being then engaged with the plan of sending an embassy to China, Count Potocki obtained for Klaproth the place of an interpreter. He set out alone, and after having traversed the Ural Mountains, arrived at Irkutsk. On the return of the embassy, Klaproth took a solitary route through Southern Siberia, and only reached the Russian capital in the beginning of 1807. Before the end of the year he was sent on a scientific mission to the Caucasian provinces. He returned in January, 1809, with a large stock of information, most of which afterwards formed the subject of separate works and articles in learned periodicals. During his stay in Russia he was active in establishing a school of

Oriental languages at Wilna, and in making a descriptive catalogue of the Chinese and Mantchu MSS. in the imperial library at St. Petersburg. He was sent in 1811 to Berlin, to superintend the engraving of the characters which were intended for printing those MSS. In 1812 he tendered his resignation to the Russian government, and after some time received permission to leave. After various vicissitudes and changes of residence, Klaproth finally settled at Paris, where, enjoying an income which enabled him to gratify his love of pleasure and refined society, he exhibited an extraordinary activity, and it was in the years subsequent to 1816 that he published most of those literary productions which established his reputation. After long and painful sufferings he died suddenly, on the 27th of August, 1835.

Klaproth was one of the best scholars and decidedly the best linguist of an age which can justly boast of great linguists. His penetration, sagacity, and the quickness of his perception, were extraordinary; clearness and perspicuity distinguish his style; and his memory was so happy and capable of retaining the most different impressions without ever confounding them, that he seldom made more than scanty extracts. When he began a work, it was already clear and distinct in his mind, and the composition did not take him more time than was required for the mechanical art of writing.

(*Biog. Universelle; Neuer Nekrolog der Deutschen; Querard, La France Littéraire.*)

KLARENTZA, or CHIARENTZA, a seaport village and mountain fortress of Greece, at the western extremity of the Morea, near the cape of the same name, 17 miles N.E. of Zante. In the Middle Ages it formed a principality, which was inherited by a son of Edward III. of England, and from this junior branches of the royal family of England have since repeatedly borne the title of Duke of Clarence.

KLAUSENBURG, or KOLOSVAR, one of the two royal and free capital cities of Transylvania, is on the Szamos, 73 miles N.N.W. of Hermannstadt. It consists of the old and new towns, and several suburbs; is surrounded by walls, and entered by six gates. The population is 21,346; and the city is the seat of the Transylvanian Diets, of the Unitarian superintendence for Transylvania, and of a Protestant consistory. The chief manufactures are woollens, china ware, and paper. The principal public buildings are—a citadel, a cathedral, Roman Catholic, Calvinist, Unitarian, and Lutheran churches; a town-hall, military and other hospitals; and there are also Roman Catholic, Reformed, and Unitarian colleges; Piarist and other monasteries, and an institute for nobles. This town was the birthplace of Mathias Corvinus, king of Transylvania.

KLEBER, JEAN BAPTISTE, according to the best authorities, was born at Strasbourg in the year 1754. He was brought up to the profession of an architect, and sent to Paris at an early age to complete his studies; but he soon left Paris for Munich, where he entered the military college of that city. He was afterwards appointed to a sub-lieutenancy in an Austrian regiment. He served seven years in that corps, which he left in 1783, in order to return to his native country. He there resumed his former profession, and obtained the situation of inspector of public buildings at BÉFORT in Upper Alsace.

The breaking out of the French revolution opened to him a more brilliant career. He enlisted as a private soldier in the grenadier company of the battalion of volunteers which had been raised in the department of the Upper Rhine. By his bravery and talents he soon attained the rank of adjutant-major. At the siege of Mainz, in 1793, he displayed considerable courage and judgment: his services were rewarded by the rank of adjutant-general, and shortly afterwards he became brigadier-general. He continued in active employment, and to rise in rank, until at the battle of Fleurus (June 26, 1794) he commanded the left wing of the French army, and by his skilful manoeuvres greatly contributed to the victory. When Bonaparte was appointed to the chief command of the army for Egypt, he made it a special request to the Directory to be allowed to take him as one of his generals of division. He continued to act with Bonaparte throughout the campaign in Egypt, and when, after the repulse from Acre in 1799, Bonaparte resolved to return to France, he appointed Kléber his successor. He did not, however, at first justify the favourable opinion formed of his talents for command. He seemed to despond, and opened a communication with the Grand Vizier for evacuating Egypt. After many debates and frequent delays, a convention was signed at El Arish, on January 28, 1800, by which it was agreed that the whole of the French army should return to Europe, with its arms and baggage, either on board their own vessels or some furnished by the Turks. The English admiral, Sir Sidney Smith, though not vested with full authority from his government to conclude such a convention, had entered into it. The British government had, however, previously despatched orders to Lord Keith to refuse his consent to any treaty in which it was not stipulated that the French army should be considered prisoners of war; and a letter from this admiral reached General Kléber, warning him of his intention to detain any vessel returning to Europe by virtue of a capitulation. The French commander immediately ordered the evacuation of the strongholds to be stopped, and prepared to resume hostilities. On the night of March 19, 1800, Kléber drew up his army, which was 12,000 strong, on the plain fronting the ruins of Heliópolis. Before them was the Ottoman army, amounting to upwards of 40,000 men. The contest commenced, and after an obstinate fight the Turks were defeated with great slaughter, Cairo was occupied, and the Mameluke commander, Mourad Bey, concluded an honourable convention with the French commander. Thus, within a month of the battle of Heliópolis, the French were again in possession of their previous conquests.

Released from immediate danger, Kléber now began to direct his energies to more pacific labours, and to apply them to the administration of the conquered country, but on June 14, 1800, he was assassinated by a religious fanatic named Suleiman, and with him perished the hopes of the Eastern expedition.

KLOPSTOCK, FRIEDRICH GOTTLIEB, was born at Quedlinburg in 1724, of respectable parents. In his sixteenth year he went to the school at Naumburg, where his poetical character was first developed. In 1745 he studied theology at Jena, where he projected the design of his 'Messiah,' and in 1748 the

first three cantos appeared. The excitement created by this poem was surprising. He composed in 1764 his 'Hermannsschlacht' ('the battle of Arminius'), which is scarcely so much a drama as a lyric poem in a dramatic form. His other dramas are of a similar character. In 1771 he settled at Hamburg, where he completed his 'Messiah.' His 'Odes' are generally more read and valued than his 'Messiah' or his dramas. He died in 1803.

KMETY, GEORGE, was the son of a Protestant clergyman, and was born on one of the southern slopes of the Carpathians, in May, 1813. He had such a passion for a military life that he enlisted as a private in the Austrian army, and in spite of the great difficulties in the path of any one without interest or money, he rose to the rank of captain. On the breaking out of the Hungarian revolution in 1848, he succeeded in raising the best battalion in the Hungarian service, and played a conspicuous and noble part during the whole of the war, his corps firing the last shot at the village of Farcet. He afterwards entered the Turkish army, and greatly distinguished himself at the siege of Kars. The campaign, however, ruined his health, and he was obliged to retire from the service. The Turkish government granted him a liberal pension, which enabled him to reside as a private gentleman in London for some years. He died April 25, 1865.

KNAPPIDIA, a genus of plants belonging to the natural order *Gramineæ*. There is only one species of Knappidia, *K. agrostioides*, an elegant but very small grass, with a small fibrous root, having numerous stems and short rough leaves. It is found in sandy maritime pastures, but is a rare grass.

KNARESBOROUGH. [YORKSHIRE.]

KNAUTIA (named after Christopher Knaut, a German botanist), a genus of plants belonging to the natural order *Dipsacæ*. There are a few species of *Knautia* natives of Europe. The only British species is *K. arvensis*, with purple flowers, in large convex long-stalked heads.

KNEB'ELITE, a hard and brittle mineral, of grayish colour, and spotted with red, green, brown, and white. It occurs massive, with a glistening lustre; and its constituents are—silica, protoxide of manganese, and protoxide of iron, nearly in equal proportions. It was so called in honour of Major Von Knebel.

KNELLER, SIR GODFREY, was born in 1646, in the city of Lübeck, and received his first instruction in the art of painting in the school of Rembrandt. He afterwards became a pupil of Ferdinand Bol. At Rome, Venice, and Hamburg he met with very great success. In London he was state painter to Charles II., James II., William III., Queen Anne, and George I.

Kneller had much of the freedom of Vandeyck, but less nature. His beauties of the court of William III. are inferior and tame, in comparison with Sir Peter Lely's beauties of the court of Charles II. Sir Godfrey died in 1723, aged seventy-eight.

KNIGHT, KNIGHTHOOD (Saxon, *cniht*; German, *knecht*.) During the feudal system the military strength of the nation was measured by the number and efficiency of the knights whom the king was able to summon to the field. By distress the king could compel those who held knight's fees

[FEUDAL SYSTEM] to take upon themselves the order of knighthood, or to prove by their reception into that order that they had received the training, and possessed the arms and accoutrements, and were as to other requisites qualified to take the field as knights.

That power of distraining upon persons till they received knighthood, or compounded with the king by way of fine, which originally was a means of enforcing the performance of a duty to the Crown, by persons holding a certain property in the country, was perverted into a process for extorting money from those who would have been exempt at common law, which regulated the amount of a knight's fee by the sufficiency of the land to support a knight, and not by its fluctuating nominal value in a debased currency. This oppressive proceeding, which was occasionally resorted to in the reigns of Edward VI. and Elizabeth, was reduced into a system by Charles I., and was adopted by him as one of the modes of raising money without resorting to a parliament. [KNIGHT'S SERVICE, TENURE BY.] The manner in which this ancient prerogative was abused led to its total abolition. By 16 & 17 Car. I., c. 20, it is enacted that none shall be compelled, by writ or otherwise, to take upon him the order of knighthood, and that all proceedings concerning the same shall be void.

Knighthood in England is now conferred by the Crown by simple verbal declaration, attended with a slight form, without any patent or other written instrument. Sometimes, but rarely, knighthood is conferred on persons who do not come into the presence of royalty. This is occasionally done to governors of colonies, and other persons in high stations abroad. The lord-lieutenant of Ireland has a delegated authority of conferring this honour.

Knighthood gives precedence over esquires and other untitled gentlemen. 'Sir' is prefixed to the baptismal name of knights and baronets, and their wives have the legal designation of 'Dame,' which is ordinarily converted into 'Lady.' Knighthood, however, is not hereditary, but merely personal.

Besides those who are simply knights, there are knights who are members of particular orders or classes. These orders exist in most of the kingdoms of Europe, and have had generally for their founder a sovereign prince. The three British orders, the Garter, the Thistle, and St. Patrick, belong to this class. [GARTER, ORDER OF.]

The order of the Thistle was instituted in 1540, by James V., king of Scotland; but it fell into decay, till in the reign of Queen Anne, 1703, it was revived. The number of knights was limited to thirteen, but in 1827 the number was increased to sixteen, all of whom are nobility of Scotland.

The order of St. Patrick was instituted in 1783. The knights were fifteen, increased in 1833 to twenty-two, who are peers of Ireland.

The order of the Bath differs in some respects from those just spoken of. [BATH, KNIGHTS OF.]

The order of the Star of India, and the Order of Valour, or the Victoria Cross, have been founded of late years for objects indicated by their respective titles. [VICTORIA CROSS.]

KNIGHT OF THE SHIRE is the designation given to the representative in Parliament of English

counties at large, as distinguished from such cities and towns as are counties of themselves (which are seldom, if ever, called shires), and the representatives of which, as well as the members for other cities and towns, are denominated citizens or burgesses. Formerly it was requisite that they should be knights girt with the sword, now notable esquires may be elected. The wages payable to knights of the shire for their attendance in Parliament, including a reasonable time for their going up and coming down, were 4s. a day, or double what was received by citizens and burgesses. At the close of every session of Parliament, the king, in dismissing them to their homes, informed them that they might sue out writs for their wages, upon which each knight separately obtained a writ out of Chancery directed to the sheriff, mentioning the number of days and the sum to be paid, and commanding the sheriff to levy the amount. Upon this the sheriff, in a public county court, divided the burden among the different hundreds and townships, and issued process to levy the amount, which, to the extent of the money levied, he paid over to the knight. Knights of the shire, and also their electors, were formerly required to be persons either resident or having a household in the county. This regulation, though confirmed by several statutes, had fallen into neglect, and was formally repealed in both its branches by 14 Geo. III., c. 58. The removal of the latter part of the restriction has greatly added to the expense of county elections; and though the Reform Acts of 1832 and 1867 disfranchised out-voters in boroughs, they did not restore the old law as to non-resident county electors. By the 1 & 2 Vict. c. 48, every county member was to be entitled for his own use and benefit to an estate legal or equitable of the clear yearly value of 600*l.* in lands, tenements, or hereditaments, lying within the United Kingdom, or in the rents and profits thereof; or to the like estate in personality in the United Kingdom; or to an estate of the same value composed jointly of these several qualifications. The property qualification was, however, entirely abolished by 21 & 22 Vict. c. 26.

KNIGHTON. [RADNOR.]

KNIGHTON, HENRY, an English historian of the close of the fourteenth and beginning of the fifteenth century, was a canon-regular of Leicester Abbey. His '*Compilatio de Eventibus Angliæ à tempore Regis Edgari usque ad mortem Regis Ricardi Secundi*,' was published by Twysden in the '*Decem Scriptores*,' folio, London, 1652, col. 2311-2741.

KNIGHT'S FEE. [FEUDAL SYSTEM.]

KNIGHTS, MILITARY, an institution of military knights at Windsor, formerly called 'Poor Knights.' It is a provision for a limited number of old officers, chiefly veterans, and owes its origin to Edward III. It is composed of a governor and seventeen knights, who are allowed three rooms each in Windsor Palace, and 2s. per day (besides other allowances) for subsistence.

KNIGHT'S SERVICE, TENURE BY, otherwise called Tenure in Chivalry, or per Servitium Militaire, was, from the times immediately succeeding the Norman Conquest in the eleventh century to the period of the civil war in the seventeenth, considered the first and the most important, as it

was also the most general, mode of holding land in England. The land held by this species of tenure was said to consist of so many knights' fees, *feoda militis*, i.e., so many portions of land capable of supporting the dignity of a knight. [FEUDAL SYSTEM.] The duty attached to knight service was that of following the lord to the wars, according to certain rules.

Besides the liability to military service, the tenant by knight's service was subject to other occasional burdens. The principal of these are the following:—1. *Aids* [AIDS]. 2. *Reliefs*. 3. *Primer Seisin*. 4. *Wardship*. 5. *Marriage*. 6. *Fines upon Alienation*.

This system fell to the ground during the existence of the Commonwealth; and the abolition of this species of tenure was confirmed upon the Restoration by the 12 Car. II., c. 24, which converted all tenures by knight's service into free and common socage. [SOCAGE.] The statute, after taking away the court of wards and liveries, enumerates wardships, liveries, primer seisins, &c., and sweeps away the whole. But rents certain, heriots, suit of court, and other services incident to common socage and fealty, and also fines for alienation due by the customs of particular manors, are preserved. Reliefs for lands of which the tenure is converted into common socage, are saved in cases where a quit-rent is also payable.

Under the feudal system as observed in Scotland, tenure by knight's service was known by the name of *Ward-holding*. The burdens or *casualties* peculiar to this tenure were—1, *Ward*, the guardianship by the superior of the vassal during his minority. 2, *Recognition*, the return of the lands to the over-lord when the vassal had sold or alienated the whole or the greater part of them without his superior's consent; and 3, *Marriage*, which was a fine payable by the heir of the last vassal infeft on his being married or becoming marriageable.

Lands held *Ward* were further liable to the casualties common to all holdings. *Ward-holding* was abolished by 20 Geo. II. c. 50. [HOLDING.]

KNIGHTS TEMPLARS. [TEMPLARS.]

KNOT, a sea-faring term for a nautical mile of 2208 yards; there being sixty knots to a degree and three to a league. The knot is used for ascertaining the speed of a ship's sailing by means of the line-knots, which are placed at 50 feet from each other. It is then calculated that 120 times 50 feet make a geographical mile; and that as many knots will run from the reel in one trial as the vessel sails miles in an hour, the proportion of each length into which the line is divided being to a geographical mile as half a minute is to an hour, viz., as 1 is to 120. Note is then taken of how many of these knots run out in half a minute, and it follows that the vessel is passing through the water at the same number of geographical miles per hour.

KNOUT, an instrument of punishment used in Russia until recently for all kinds of criminals. It is a scourge made of several thongs of skin plaited, and interwoven with wire. It is only employed at the present time to whip assassins and those soldiers who have been dismissed from the army in disgrace. The punishment is usually inflicted by a criminal, who thereby earns exemption from exile to Siberia.

If as many lashes as 120 are given, the victim generally dies under the operation.

KNOWLES, JAMES SHERIDAN, was born in the city of Cork on the 12th of May, 1784. His father was a man of learning and ability, the nephew of Sheridan the lexicographer, and first cousin of the more distinguished Richard Brinsley Sheridan. The family removed to London in 1792, and here the boy James was educated, forming acquaintance, as he grew up, with Hazlitt, Coleridge, Lamb, Edmund Kean, and Macready. Knowles made his first appearance as an actor at Crow Street Theatre, Dublin, having previously written some minor poems and tragedies. He next joined a company at Waterford, and produced for Kean the tragedy of 'Leo the Gipsy,' his first acted play. He afterwards lived in Belfast and Glasgow as a teacher of elocution. In 1815 appeared his first successful play of 'Caius Gracchus,' which was followed by 'Virginius,' produced on the London stage by Macready, and identified with his genius. The drama of 'William Tell' appeared in 1825, establishing Knowles' reputation as a dramatist; this was succeeded by 'The Beggar's Daughter of Bethnal Green' and 'Alfred the Great.' Then came another triumph, 'The Hunchback,' produced at Covent Garden in 1832; quickly followed by 'The Wife' in each of which Knowles himself supported the principal character. He brought out the 'Love Chase' in 1837, which was played at the Haymarket for more than a hundred nights. At the instance of the Dramatic Authors' Society, a pension of 200*l.* a year was granted to him out of the civil list in 1843. His dramatic works are published in three volumes. In 1852 he became a Baptist preacher, published some controversial works, and distinguished himself by his religious zeal. He died at Torquay in Devonshire, 1st December, 1862.

KNOWLTONIA, a genus of plants belonging to the natural order *Ranunculaceæ*. The species are one-seeded perennial herbs, with greenish yellow flowers. *K. vesicatoria* is a plant the leaves of which are used as vesicants at the Cape of Good Hope. There are four other species, natives of the Cape of Good Hope, where these plants grow in abundance.

KNOX, JOHN, the famous Scottish reformer, was born at Gifford in East Lothian in 1505. His father was descended from an ancient family in Renfrewshire, possessed of the lands of Knock, Craighends, and Ranfurly—this last being now the title of an Irish earl, a descendant of the old house. His mother's name was Sinclair—a name which in days of danger he sometimes assumed, or 'wrait in time of trubill.' In his boyhood he attended the grammar-school at Haddington, and in 1522 his father sent him to the University of Glasgow. Mair, or Major, was his preceptor, being then professor of philosophy and theology. On Major's removal to St. Andrews during the following year, Knox seems to have followed him. Before his twenty-fifth year he was ordained a priest, though he had not reached the age fixed by ecclesiastical canons. But his mind grew weary of scholastic subtleties and refinements; he preferred studies more useful and practical in their nature. The popish theology did not satisfy him, and suspicions of his heresy were soon and easily

excited. Accordingly he retired to the south of Scotland, where he formally renounced the papal faith. His enemies in St. Andrews passed sentence against him, and ruffians were employed by Cardinal Beaton to assassinate him. After shifting his residence various times, he found an asylum in the house of Hugh Douglas, of Longniddrie, to whose sons, and those of the neighbouring proprietor of Ormiston, he acted for a brief period as tutor. His mind was profoundly impressed at this period by the preaching of Thomas Guillaume, a reformed Benedictine, and that of George Wishart, the saintly martyr. The persecution against the reformers did not pause at Beaton's death, though his tragic end produced a wide and deep sensation. But persecution did not check the progress of opinion and religious change in Scotland. The conspirators against Cardinal Beaton still held the castle of St. Andrews; and as it was reckoned a place of safety, Knox and his pupils took refuge in it at Easter, 1547. In the castle of St. Andrews Knox taught and exhorted so much to the satisfaction of his audience, that it was resolved to call him to the ministry as colleague to John Rough, who was chaplain to the garrison. Knox reluctantly, and after great mental distress, obeyed the call, and soon preached and disputed to the terror of all his priestly antagonists. Many of the inhabitants were then induced to abandon popery; and for the first time in Scotland, the Lord's Supper was publicly celebrated in Protestant form. But in the month of June a French fleet came to the assistance of the regent, and the castle, invested by sea and land, was forced to capitulate. Knox and some other persons were transported to Rouen, the terms of capitulation were violated, and at the instigation of the pope and the Scottish clergy, they were confined on board the galleys and loaded with chains. The galleys in which Knox and his fellows were confined sailed to Nantes, and lay all winter in the Loire. Every inducement was held out to the captives to recant; but cajolery and menace were alike in vain. The French vessels returned to the east coast of Scotland, probably in 1548. Knox had been seized with fever, and his life was despaired of; yet there was in his soul the inborn persuasion that God had some work for him to do in Scotland. At length, after a rigorous and unhealthy imprisonment of nineteen months, he was liberated in February, 1549. He repaired at once to England, was recommended to the English council, and sent down to preach in Berwick. For two years he laboured there, preaching the gospel, smiting Popery, and gaining over crowds of converts to Protestantism. Tonstall, bishop of Durham, summoned him to Newcastle. Thither Knox went, and with characteristic intrepidity delivered a pithy and thorough vindication before the bishop and his clergy. This appearance so increased his fame that he was transferred to Newcastle, and appointed one of King Edward's chaplains, with a salary of 40*l.* a year.

His undaunted preaching in the north of England raised up many bitter enemies, and by the influence of the ambitious and unprincipled duke of Northumberland he was summoned to London, and so nobly cleared himself of all imputation, or from what he himself styles 'heinous delations and numerous lies,' that he was at once acquitted. He preached before his majesty, who was greatly delighted with his

sermons; and the council ordered that next year he should be employed in London and the southern counties. Archbishop Cranmer presented him to the living of All-Hallows, but he declined it, and gave his reasons stoutly before the privy council, alleging that the reformed church of England still needed further reformation. King Edward, with the consent of the privy council, offered him a bishopric, which he also declined. King Edward died 6th July, 1553, and Knox waited in London till the accession of Mary on the 19th of the same month, when, after itinerating through Kent and Buckinghamshire, he returned to Newcastle. At this period he was married at Berwick to Marjory Bowes, a lady to whom he had been long and warmly attached. The reign of Mary was now unfolding its terrors in England; and obeying the 'voices of his brethren,' and rather against his own will, Knox left the kingdom, and landed at Dieppe in Normandy on the 20th January, 1554. He departed from Dieppe in February, 'whither God knoweth,' proceeding through France to Switzerland, and was cordially received by the leading divines of the Helvetic churches, between whom and many of the English reformers a correspondence had been kept up. At Geneva he won the friendship of Calvin; he applied himself to hard study, though he was close on fifty years of age, and according to Dr. M'Crie, made himself master of the Hebrew language. A congregation of English exiles at Frankfort having elected him as their pastor, he set out for that city, and immediately commenced his ministry. But the germs of dispute had been already sown on the question of surplice, litany, and order—the puritan controversy in miniature. The English litany was followed to a great extent; but Dr. Cox, who had been preceptor to Edward VI., came with other exiles to Frankfort, and raised immediate disturbance by declaring their resolution 'to do as they had done in England.' Meetings were held, keen controversy commenced, the faction of Cox accused Knox of treason; and though the magistrates of the city would not listen to the calumny, they advised him for the sake of peace to leave the city. Knox went again to Geneva, but his desire to visit Scotland, from which he had gleaned favourable tidings, so grew upon him that he recrossed the Channel in 1555, and journeyed at once to Berwick to his wife and household. He then went to Edinburgh and preached privately to many little audiences. Next he accompanied Erskine of Dun into Angus, where during a month's sojourn he preached every day; then he was for a season with Sir James Sandilands at Calder House, still urging on the work of reformation. Afterwards he visited the district of Kyle, the seat of the Scottish Lollards; returning to Angus, where the gentlemen professing the new faith formed and subscribed a bond or covenant for mutual defence and encouragement—probably the first instrument of the kind in Scotland. But his movements were at length discovered, and his preaching was vehemently denounced by the alarmed clergy. Knox was at once summoned to appear before a clerical convention, to be held in the church of the Blackfriars, Edinburgh. But his accusers, never imagining that he would attend, and being not wholly sure of the regent's support, wavered, and then conveniently finding some informality in the summons, resolved to set it aside. At

this crisis he wrote his well-known letter to the queen regent; and quiet, earnest, and void of all oburgation as it was, she threw it from her contemptuously, calling it 'a pasquil.' Word was now brought him that the English congregation at Geneva had chosen him one of their ministers, and he resolved to accede to their wishes. He left Scotland in July, 1556, his wife and family having preceded him; and having joined them at Dieppe he proceeded to Geneva, where he remained the two following years. No sooner was it known that he had left the kingdom, than the clergy who had deserted the diet against him met at Edinburgh, and passed the usual sentence of condemnation upon him; and because they had not his person to chain to the stake, they gratified their malice by causing him to be burnt in effigy at the cross. Against this sentence Knox wrote a sturdy 'Appellation,' which he sent over to the nobility and people of Scotland.

In the midst of his peaceful life in Geneva he received an invitation to return to Scotland. But at Dieppe he learned adverse tidings which sorely distressed him, and he sent a letter full of rebuke and sorrow to the nobility who had invited him. Knox went back to Geneva in 1558. At this epoch the English translation of the Old Testament was made, commonly called the Geneva Bible. Knox probably had a hand in it, along with Coverdale, Gilby, and others. Then and there, too, he published his 'First Blast of the Trumpet against the monstrous regiment of women,' a vehement defence of what is termed the Salique law, in reference at least to France, and which allows no female to reign. Meanwhile, changes favourable to the Reformation were taking place in Scotland; the Protestants had grown in numbers and influence. Persecution indeed broke out; electric clouds were gathering from all parts of the heavens; and as a resolute struggle was impending, Knox was invited over, and sailing from Dieppe on the 22nd of April, he landed at Leith on the 2nd of May, 1559.

No sooner was Knox's arrival known than, through the influence of the panic-stricken clergy, he was proclaimed an outlaw, in virtue of the former sentence pronounced against him. Going north to Dundee, he joined with the Protestants who had there assembled in great numbers and proceeded with them to Perth, where he thundered against image-worship and the idolatry of the mass. The discourse being finished and the audience quietly dispersing, a priest uncovered an ornate altar and prepared to celebrate mass. A boy uttered some words of juvenile disapprobation, and the priest struck him. The youth pitched a stone at his castigator, and it broke one of the images on the altar. The fracture of the image was as the spark that suddenly creates an explosion. The onlookers were roused, and without a moment's thought, rushed on altar and images and demolished them. The tumult grew as the mob maddened—religious houses were pulled down, and all pictures and images defaced. This demolition, so often misrepresented, Knox distinctly ascribes to the 'rascal multitude.' The queen regent looked on this riot as a serious rebellion, and mustered an army to quell it, but the Protestants, aware of her ultimate designs, levied a host in self-defence. An opportune treaty prevented any hostile conflict. The 'lords of the

congregation,' finding from various circumstances that the regent was not to be trusted, were alarmed into activity. Knox would not be silenced, and going to St. Andrews, he preached so effectively that the popish worship was peacefully abolished, and the churches stripped of what were held to be idols or idolatrous symbols. Other parts of the country imitated St. Andrews, but not so peacefully; many fine edifices were demolished, and many valuable works of art perished in the surge and fury of the popular revolution. When the army of the congregation with which Knox had been at Cupar Moor, where they lay face to face with the regent's forces, reached Edinburgh, the Reformer, who was still with them, preached on the day of their entrance in the church of St. Giles, and next day in the church of the Abbey. The inhabitants immediately met and elected him their minister, and Knox complying with the call commenced his labours in the city. On the approach of the regent's host Knox quitted Edinburgh, made an extensive tour through the country, and preached in many of the larger towns; 'men,' as he says, 'of all sorts and conditions obeying the truth.' During the negotiations for military assistance from England, Knox for a time conducted the greater part of the correspondence. These negotiations failed, and the party of the regent, on whom sentence of suspension had been passed by a convention, appeared for a season to triumph, and a price was set on the reformer's head. But his eloquence cheered the despondent reformers. Queen Elizabeth at length favoured their cause, and a treaty was concluded. The French troops were dismissed from Scotland, and the English regiments that had been sent down marched back. Parliament met—a confession of faith was speedily drawn up, and on the 24th of August, 1560, the papal jurisdiction was formally abolished, and all penal laws in its favour rescinded. A book of discipline was compiled, pastors, doctors, elders, and readers were appointed, and five superintendents were set over various provinces. The patrimony of the church was to be allotted to the ministry, schools, and the poor—a scheme of division soon frustrated by the court and the greed of the nobility and gentry. The first meeting of the General Assembly of the Protestant church of Scotland was held at Edinburgh on the 20th of December, 1560.

No sooner had Queen Mary arrived from France in August, 1561, than she had a long interview with the stern reformer, after a sermon which had galled her. She accused him of many things, and even of effecting his ends by magical arts. Knox had interviews with the queen on various occasions, but neither menace nor flattery could move him. Parliament met, but it had lost some of its earnest attachment to Protestantism. The preaching of Knox became more stormy and vehement; his tongue was felt to be a match for Mary's sceptre. The queen having heard that he had preached about her marriage, summoned him into her presence, and in her petulant censure of him burst into tears. A riot having taken place in the chapel at Holyrood, and Knox having sent a circular to several gentlemen to attend at the trial of the rioters, he fell under the royal displeasure, and was summoned before an extraordinary meeting of the council and nobility. This act on his part can only be justified on the plea of necessity—for it

virtually implies a species of double government, that is, anarchy. The queen would have him found guilty of treason, and could not but exult over one 'who had made her weep.' The nobility at once acquitted the reformer, and 'madam was disappointed of her purpose.' In March, 1564, Knox, who had been three years a widower, and was now on the verge of sixty, married Margaret Stewart, daughter of Lord Ochiltree—his lordship being a descendant of Robert, duke of Albany, second son of King Robert II. The union appears to have been a happy one. The marriage of the queen with Darnley soon followed. Knox's tongue gave no little scandal on the occasion, and he was ordered in 1565 to desist from preaching. A secret league was formed in France by the duke of Alva and Catherine de Medici to extirpate Protestantism, and the queen, at the instigation of her uncle the cardinal of Lorraine, had subscribed to it. These measures were counteracted, Rizzio was assassinated, and Knox withdrew from Edinburgh. Tytler's assertion, that Knox was 'precognisant of the intended murder,' rests on no sufficient proof. The murder of Darnley soon followed; Mary wedded Bothwell, and resigned the crown in favour of her son, appointing the earl of Moray regent during his minority. On the 29th July Knox preached the sermon in Stirling at the coronation of James VI. Under the regency of Moray harmony subsisted between the church and the court, and Knox carried out as far as he could his various plans for strengthening the Protestant interest, and securing a liberal income to the clergy. But the regent was shot in Linlithgow, and died 23rd January, 1570. The regent's death, and his numerous and pressing anxieties during that critical period, preyed upon Knox's health, and in October of the same year he was struck with apoplexy. In a few days he recovered his speech, and was able to preach again, but not with his wonted vigour. The death of the regent produced disastrous results, and through the weakness of Lennox his successor, the abilities of Maitland, and the defection of Kirkcaldy of Grange, the queen's party gained strength, and Knox was subjected to numberless annoyances. His life was often threatened, and an assassin fired into his house. He left Edinburgh, and took up his abode in St. Andrews, still carrying on by tongue, pen, and counsel the great work to which his life had been devoted. In January, 1572, a convention of the church met at Leith, and to save somewhat of the revenues of the church, agreed to set up a modified episcopacy. It was a compromise which Knox was too old and feeble to oppose, and he yielded to the necessity. During a cessation of arms he returned to Edinburgh, and denounced in glowing terms the massacre of St. Bartholomew, the news of which had recently arrived. Sickness again seized him; he paid his servants' wages—adding, it was the last they should receive from him. His session met in his chamber, and he delivered them a farewell charge. On Friday, the 21st, he desired his servant to order his coffin to be made, and he died on Monday, 24th November, 1572, in the sixty-seventh year of his age. Two days afterwards his body was interred in St. Giles. The funeral was attended by an immense concourse of people, weeping, and of the resident nobility; and as his body was laid in its last resting-place, the earl of Morton, who had been newly elected

to the regency, pronounced the well-known eulogy, 'Here lies he who never feared the face of man.' John Knox left five children, two sons by his first wife, and three daughters by his second wife. His sons were educated at St. John's College, Cambridge. Knox's life was a busy and uncertain one, yet he found time to write a 'History of the Reformation in Scotland.' Many additional tracts were published by him, as the times demanded, and many letters and exhortations are still extant. The Reformer was rather small in stature, and wore a beard which reached almost down to his girdle. (*Life* by Dr. M'Crie.)

KNUTSFORD. [CHESHIRE.]

KOALA (*Phascogaleos cinereus*), a marsupial animal belonging to the family *Phalangistidae*, or Phalangiers. It is a native of New South Wales, about two feet long and covered with a gray fur. On the ears are tufts of long hair. It is a nocturnal animal, lives in trees, and feeds on their tender shoots. The Mahrattas apply the same name to the jackal.

KOBRE'SIA, a genus of plants belonging to the natural order *Cyperaceæ*. There is only one species of this genus, *K. caricina*, which is found throughout Europe, and in Great Britain on moors in Yorkshire, Durham, and Perthshire.

KOELE'RIA, a genus of plants belonging to the natural order *Gramineæ*. There is only one British species of this genus, *K. cristata*.

KOENIG, FRIEDRICH, one of the inventors of the first practically successful printing machine, was born at Eisleben on the 17th of April, 1775, and died at Oberzell on the 17th January, 1833. He became a printer, and worked in that capacity till 1797. He then established a printing office in his native town, and for years laboured to invent a method of printing by machinery, and had, in conjunction with his friend and coadjutor Bauer, devised a project for that purpose about 1806, but was baffled in his attempts to carry it into execution by the difficulty of finding any capitalist able and willing to pay the expense. Having at length visited England in pursuit of this object, he was furnished with the necessary funds by the well-known printers, Bensley, Woodfall, and Richard Taylor. The first patent of Koenig and Bauer was obtained in 1810, for a machine in which the paper was pressed against the type by a flat platen, as in the common printing press. Their most important patent was that of 1811, for a machine in which the paper was pressed against the types by a revolving cylinder. This machine may be considered the parent of all the successful printing machines which have since been invented, for though they have been improved in many respects, its essential principle is found in them all. In 1814 occurred one of the most remarkable events in the history of printing: a machine on the principle of Koenig's invention, of unprecedented size and power, was erected by the proprietors of the *Times*, the number of which for the 14th of November of that year was the first newspaper printed by steam-power. From that time the art of machine printing made rapid progress, and has of late years attained an enormous extension. Koenig and Bauer subsequently established a manufactory of steam printing presses at Oberzell, near Würzburg, in Bavaria. It is gratifying to know that this undertaking succeeded, and that the in-

ventors of the printing machine were rewarded by a prosperity which rarely falls to the lot of the greatest benefactors of mankind.

KOETHEN. [ANHALT.]

KOH-I-NOOR (Mountain of Light), the name of the large diamond obtained by Queen Victoria from Maharajah Dhuleep Singh, the ruler of the Punjab, on the annexation of that country to British India in 1849. It is said to have originally weighed 900 carats, but being badly cut it was reduced to 279 carats. It was still further reduced, by recutting, to 186 carats, and was thus shown in the Great Exhibition of 1851. In 1852 it was once more recut, and now weighs about 123 carats. Its present value is estimated at 120,664*l*. The last process of recutting was performed by M. Coster, of Amsterdam, in the employ of Messrs. Garrard, and occupied several weeks, on account of the extreme precautions necessary in dealing with a gem of such enormous value. [LAPIDARY WORK.]

KOLA. [ARCHANGEL.]

KOLA NUTS, *Kola, Cola, Cura, or Curo*, the seeds of the *Cola acuminata*, are made use of as food and medicine by the natives of West Central Africa. Their value seems due to the presence in them of about two per cent. of *theine*, a substance which also exists in tea, coffee, and maté. If eaten in large quantities they produce wakefulness.

KOLAPOOR. [COLAPOOR.]

KOLLIN. [COLLIN.]

KOMORN, or COMORN, a royal free town of Hungary, on the left bank of the Danube, 48 miles N.N.W. of Buda. It is a steam-packet station, and has an active trade in corn, wine, wood, and fish. The celebrated wine called Monostor grows in its neighbourhood. The town is fortified, and its citadel, constructed by Corvinus, and extended in 1805, is considered one of the strongest in Europe. It was long unsuccessfully besieged by the Austrians in 1849, and only surrendered on honourable terms when the struggle had ceased elsewhere. In the town the inhabitants, who are mostly Protestants, number altogether 12,160. It stands at the mouth of the Waag.

KONG MOUNTAINS. Between 9° and 10° N. lat., and 9° and 10° W. long., there exists a high mountain knot, in which the Joliba, Quorra, or Niger, the Gambia, the Rokelle, and the upper feeders of the Senegal take their rise. From this same plateau one mountain range runs N.E., forming the watershed between the basins of the Niger and the Senegal; another takes a north-western direction, dividing the feeders of the Senegal from those of the Gambia; while a third range runs nearly E. along the parallel of 9° N. lat., to the northward of the territories of the Mandingoes, the Foolaahs, and the Ashantees. To this last range the name of the Kong mountains has been given, from the word *kong*, which in the dialect of the Mandingoes is said by Park to mean a mountain. In the kingdom of Yarriba the range is said to turn S.E., and to terminate on the banks of the Niger, near the confluence of the Tehadda with that river. But of this range, if it forms one continuous mass, very little is known. Nothing definite has been ascertained regarding its length, width, or height, though it is said many of its peaks reach the snow line. [SENEGAMBIA.]

KONIGA, a genus of plants of the order of *Cruciferae*. The flowers are white and sweet scented.

KÖNIGGRÄTZ, a village in Bohemia, near which was fought the famous battle of Sadowa, between the Prussians and Austrians, July 3, 1866. [SADOWA.]

KÖNIGSBERG, one of the two governments into which the province of East Prussia is divided, extends along the Baltic from the Gulf of Danzig to the frontiers of Russia, and is bounded S. by the government of Gumbinnen and by Polish Prussia. The area is 8636 square miles, and the population in 1868 was 1,067,313. The coast is low and indented by two extensive shallow fresh-water bays, which communicate with the Baltic each by a narrow strait towards its eastern extremity. One of these is called the *Curische-Haff*. The other, called the *Frische-Haff*, extends for 57 miles in a south-west direction from Königsberg, with an average breadth of 5 miles. The Gatt, or strait, by which it joins the Gulf of Danzig at Pillau, has 12 feet depth of water, and is in breadth 3000 feet. In all the rest of its length it is separated from the Baltic by the *Frische-Nehrung*, a narrow tongue of land, consisting chiefly of sandbanks. The water in the Haff is shallow, in no place more than 12 feet, especially in summer, so that no large vessels can navigate it. Several arms of the *Vistula*, the *Passarge*, which is navigable, and many other rivers, fall into the *Frische-Haff*. The surface of the government is a flat agricultural country, with some extensive forests. Wheat, rye, flax, hemp, &c., are the chief products. Cattle and sheep are numerous.

The chief town of the government of Königsberg is **KÖNIGSBERG**. *Memel*, the most northern town in Prussia, is situated at the mouth of the *Dange*, and on the eastern side of the strait that joins the *Curische-Haff* to the Baltic, 74 miles N.N.E. of Königsberg. It is well built, and has a safe harbour defended by a citadel and by a strong fort on the south side, the construction of which was completed in 1868. The entrance to the harbour is crossed by a bar, on which there is from 13 to 18 feet of water, so that it can be entered at nearly all seasons by vessels drawing about 17 feet, and an unlimited number of ships can lie in it with perfect safety. It is, indeed, one of the best harbours in the Baltic, and its communication with the sea is never impeded by ice, even in winter. The town is well situated for commerce, and has a large trade with the interior of Prussia; also with Russia, Great Britain, Holland, Belgium, Denmark, Bremen, Hanover, and Norway. The number of ships which entered the port in 1867 was 980 (228,716 tons), and the clearances 968 (210,700 tons). Value of the imports, 318,195*l.*; the principal articles being coal, herrings, salt, spirits, and sugar. The exports amounted to 861,178*l.*, of which two-thirds were destined for Great Britain. Timber constituted more than one-half, and corn, flax, hemp, hides, and rags the remainder. There is a lighthouse 128 feet high in front of the harbour, and in the town are several breweries, distilleries, woollen and soap factories, oil and saw mills, &c. In consequence of a fire in 1854, the town has undergone almost a complete renovation, and is now clean and well built. It was inclosed by walls in the time of the Teutonic knights, and has Lutheran, Calvinistic, and Roman Catholic churches, a Jews' synagogue, arsenal, ex-

change, theatre, high schools, hospital, &c. There are large docks in which shipbuilding is extensively carried on, and for which the town has long been noted. The population in 1861 was 17,596. *Braunsberg*, a busy commercial town on the *Passarge*, and near the entrance of that river into the *Frische-Haff*, has a population of 9000, who manufacture cloth, leather, and yarn, and export corn and timber.

The other government of East Prussia, *Gumbinnen*, lies S.E. and S. of the government of Königsberg. It has an area of 6310 square miles, and its population in 1868 was 743,783. The surface of Gumbinnen, like that of Königsberg, is flat, except in the south, where a large portion of the surface is hilly, and abounds with lakes. The produce is similar to that of the government of Königsberg. The largest horses in Prussia are bred in the government of Gumbinnen. The chief rivers are the *Memel* [*NIE-MEN*], which passes *Tilsit*, and flows by several arms into the *Curische-Haff*; and the *Pregel*, which flows due west, and falls into the *Frische-Haff* below Königsberg. [PRUSSIA.]

In the government of Gumbinnen the most important town, *Tilsit*, is situated on the left bank of the *Memel*, at the point where the *Tilse* falls into that river, which is here crossed by a bridge of boats, 60 miles N.E. of Königsberg. It is a pretty, well-built town, and contains five churches, a fine town-hall, a gymnasium, very extensive barracks, two hospitals, and 16,146 inhabitants, including the garrison. The townspeople trade in corn, linseed, timber, beer, spirits, leather, &c. There are manufactures of woollen cloth, hosiery, arms, and hardware; hemp and flax are also exported. The town is defended by a strong castle. *Tilsit* has acquired celebrity by being the place where the famous treaties were concluded between France, and Russia, and Prussia, on the 7th and 9th of July, 1807. *Interburg*, a town of 10,900 inhabitants, stands near the junction of the *Pregel* and the *Instar*, on the left bank of the *Angeper*. It has manufactures of cloth, linen, woollen stockings, leather, and spirits, and trades extensively in corn and flax. There are Lutheran and Calvinistic churches, a normal school, and several breeding studs. *Gumbinnen*, the chief town of the government, stands on the *Pissa*, a few miles E. of *Interburg*, and has 6800 inhabitants. The town is regularly built, and has woollen and linen factories, distilleries, breweries, a good trade in corn, and a gymnasium, two hospitals, public library, and schools of architecture and midwifery. The inhabitants are mostly all Protestants.

KÖNIGSBERG, the capital of East Prussia, is situated near the mouth of the *Pregel*, 78 miles E. by N. from Danzig, in 54° 42' N. lat., 20° 29' E. long., and had in 1861 87,072 civil and 7487 military inhabitants. In 1865 the total number was estimated at 102,000. It consists of three parts, called the Old Town, *Löbenicht*, and the *Kneiphof*, besides the royal palace and the citadel *Fredericksberg*, and fourteen suburbs. The Old Town and *Löbenicht* are on the north side of the river; the *Kneiphof* stands on an island formed by the *Pregel*. The origin of the city dates from 1255, when the Teutonic knights built a fortress on the height where the castle now stands. After 1365 it became one of the principal cities of the Hanseatic League; and here, in 1701,

Frederick III. of Brandenburg was crowned the first king of Prussia. In 1855 it celebrated the completion of the sixth century of its existence.

The town is irregularly built, and the streets are generally narrow and crooked; but during the last few years some better edifices have been erected. The Pregel is crossed by seven bridges. The most remarkable buildings are the castle or royal palace, and the cathedral, in the library attached to which are several autograph letters of Luther to Catherine Bora. Among the numerous public institutions is the university, founded in 1544, with which are combined two theological seminaries, one Polish and one Lithuanian, a library of 160,000 volumes, a botanic garden, and an observatory. There are likewise an exchange, town-house, citadel, and theatre, three gymnasia, school of arts and architecture, deaf-mute and blind asylums, and many other charitable institutions. Königsberg has communication by the Friedrichs-Gruben Canal with the Memel, by which river, the Oginski Canal, and the Dnieper, it has the advantage of a complete interior navigation into Poland, Lithuania, and even to the Black Sea. The port of Königsberg is Pillau [PILLAU], where vessels that cannot take all their cargo from the warehouses of Königsberg ship the remainder of their freight, which is brought from the Pregel to Pillau in lighters from 20 to 100 tons burthen. The manufactures consist of woollen cloth, linen, cotton, silk, leather, tobacco, sugar, soap, starch, sealing-wax, beer, and spirits. The exports are composed of corn, flax-seed, flax, hemp, oil cakes, feathers, rags, hair, wood, zinc, iron, and hides, and were valued in 1867 at 7,320,922*l.*, of which 1,877,185*l.* were for goods forwarded to foreign countries by sea, and the remainder to other Prussian ports and to Russia. The export trade in grain is very extensive, and there are some shipbuilding yards. The imports are chiefly sugar, coffee, spices, dyewoods, tobacco, salt, various raw materials, and manufactured goods, the total value amounting to 7,192,725*l.* One-half of the sea-trade is with Great Britain. The number of vessels which entered the port of Pillau in 1867 was 1603 (167,000 tons), of which one-third was British. The regulation of harbour affairs for Pillau and Königsberg, which was formerly in the hands of the corporation of merchants at Königsberg, was by mutual agreement given up to the state in 1864. The Prussian government has since built strong forts to protect the harbour, and executed works of great magnitude for the greater convenience and safety of vessels. A railway from Königsberg to Pillau was opened in 1867, and extended to Rassenberg and Lyck in 1868. It is being carried on to a point on the Petersburg and Warsaw Railway, and will thus have the advantage of a carrying trade between the west of Europe on the one side, and Poland and Russia on the other.

KODDOO (*Strepsiceros kudu*), an exceedingly beautiful African antelope. It is of a brownish-gray colour, and its sides are marked by from seven to ten white stripes. The horns are long and twisted. It is about 3½ feet high at the shoulder, and not more than 4½ feet long. The flesh of the koodoo is much valued by the natives.

KOORDISTAN. [KURDISTAN.]

KOORIA MOORIA or CURIA MURIA ISLANDS, a group of six islands distant about 20

miles from the south-east coast of Arabia, in lat. 17° 33' N., long. 56° 6' E. They were ceded to Great Britain in 1854. Hellaneeyah, the largest, is inhabited by a few fishermen; the others are very desolate and sterile. Large quantities of guano have, however, been procured from here. In 1858 the value of the exports of this article was 81,877*l.*, which gradually decreased, till, in 1861, they stopped entirely.

KOPECK, a Russian coin, about the value of a halfpenny.

KORAN. [MOHAMMED.]

KORDOFAN, or KORDUFAN, a country lying to the south of Nubia, in Central Africa, formerly a dependency of Sennar, since 1820 a province of Egypt, between lat. 12° 21' and 15° 18' N., long. 24° 34' to 27° 37' E. The Bahr-el-Abiad (White Nile) traverses the south-eastern part of the country, which consists of an assemblage of several small oases, divided from Dar-Fur by vast deserts. The population is composed chiefly of negroes, who devote themselves to agriculture. The rest of the inhabitants are settlers from Dongola, who are merchants, and frequent the caravan routes, and Arabs, who in general wander from place to place in the deserts. Gold dust and iron ore are found; the latter is worked. On the oases the principal objects of cultivation are millet, sesamum, and some wheat and barley. The soil is peculiarly adapted to the cultivation of the first article, which is the staple food of the country. The wealth of the Arab tribes consists of their horses, cattle, and camels, which latter are lent on hire. The negroes rear great numbers of cattle, sheep, and goats. Among the wild animals are elephants, giraffes, and antelopes. This district was first made known in Europe by Browne. Slavery was abolished in 1857. Obeid, formerly a considerable town, was, on the occupation of the Egyptian Turks, almost destroyed. It now consists of several villages of mud houses, covered with straw, clustered together in an oasis, and is said to contain 20,000 inhabitants. It has a considerable trade.

KÖRNER, THEODOR, was born at Dresden in the year 1791, of respectable parents. The weakness of his health prevented any great application to study; but as he grew, both his mind and body gained strength, and he showed an early inclination to history, mathematics, and physical science. He went to the universities of Leipzig, Berlin, and Vienna, where he laboured much at poetical composition. Two pieces, 'Die Brant' (The Bride), and 'Der Grüne Domino' (The Green Domino), were acted at Vienna in 1812, and meeting with success were followed by others, of which 'Zriny' and 'Rosamunde' (the English Fair Rosamond), two tragedies, were works aiming at a high character.

The events of the year 1813 made a deep impression on Körner. Inspired by patriotic zeal he joined a volunteer corps in the cause of Prussia against the French. He was wounded by two sabre cuts at the battle of Kitzén, and in a subsequent battle, August 28, he was killed by a shot, and buried by his comrades at the foot of an oak on the road from Lübelow to Dreikrug.

As Körner was scarcely twenty-two years of age at the time of his death, his works, which are rather numerous, must be judged with lenity. His fame chiefly rests on a collection of lyrical pieces called

'Leier und Schwert' (Lyre and Sword), many of which were written in the camp. His happiest effort of imagination is the 'Schwert Lied' (Sword Song), in which the sword becomes a person and addresses its owner—a piece which has been translated (not very closely) by Lord F. L. Gower.

A complete edition of his works, in one volume, was published at Berlin in 1835.

KOSCIUSKO, THADDEUS, born in 1756, of a noble family of Lithuania, after studying at Warsaw and Paris, was made a captain in the Polish army. He afterwards accompanied La Fayette to assist the revolted American colonies against England. He obtained the rank of general officer in the American army, with a pension. In 1789 he was made major-general in the Polish army. He served with distinction in 1792 against the Russians, but King Stanislaus having submitted to the empress, and Poland being occupied by Russian troops, Kosciuszko with several other officers left the service, and withdrew to Germany. When the revolution broke out in Poland at the beginning of 1794, Kosciuszko was put at the head of the national forces. After some temporary successes he was overpowered by superior numbers at the battle of Macziewicz, October 10, 1794, and taken prisoner. He was conveyed to St. Petersburg; but being released by the Emperor Paul, he repaired to America, and returned to France about 1798, where he refused all offers of employment from Napoleon, and exerted himself to procure an extension of the new kingdom of Poland, founded in 1815.

In 1816 Kosciuszko settled at Soleure, in Switzerland, and energetically applied himself to agricultural pursuits. He died 15th October, 1817, in consequence of a fall from his horse. His remains were removed to Cracow, and placed in the vaults of the kings of Poland.

KOSTROMA. [COSTROMA.]

KOTBUS. [BRANDENBURG.]

KOTZEBUE, AUGUST FRIEDRICH FERDINAND VON, was born at Weimar in 1761. He studied at the gymnasium of that town, and also at the University of Jena. His poetical and dramatic tastes had manifested themselves at an early age. He studied the law, but at the same time composed slight theatrical pieces. In 1781 he went to St. Petersburg, and was kindly received by the emperor of Russia, who raised him to the rank of nobility, and made him president of the government of Esthonia. While at Revel he wrote several favourite works, and among them 'Menschenhass und Reue,' (Misanthropy and Repentance), well known in this country under the title of 'The Stranger.' He travelled in 1790 to Pyrmont, visited Paris, and returned to Esthonia in 1795, where he wrote above twenty dramas. In 1798 he went to Vienna as poet to the Court Theatre, but gave up that place in two years, and received a yearly pension of 1000 crowns. He returned to Russia, where he had scarcely arrived when he was arrested and sent to Siberia. A translation made by a young Russian of a paltry little piece by Kotzebue, called 'Der Leibkutscher Peters des Grossen' (The Body-Coachman of Peter the Great), so delighted the Emperor Paul that he was recalled from banishment. After the death of this emperor he went to Weimar, and thence to Jena. Some disagreement with Goethe caused him to remove to

Berlin, where he edited one or two periodical works. The events of 1806 caused him to fly to Russia, where in his writings he unceasingly attacked the Emperor Napoleon and the French. In 1817, after having again visited St. Petersburg, he was despatched to Germany by the emperor of Russia (Alexander), with a large salary, to watch the state of literature and public opinion, and to communicate all that he could learn. He edited a weekly literary paper; but the German people became disgusted with his scoffing at liberal opinions, and his conduct particularly roused the indignation of Sand, a student and political enthusiast, who, considering him an enemy to liberty, assassinated him on the 23rd of March, 1819.

Kotzebue's fame rests almost entirely on his dramas, which are nearly 100 in number, and of the most various degrees of merit. Many of them have been translated into English. We need only mention 'The Stranger,' 'Lovers' Vows,' and 'Pizarro.'

KOURSK. [KURSK.]

KOW-LOON, a suburb of Hong-Kong, on the mainland of China, ceded to the British in January, 1861. The area is only a few square miles, the place being reserved as a sanitarium for troops and for the villa residences of the colonists.

KOWRIE PINE (*Dammara Australis*), a beautiful pine of New Zealand. It sometimes attains a height of 130 feet. The wood is white and close grained. The gum known as Australian copal is obtained from a species of kowrie pine.

KRAAL. In the southern part of Africa, among the Hottentots, a collection of huts.

KRAKEN (German), a name applied to a fabulous ocean monster or sea-serpent of enormous size. No satisfactory proof of its actual existence has ever been adduced.

KRAMERIA/CEÆ, a small natural order of poly-petalous exogenous plants, by most botanists referred to *Polygalaceæ*, but apparently distinct. *Krameria triandria*, or *Rhatany*, is a small low-lying under-shrub, growing on the dry projecting parts of the mountains of Peru near Huanaco, &c. The root is heavy, and devoid of odour; but the taste, especially of the bark, is strongly astringent and bitter, yet not disagreeable. Iodine turns it black. According to the analysis of Gmelin, it contains much tannin, with saccharine and mucilaginous matter, woody fibre, and salts.

KREASOTE. [CREASOTE.]

KREFELD. [CREFELD.]

KREMNITZ. [CREMNITZ.]

KREUTZER, a small copper coin of Germany, of different values in different states. In some places thirty kreutzers are equivalent to 1s. But in Frankfurt, and in the southern parts of Germany, three kreutzers are equal to 1d. sterling. In the canton of Berne, the coin passes for six deniers, and in Bale for five. The Austrian paper currency, marked zechn (ten) kreutzers, passes for twelve.

KRISHNA. [VISHNU.]

KROKIDOLITE (Gr. *kroke*, 'woof,' and *lithos*, 'a stone'), a mineral so called from its resembling asbestos, and having elastic fibres. It is massive and opaque, and of a light-blue colour. Its specific gravity is 3.2; and its constituents are silica, protoxide of iron, soda, magnesia, and lime.

KRUMAN. [BETCHOUANA.]

KUBAN, or KOOBAN, a Russian river that rises in Mount Elbrouz, the highest peak of the Caucasian mountains, and flows in a general N.W. direction between high mountain ranges, from which it receives numerous feeders, until it reaches the level country E. of the Sea of Azof. It here turns westward, and continues in that direction for the rest of its course. Towards its mouth it enters a low flat country, and along its banks salt marshes extend to a considerable distance. In this plain the river divides into two branches, and forms the Island of Taman. One arm of this river falls into the Sea of Azof; the other falls into the Kubanskoi Liman, or Lake of Kuban, which is united by a narrow passage to the Black Sea. The Kuban is about 400 miles in length, and generally runs with a rapid current, rendering it difficult of navigation, though barges come up to Yekaterinodar. Along the banks of this river are numerous Russian forts.

KUBLA KHAN, or KHUBILAI KHAN, the grand khan or khagan of the Mongols, and emperor of China, first appears in history as the conqueror of the north of China in the year 1260. He was a learned and enlightened monarch, and endeared himself to the Chinese by his attention to the men of letters, and by the respect he paid to the memory of their former renowned monarchs. In 1280 he finally extinguished the Sung dynasty, invading and subduing southern China, and founding a new government, which, however, only lasted eighty years. After the Mongolian conquest of China, Kubla's dominions extended from the Arctic Ocean to the Chinese Sea, and from the Corea to Asia Minor, being the largest territory ever governed by any one monarch. His court was attended by the learned men of India, Persia, and some even from Europe, notably the renowned Marco Polo. Kubla died at Peking in 1294.

KUGLER, FRANZ THEODOR, Professor of the History of Art in the Royal Academy of Berlin, and distinguished for numerous works on the history of art, was born at Stettin in 1808. His principal work was his 'Handbook of the History of Painting, from the age of Constantine to the present time.' It has been translated into the principal languages of Europe. He died in 1858.

KUJIE, the ancient Arabic characters; so called from Kujia, a town on the Euphrates. Their study has recently attracted the special attention of Oriental scholars.

KUMAON, a district forming part of the British territory in Northern Hindustan, presidency of Bengal, comprehending an area of about 7000 square miles, includes the country between the sources of the Ganges and the river Kalee, extending as far south as 29° 20' N. lat. The whole of this district presents a succession of mountainous ridges, increasing in elevation as they approach the north, until they reach the snowy peaks of the Himalayas. Towards the south the country presents an almost uninterrupted succession of forests, containing many large trees; but in the higher region to the north, where the height amounts to 2500 feet above the plains, tropical productions disappear, there are no longer forests of any description, but in their place numerous groups of trees of various kinds commonly found

in Europe; among these are the oak, fir, willow, mulberry, and birch. The country was acquired by the British in 1815, to whom it offers little advantage, except from its climate, which is found to be almost as efficient in restoring tone to the constitution of Europeans as a visit to Europe. For this purpose the capital, Almora, is much frequented. [ALMORA.] The population is estimated at 166,755. Wheat, hemp, rice, and a little corn are raised in the higher plains, and the cultivation of the tea plant has lately been introduced with a fair amount of success. The mineral products comprise gold, copper, and lead, which, with ginger, turmeric, &c., are sent to the lowlands, and exchanged for chintz and cotton cloths, tobacco, sugar-candy, glass, hardwares, and European manufactures. Some coarse woollen, hempen, cotton, and camlet fabrics are woven, and an active transit trade is carried on between Tibet and Hindustan. The district of Kumaon contains many Hindu temples and places of pilgrimage. The marsh land in the south part of the territory is unhealthy from the middle of March to the beginning of October, during which period it is deserted by strangers and natives.

KUNDUZ. [TURKISTAN.]

KUPFER SCHIEFER (Germ.), the copper slate of Thuringia, in which the remains of reptiles, especially saurians, have been found. This is the earliest instance yet noticed of the occurrence of oviparous quadrupeds in the history of the earth's crust. These reptiles were first discovered in the time of Leibnitz, and have been classed by Cuvier among the living Monitors.

KUR. [ARAS; GEORGIA.]

KURDISTAN (the country of the Kurds) comprehends the larger portion of that mountain region which divides the elevated table-land of Iran (Persia) from the low plains of Mesopotamia or Al-Jezireh. As it does not constitute a political division, its boundaries are not exactly determined; but the latitudes vary between 34° and 38° N., while the width of this mountain region may be about a hundred miles. About three-fourths are under the dominion of the Turkish sultan. The remainder belongs to Persia.

The mountain ranges, with which the country is almost covered, and which in some cases rise to a height of 13,000 feet, divide the surface into fertile valleys and extensive table-lands.

The largest river of Kurdistan is the Zab Ala, or Great Zab. It rises within the boundary of Persia, at an elevation of about 7000 feet above the sea-level, receives by its numerous affluents the drainage of almost the whole of Northern Kurdistan, enters Southern Kurdistan by a narrow glen, and joins the Tigris about 30 miles below Mosul. At the place of their confluence the rivers are nearly equal in size. The other large rivers of Kurdistan are the Zab Asfal, or Lesser Zab, and the Diyálah. They rise in the elevated region dividing Southern Kurdistan from the table-land of Iran, and after draining the first-mentioned country, they fall into the Tigris.

A sultry and vehement east wind, resembling the sirocco, is the terror of the country. The soil is generally parched in summer, but verdant during the wet season.

Suleimaniyeh, the modern capital of Southern

Kurdistan, and the residence of the hereditary pasha or wali, was built in 1788, and contains more than 2000 houses and about 10,000 inhabitants, six caravanserais, several baths, and five mosques. The commerce with the adjacent countries is considerable, and is concentrated in this place, the vicinity of which is famed for its breed of horses.

The fields of Kurdistan produce wheat, barley, and Indian corn; millet and rice are grown only in the lower districts towards the banks of the Tigris. Tobacco and cotton are largely cultivated, and supply articles of commerce. Fruits of various kinds are grown, but the only cultivated ground is near the villages. The country also yields the remarkable vegetable substance known as manna, but called in Turkish 'the Divine Sweetmeat.' It is found on the leaves of the dwarf oak, the flowering ash, and other plants. The Kurds go out before sunrise, after rainy or dewy nights, to collect it, spreading cloths under the trees, and shaking down the manna from the branches. The castor oil shrub abounds near the Tigris, and the slopes of the hills are covered with different kinds of oaks, some of which furnish the finest nut galls of commerce.

Sheep, cattle, and horses abound. A great trade is carried on in the latter with Turkey and Persia; the Kurdish breed being so famed for its spirit and endurance as to be almost exclusively employed in the Turkish and Persian cavalry. There are bears, wild hogs, wild goats, antelopes, jackals, and land-turtles. Bees are abundant.

Minerals are scarce, except building-stone. In the mountain region iron and sulphur are met with. There are several salt springs, and also springs which yield naphtha and petroleum.

As the passes through the ranges of mountains and hills are difficult, and single travellers are subject to be robbed and murdered, commerce is carried on by caravans. At least one caravan departs every month from Suleimaniyeh for the Persian towns of Tabriz and Hamadan. There are other caravans to Hamadan for goods from Bagdad, to Mosul for goods from Damascus, and to Erzerum for goods from the Black Sea.

The population of Turkish Kurdistan is estimated at about two millions, of which four-fifths are Kurds, and the remainder Armenians, Persians, Jews, and Turks. The Kurds are a stout race of men, of dark complexion, with black hair, a large mouth, small eyes, and a savage look. Their language is derived from the same stock as that of the modern Persian; but not having been fixed by writing, it has degenerated, and is divided into many dialects. In Turkish Kurdistan the nation is composed of two castes, the warriors, and the working people or agriculturists. The Kurds are Mohammedans.

The Kurds were known to the ancients. When subject to the kings of ancient Persia, they belonged partly to the province of Assyria, and partly to Media. After the time of Alexander their country was united to the kingdom of Syria, but was dismembered from it in the third century before Christ by the Parthians. It afterwards became a part of the new Persian empire, and fell with it under the dominion of the caliphs of Bagdad. After the destruction of the caliphate, Kurdistan partook of the numerous revolutions in Persia and Mesopotamia. The famous

Sultan Saladin was a Kurd, and appears to have got possession at least of a part of the country. But it soon passed under the dominion of the Mongols (1258), and finally (1388) was conquered by Timur. After the establishment of the Soofî dynasty (1502), Kurdistan constituted a part of Persia, and remained so till the seventeenth century, when the Kurds, oppressed by the Persians, revolted, and submitted themselves to the dominion of the Turkish emperor.

(Rich, *Narrative of a Residence in Kurdistan*; Ainsworth and Sheil, in *London Geographical Journal*; Ainsworth, *Travels and Researches in Asia Minor*, &c.; Rawlinson, *Journey from Tabriz through Persian Kurdistan*, &c.)

KURILE ISLES, a series of twenty-five islands extending between Kamchatka and the Japanese island of Jesso. They are all of volcanic origin, consisting of high masses of lava. Ten active volcanoes are known to exist on the nineteen northern islands. The vegetation is scanty, and on those near Kamchatka trees do not grow; but the southern islands are more fertile, especially Kunashir and Iturup, on which the Japanese have settled. The remainder are claimed by the Russians. The number of inhabitants are about 1200, who live mostly by hunting and fishing, the products of which they barter to Russian, American, Japanese, and Dutch traders. There are large quantities of beavers in the islands.

KURRACHEE is the principal seaport town of Seinde, on an islet of the Indian Ocean, in lat. 24° 51' N., long. 67° 2' E. The population in the town and suburbs is about 30,000. It stands on a low sandy shore, and formerly consisted, with its extensive suburbs, mostly of straggling huts; but it has been almost rebuilt, and greatly improved since it came into the possession of the British; and its trade and consequence are rapidly augmenting. The harbour, which has been deepened and extended, is sheltered by Point Munorah, about 4 miles to the south-west, on which is a fort, and beyond it a roadstead. Kurrachee was bombarded and taken by the English in 1839. A railway to Kotree, opposite Hyderabad (105 miles), was opened in 1861; and from thence the traffic is extended to Mooltan and other cities in the Punjab by means of steamers. In 1864 telegraphic communication was established with Calcutta, and with Europe by the Persian Gulf in 1865. The town has large warehouses, banking establishments, and all the requisites for a vast commercial emporium; and a regular steam communication exists with Europe and India.

KURRICHAHE. [BETCHOUANA.]

KURSK, or KOURSK, a government of European Russia, lying between 50° 10' and 52° 26' N. lat., 33° 40' and 38° 20' E. long., is bounded N. by Orel, E. by Voronetz, S. and W. by Kharkov and Tschernigov. Its area is 17,433 square miles, and the population 1,811,972. The surface of the province is undulating. It contains no mountains, but is traversed by many small eminences. There are no navigable rivers or large lakes, nor are the forests extensive. The east and south parts of the government belong to the basin of the Don, and are drained by numerous small streams that fall into the Donetz; the western and northern parts are drained by the rivers that form the Seim, a feeder of the Desna, which falls into the Dnieper. Kursk is one of the

most fertile provinces of the empire; the soil is so rich that it needs no manure; but the system of agriculture is very rude. The chief products are rye, wheat, barley, oats, peas, buckwheat, millet, poppy, hemp, hops, tobacco, and flax. Corn, of which there is always a large surplus for exportation, is sometimes kept in caves or pits for five, six, or even ten years. Horticulture is very general and successful; apples, cherries, plums, pears, hazel nuts, and melons are grown. Fuel is scarce; straw and dried cowdung are used as substitutes for firewood. The breeding of oxen, horses, and sheep is carried on very extensively, and the inhabitants keep great numbers of swine, domestic poultry, and bees. The minerals are iron, limestone, flints, and saltpetre. The manufactures comprise coarse woollens, leather, tallow, soap, saltpetre, and pottery. The exports consist chiefly of the natural productions of the country.

Koursk, the capital of the government, a town of 27,000 inhabitants, situated on the right bank of the Seim, 290 miles S.S.W. of Moscow, in $51^{\circ} 43' 30''$ N. lat., $36^{\circ} 27' 45''$ E. long., is the residence of the military governor of Koursk and Orel, and of the bishops of Koursk and Belgorod. The town is surrounded with palisades, the old ramparts having been converted into walks and gardens. The streets are narrow and crooked. There are sixteen churches, two convents, an ecclesiastical seminary, a gymnasium, hospital, several manufactories of leather, wax, and tallow, and an active commerce. It is the see of a Greek eparchy. A large annual fair is held near here in July, when goods are sold to the value of 1,000,000*l*. The other towns are—*BELGOROD*: *Karotcha*, on the left bank of a river of the same name in the south of the province, which has six churches, saltpetre factories, and 11,000 inhabitants; *Putiwl*, on the Seim, in the west of the province; population, 9000; it is well built, and though mostly of wood, has some good public edifices, churches, and charitable institutions, and brick-kilns: *Sudscha*, 50 miles S.W. from Koursk; population, 3000.

KÜSTRIN. [BRANDENBURG.]

KUTAIS. [GEORGIA.]

KUTCH, or CUTCH. [HINDUSTAN.]

KUTCH, or CUTCH (GUNDAVA), a province of Beloochistan, between lat. $27^{\circ} 40'$ and $29^{\circ} 50'$ N., long. $67^{\circ} 21'$ and $69^{\circ} 15'$ E.; bounded by Afghanistan, Scinde, and the provinces of Sarawan and Jhalawan. The length is 160 miles; the breadth, 130 miles; and the area 10,000 square miles. The population is supposed to be 100,000. The surface is low, and generally level, but ill watered, and destitute of forest land. The climate is oppressively hot. Where irrigated, the soil yields grain, pulse, cotton, sugar, madder, and fruits; and this is the most valuable part of the Khan of Kelat's

dominions. The country has also some commercial importance, from being traversed by the principal routes from Scinde to Afghanistan. The chief towns are Gundava, Dadur, Bhag, Lehee, and Kotree. (Johnston's *Dictionary of Geography*, 1864.)

KUYP, or CUYP, ALBERT, the son and disciple of Jacob Gerutze Kuyp, a landscape painter of Dort, was born at Dort in 1606. Scarcely anything is known of the circumstances of his life, except that he was a rigid Calvinist, of retired habits. The date of his death is not known. Kuyp is a great favourite in England, and it is here that his finest works are found. He has been called the Dutch Claude. Admirable as were his landscapes, however, his portraits are scarcely inferior in merit.

KY'ANITE, a mineral of a fine bright blue colour, and sometimes with a shade of green or gray. It is found both massive and crystallized, in six-sided prisms, with bases a little inclined.

KYANIZING, a process invented by John Howard Kyan for preserving timber from dry-rot and decay, by injecting into the pores of the wood a solution of corrosive sublimate or bichloride of mercury. Kyan was a practical chemist, born in Dublin in 1774, who died at New York on the 5th of January, 1850.

KYD, THOMAS, was one of those dramatic poets who immediately preceded Shakspeare. Three plays of his are extant—1, 'Cornelia; or Pompey the Great, his fair Cornelia's Tragedy,' a translation, respectfully executed, from the French of Garnier, printed in 4to, 1594, 1595; 2, 'The First Part of Jeronymo,' 1605, 4to; 3, 'The Spanish Tragedy, or Hieronymo is Mad Again,' of which there are many editions, the oldest known being of 1599, though the play was certainly printed earlier. All the three are in Dodsley's 'Old Plays.' As a writer of blank verse, Collier places him next to Marlowe, among the predecessors of Shakspeare.

KY'DIA, a genus of trees of the natural family of *Byttneriaceæ*, which is sometimes called *Sterculiaceæ*. The species are only two, found in the hilly parts of Hindustan, as far as the foot of the Himalaya mountains. *K. calycina* abounds in a bland mucilage, which is employed in clarifying sugar.

KYRIE ELEISON, a Greek phrase, signifying 'Lord have mercy.' It is the name given to a form of prayer common to the ancient Greek, the Roman Catholic, and the Anglican liturgies. In the Roman mass it follows the introit, and forms the introduction to the hymn, 'Gloria in excelsis Deo.' The Greek words are still used, being, as Dr. Milman says, one of many evidences of the predominance of the Greek element in the early Roman Church. In the English Prayer-book it is placed between the Creed and the Lord's Prayer in both morning and evening services.

L, the first of the letters called *liquids* or *semi-vowels*, is formed at that part of the palate which is near the teeth. It is therefore allied to the adjoining liquids *r* and *n*, and to the palatodental consonants. It is identical with the Greek *lambda* and the Hebrew *lamed*, and is found in almost every language. As a numeral, **L** represents fifty. The interchanges to which it is liable are as follows:—

1. **L** is interchangeable with *r*. Hence from the Greek or rather Latin *apostolo*, *epistola*, the French have derived *apostre*, *apôtre*; *épistre*, *épître*.

2. **L** with *n*, as *Barcino* (onis), *Barcelona*; *Ruscino*, *Roussillon*; *Bononia*, *Bologna* or *Boulogne*; *λίτρον*, *nitrum*; *anima* in Lat., Ital. *alma*.

3. **L** with *d*, as *St. Aegidius*, *St. Giles*; *gridiron*, meaning *grill-iron*; and the English title *admiral* is derived from the Spanish *almirante*. **L** is also interchangeable with *T*.

4. **Ll** in the middle of words with *li*. Examples of this are abundant in the French pronunciation of the *l mouillé*. Hence from the French *billards* is derived without much alteration of sound the English *billiards*. This change prevails between the Greek and Latin languages, as *φύλλο* and *folio*, 'a leaf'; *ἄλλο* and *alio*, 'other'; *ἄλλ* and *sali*, 'leap.' With these forms may be compared *Mallorca*, pronounced *Mayorca*, the Spanish name for *Majorca*. Lastly, the Portuguese write *lh* with the same sound.

5. **L** disappearing. Not very dissimilar from the preceding section is the Italian interchange of *pl*, *cl*, *fl*, with *pi*, *chi*, *fi*; as from *pleno*, 'full', *pieno*; *plano*, 'flat or low', *piano*; *clavi*, 'a key', *chiave*; *claro*, 'bright', *chiaro*; *clamare*, 'to call', *chiamare*; and *flor*, 'a flower', *fiore*; *Florenza*, once *Fiorenza*, now *Firenze*, the name of Florence.

This loss of an *l* after a consonant appears in other languages. The German *fliegen*, 'to fly,' has for its chief element *flug*, corresponding to the Latin *fug*. In the same language *fisperm* and *fispenn* both mean 'to whisper'; *flittich* and *fitlich* both mean 'a wing'; *blinzen* corresponds to the English words *blink* and *wink*.

6. **L** with *u*, particularly after an *a*. *Alfidenā*, 'a town,' or *Aufidena*; *ἐλεημοσύνη*, 'pity,' Ital. *limosina*, Fr. *aumône*, Eng. *alms*; Lat. *altari*, 'an altar,' Fr. *autel*; Lat. *aliqui-uno*, Ital. *alcuno*, Fr. *aucun*; Lat. *ulna*, Fr. *aune*. The French also contract the preposition and article *à le*, *à les*, to *au* and *aux*.

7. Many words beginning with an *l* once had other consonants before the *l*; as in Latin, *loco*, 'a place,' *liti*, 'a suit,' *lato*, 'broad,' were once preceded by *st*—thus, *stloco*, *stliti*, *stlato*. This explains how *lato* in Latin is the participle of *toll*. It must once have been *tlato*, corresponding to the Greek forms of the same root, viz., *τλη-τος*, *τλη-μων*, as well as *τολ-μη*.

8. **L** is very apt to appear in a root, sometimes

before a vowel, sometimes after one, as in the Greek words *καλι* or *κλη*, *βαλ* or *βλη*, &c. Where this slipping occurs after a sound like *k*, the *l* is apt to be converted into an *r*. Thus the Greek *σκαλεν*, 'poke,' is in Latin *scrutari* (compare the phrase *scrutari ignem*, 'to poke the fire').

LA, in music, used by the French and Italians, is synonymous with our note *A*.

LAALAND, a flat and exceedingly fertile island in the Baltic, belonging to Denmark. The area is 450 square miles, and the population 56,000. The surface is low and level. There are some rather extensive forests of beech and oak, and some beautiful gardens. It is one of the most fertile of the Danish islands, producing corn, hemp, hops, and apples. The chief town is Nakskov, which has a good harbour and coasting trade, principally in corn. The population is 3687.

LABARUM, the famous standard of Constantine the Great, which he designed in remembrance of the vision of a cross in the heavens that occurred to him on his march against Byzantium. The Greek historians describe it as a long pike surmounted by a crown of gold; the crown inclosing a monogram of the first two letters of Christ's name. From its shape it also served as an emblem of the Cross. A silken banner hanging from it was embroidered with the figures of the great emperor and his family. It was jealously preserved for many generations, and carried before the Greek armies in terrible emergencies, as if it could insure the safety of the empire. On Constantine's medals it is accompanied with the legend which he professed to have seen blazoned in the skies, *En touto nika* ('conquer by this.')

LABEO (Cuvier), a genus of fishes belonging to the *Cyprinidae*. The species of this genus resemble the true Carps in having the dorsal fin long, but they do not possess the strong spine of the anal and dorsal fins. The lips are very thick and fleshy, and more or less crenulated. There are no cirri. An illustration of this genus will be found in the *Cyprinus Niloticus* of Geoffroy St. Hilaire. The *Cyprinus fimbriatus* of Bloch and the *Catostomus cyprinus* of Lesueur also belong to the genus *Labeo*, which has no representative in the European seas.

LABIALS (Lat. *labium*, 'a lip'). The letters *B*, *P*, *V*, *F*, *M*, are so called, because the lip is chiefly employed in their pronunciation.

LABIATE. [*LAMIACEÆ*.]

LABIENUS. [*CÆSAR*.]

LABIOBARBUS (Lat. *labium*, 'a lip,' and *barbus*, 'bearded'), a genus of the family *Salmonideæ*.

LABLAB, a name of Arabic origin, which has been adopted by botanists to designate a genus of *papilionaceous Leguminosæ* of the tribe *Phaseoleæ*, or tropical pulse.

LABORATORY, the room in which chemical operations are performed. The requisites for the proper arrangement of, and the necessary instruments for a laboratory, may be seen at length in the late Professor Faraday's 'Chemical Manipulation.'

LABORATORY-ROYAL, a department of Woolwich arsenal for the manufacture of warlike stores, has been in existence for many years, and in 1855 was considerably enlarged and improved. Here are made shot, shell, bullets, percussion-caps, cartridges, and all kinds of ammunition. The machinery is of a very ingenious and powerful description. The annual cost of the Laboratory varied from 503,935*l.* in 1861 to 195,743*l.* in 1863. In the estimate for 1869-70 the cost was set down at 223,888*l.*; of which 86,200*l.* was for wages, 54,500*l.* for materials, and 7182*l.* for instruction and superintendence. The superintendent's salary is 975*l.*, his assistant's 440*l.*, and forty clerks are attached to the establishment.

LABOUR. [WAGES.]

LABOUR. [BASQUES, LE PAYS DES.]

LABRADOR is the name of a vast peninsula of British North America, between lat. 49° and 63° N., long. 55° and 79° W., bounded S. by the Gulf of St. Lawrence, E. by the Atlantic Ocean, W. by Hudson's Bay, and N. by Hudson's Straits. Its area is estimated at 170,000 square miles, and the population at 5000. This country was discovered by Cabot in 1496, and re-discovered by Hudson in 1610. It is very thinly peopled by wandering tribes of Indians, and in the northern coasts by nomadic Esquimaux. The table-land in the interior is very sterile; cariboo moss covers the rocks, and stunted spruce, birch, and aspen grow in the ravines. It is strewn with immense numbers of boulders, which are perched on the summits of the hills. The climate is less foggy than in Newfoundland, but very severe, the temperature in winter being about 30° below zero; and in the summer it does not rise above 85° Fahr. Indeed this immense region is quite unfit for the abode of civilized man; and though once rich in fur-bearing animals, and in cariboo or reindeer, it is now almost a desert.

The peninsula is divided into three parts—one belonging to Canada, comprising the country drained by the St. Lawrence; another on the coast of the Atlantic, called Labrador, is under the jurisdiction of Canada; and the third, called East Main, is included in the territory of Hudson's Bay.

The whale, seal, cod, salmon, and herring fisheries, off Labrador, employ during the season about 1000 decked vessels. Much of the produce is sent to Newfoundland before being exported to Europe. The total annual value of the fish, oil, &c., is estimated at 600,000*l.*

The European settlements on the east coast consist of Forteau and Bradore bays, Anse, Le Blanc, and the Moravian mission stations of Nain, Okhak, Hopedale, and Hebron. The mean annual temperature of Nain, the oldest settlement, although in about the same latitude as Edinburgh, is 4° or 28° below freezing point. The Hudson's Bay Company have several settlements on the west coast, or East Main.

LABRADO'RITE, Labrador feldspar, the constituents of which are silica, alumina, soda, and oxide of iron; specific gravity, 2.7.

LABRAX (Cuvier), a genus of fishes of the section *Acanthopterygii* and family *Percidæ*. The fishes of this genus are closely allied to the true Perches, but may be distinguished by the opercular bones being covered with scales, the absence of denticulations on the suborbital and interopercular bones, the operculum being terminated by two spines, and likewise by the tongue being almost entirely covered with minute and closely set teeth. There are two dorsal fins.

Examples.—*Labrax lupus* (the Basse, or Sea Dace), abundant in the Mediterranean; *Labrax lineatus* (the Rock Fish, or Striped Basse of the United States); and a second American species, *Labrax mucronatus*.

LA'BRIDÆ (*Labroides*, Cuvier), the family of Bream, or Rock Fishes, belonging to the order *Acanthopterygii*. The fishes of this family are of an oblong form, covered with scales, usually of a large size, formed of simple laminae, and with the external or posterior margin smooth; they have a single dorsal fin supported in front by spinous rays, each of which is generally furnished with a membranous appendage; the jaws are covered by thick fleshy lips; two upper pharyngeals are attached to the cranium, and together with a large lower pharyngeal are armed with teeth which are large and rounded, sometimes pointed or laminated, and generally very strong. The intestinal canal is without cæca, or, when these appendages are present, they are of small size, and there is a simple and strong natatory bladder.

The fishes of this family are generally most beautifully coloured; they frequent rocky places, spawning in spring or summer. Their flesh is held in no estimation.

The following genera are contained in the family Labridæ:—

1. *Labrus*, of which six British species are described by Mr. Yarrell ('British Fishes'). 2. *Cheilinus*. Locality, Indian Ocean. 3. *Lachnolaimus*. Locality, American seas. 4. *Julis*, the Rainbow Wrasse, a Mediterranean species (*Julis Mediterranea*), has been caught off the British coast. 5. *Anampses*. Locality, Indian seas. 6. *Crenilabrus*. Mr. Yarrell figures and describes four British species. 7. *Coricus*. Locality, Mediterranean. 8. *Epibulus*. Locality, Indian seas. 9. *Clepticus*. Locality, Antilles. 10. *Gomphosus*. Locality, Indian seas. 11. *Xirichthys*. Locality, Mediterranean and other seas. 12. *Chromis*. Locality, Mediterranean, the Nile. 13. *Cychla*. 14. *Plesiops*. 15. *Malacanthus*. 16. *Scarus*. To this genus, according to Cuvier, belonged the celebrated fish *Scarus Creticus*, which the ancients esteemed so highly for its flesh. 17. *Calliodon*. 18. *Odx*.

LA BRUYERE. [BRUYERE, LA.]

LABUAN. [BORNEO.]

LABURNUM, the common name of the early flowering European trees, named by botanists *Cytisus alpinus*, and *C. laburnum*. Laburnum is a native of the Alps of Europe, and is well known in gardens for the beauty of its pendulous racemes of beautiful yellow flowers. Every part of it is poisonous.

LABYRINTH (Greek, *labyrinthos*), a place involved in countless and almost inextricable sinuosities—a species of gigantic puzzle, such as the Maze at Hampton Court. In ancient history and mythology four famous labyrinths are described: one in Crete, which Dædalus built, at the instigation of Minos,

to inclose the Minotaur; one in the island of Meröe, devised by the Egyptian king Psammetichus, and composed of twelve palaces, all communicating with one another, and so divided into rooms and corridors that the person once astray within its walls could not hope to discover an egress without a guide. This was partly extant in the time of Pliny, and was probably a place of royal sepulture. A third labyrinth existed, it is said, at Lemnos; and a fourth was built by Porsenna, king of Etruria. The latter is described by Varro, but, undoubtedly, is a pure myth.

LABYRINTHODON (literally, labyrinth-toothed), a name given to a remarkable frog-like saurian of the New Red Sandstone formation. No complete skeleton has been found. The fragments of remains and the footprints of the animal left on the sandstone, have been used by the comparative anatomist to determine the form of the Labyrinthodon and its place in the zoological scale. It is generally held by geologists to be the same as the *Cheirotherium*. In handbooks of geology figures of this animal are given; but it should be borne in mind that these are much indebted to the imagination of their authors.

LA CAILLE, NICHOLAS LOUIS DE, was born at Rumigny, in the department of Ardennes, March 15, 1713. His father, a retired military officer, was in the service of the duchess of Vendôme, and, himself attached to science, he endeavoured to cultivate the same taste in his son. He died, however, while the latter was at the college of Lisieux, and his son was enabled to continue his studies by the generosity of the duke of Bourbon. He chose theology as his profession; but in passing his first examination he showed so much frankness in his answers to some questions proposed by a doctor of the old school, that this examiner would have refused him his degree but for the remonstrances of the rest. This incident discouraged him, and he remained content with the title of abbé, beyond which he never proceeded. He had previously turned his attention to astronomy under great disadvantages; and upon his renunciation of theology he was introduced to James Cassini, who gave him employment at the observatory. In the following year, in conjunction with Maraldi, he made a survey of part of the coast of France, where the talent which he showed occasioned his being employed in the verification of the arc of the meridian. This operation (in which Cassini de Thury took a part) commenced at the beginning of May, 1739, and before the end of the year he had completed the triangulation from Paris to Perpignan, had measured three bases, made the requisite astronomical observations at three stations, and had taken a prominent part in the measurement of a degree of longitude. In the winter of 1740 he extended his operations to the mountains of Auvergne, in order to test some suspicions which he had formed upon the accuracy of Picard's measurement. The result of these labours was the complete establishment of the gradual increase of the degree in ascending from the equator to the poles; which, though long known to be theoretically true, had not previously been confirmed by measurement. In the meanwhile La Caille had been appointed to a chair of mathematics in the Mazarin College, the duties of which he fulfilled with care, and for which he published treatises on geometry, mechanics, astronomy, and optics. In 1751 he made

his celebrated voyage to the Cape of Good Hope, where he remained nearly four years. His object was to form a collection of southern stars, and up to the present time his results have been highly esteemed, though the labours of Herschel and others have made important additions. He determined the places of about ten thousand stars, and grouped them in constellations; measured a degree of the meridian at the Cape, and made a survey of the Mauritius and Island of Bourbon. He returned to Paris in 1754, and occupied himself in the preparation of his 'Fundamenta Astronomiæ,' for the publication of which he engaged to furnish a bookseller with almanacks for ten years. At the end of 1761 he was seized with gout, but he remained during the winter employed in his observatory, passing several nights upon cold stones in his scientific investigations: a fever was the consequence, and he died March 21, 1762, aged forty-nine years.

La Caille was an astronomer whose observations will have the highest value as long as the science is cultivated; which cannot be said of others, his superiors in originality of discovery. Lalande said of him that he alone had made more observations than all his contemporaries put together; which Delambre states would be no exaggeration, if spoken of the twenty-seven years during which he laboured. But though his utility was much increased by his extraordinary activity, industry, and honesty, yet his reputation was still more indebted to the genius which he displayed in producing exactness out of imperfect instruments.

LAC. [MONEY.]

LAC (Greek, *gala, galaktos*), a resinous substance, which in the East Indies flows from certain trees in the state of a milky fluid, on account of the puncture made by a small insect, the *Coccus ficus*, in their branches, in order to deposit its ova. The trees are principally the *Ficus indica*, *Ficus religiosa*, and *Rhamnus jujuba* and a species of *Celtis*.

There are three kinds of lac known in commerce, distinguished by the names of *Stick Lac*, *Seed Lac*, and *Shell Lac*. *Stick Lac* is the substance in its natural state; it is of a reddish colour, and incrusts small twigs; when broken off and boiled in water it loses its red colour, and is then termed *Seed Lac*; and when melted and reduced to the state of thin plates, it is called *Shell Lac*. The imports are given in the article *GUM*.

The different varieties have been analyzed, with the following results:—

	Stick Lac.	Seed Lac.	Shell Lac.
Resin, ...	68.0	88.5	90.9
Colouring matter, .	10.0	2.5	0.5
Wax, ...	6.0	4.5	4.0
Gluten, ...	5.5	2.0	2.8
Foreign bodies, .	6.5	—	—
Loss, ...	4.0	2.5	1.8
	100.0	100.0	100.0

Laccin is the substance which remains after the lac has been repeatedly digested in alcohol and water. It is insoluble in water, alcohol, or ether, but is dis-

solved by concentrated sulphuric acid. Solution of potash also dissolves it readily.

Laccic Acid separates from solution in water, by spontaneous evaporation, in crystalline grains. With the alkalis and with lime it forms salts which are soluble in alcohol and in water, and are deliquescent.

Cochinellin, or the colouring matter of stick lac, is similar to that of cochineal, used for the same purposes, and yields a scarlet colour little inferior to it.

Lac Dye and *Lac Lake*, two preparations of lac which are manufactured in the East Indies, are used to a very considerable extent in scarlet dyeing.

LACCADIVE ISLANDS are situated in the Indian Ocean, opposite the coast of Malabar, between 10° and 13° N. lat., and 72° and 75° E. long. They are seventeen in number, but only eight are inhabited. They consist chiefly of low coral formations, and are surrounded with deep water. The largest of these islands, Anderot, is only three miles in length and one mile broad. They are based on coral reefs, and are nearly flat. The principal products are coir, jaggery, cocoa and betel nuts, with some rice, sweet potatoes, and small cattle. An annual tribute of 1000*l.* is paid to the British district of Cananore, in the presidency of Madras. The population is said to amount to between 6000 and 7000.

LACE (Ital. *laccio*). This fabric differs essentially in form and appearance from the products of an ordinary loom, and until the early part of the present century was made without the employment of machinery. The finest and most costly kinds are still made by hand, and require both skill and patience of no ordinary kind. (See Plate for specimen of lace curtain.) The implements which are used by hand lacemakers are few in number, and inartificial in their character. They consist of a pillow or cushion, a series of bobbins or small cylindrical pieces of wood round which the thread or silk employed is wound, and pins which are stuck into the cushion and around which the threads are twisted, the pattern of the lace being determined by the disposition of the pins, and this again being regulated by holes pierced in a piece of parchment which is laid upon the cushion. It is not possible, however, to give in writing an intelligible description of the hand lace manufacture. The principal seat of the trade in England is Buckinghamshire; but the most esteemed qualities are imported from foreign countries—especially Belgium and France—and is generally known by the name of the town in which it was made. Of late years lace-making, as formerly conducted, has very much declined in this country, owing to the greater cheapness of machine-made lace, better known as bobbin-net. The manufacture is principally carried on in and about Nottingham, Leicester, and Derby, and in the west of England, especially at Honiton in Devonshire. There are also a large number of females employed in the trade in the north of Ireland. The machines by which this bobbin-net is made are among the most exquisite pieces of mechanism employed in manufactures. They were first invented by Mr. John Heathcoat in 1809, and have since been much improved by other makers. Heathcoat, like many other inventors, was driven from his residence at Loughborough, in Leicestershire, by the hand lacemakers of the midland counties. He went to live at Tiverton, and thus introduced the trade

into the west of England. His machines ultimately bore down all opposition at Nottingham and elsewhere. Machine lace is now made as wide as five yards; and the manufacture has wonderfully increased at Nottingham (which may now be looked upon as the head-quarters of the trade) during the last fifteen years. There are about 180 wholesale lace firms in that town alone. Lace-making machines have also been introduced into France and Belgium, chiefly from England.

The following were the imports of lace into the United Kingdom in 1867:—

	Value.
Pillow of thread and cotton, . . .	£68,726
Pillow of silk, ...	30,942
Machine or imitation, ...	91,789
Mohair or worsted, ...	200

Nearly the whole came from France. (*The History of Lace from the Earliest Period*, by Mrs. Bury Palliser, third edition, 1868.)

LACE-BARK TREE. [*DAPHNE*.]

LACEDÆMON, LACEDÆMONIANS. [*SPARTA*.]

LACÉPÈDE, BERNARD GERMAIN ÉTIENNE DE LA VILLE, COMTE DE, was born at Agen, in France, December 26, 1756. His youth was spent at home in the cultivation of literature and science; and when, for the sake of nominal employment, he obtained a commission in the army, it was in a regiment where he had no duties to perform. This enabled him to cultivate his musical taste, but he abandoned any public display of his talents in this line, after the failure of an opera which he was induced to bring out.

In 1781 he published an essay on natural and artificial electricity, and in 1782 a treatise on physics, entitled '*Physique Générale et Particulière*.' These works did not meet with success. Buffon, however, was much pleased with them, and proposed to him to continue his '*Natural History*,' and in 1785 offered him the appointment of curator and sub-demonstrator in the Cabinet du Roi. Lacépède gladly accepted the offer, and left the army. He now applied himself with energy to natural history, and published his '*Histoire Naturelle des Quadrupèdes, Ovipares, et des Serpents*' in 1788–89. Lacépède formed classes, orders, and genera, but his arrangement was, like that of Linnæus, artificial and unphilosophical, founded only on external characters, without reference to internal organization. When the Jardin du Roi was converted by the Convention into a public school, and named the Museum of Natural History, a new chair of zoology was created for him. In 1798 he brought out the first part of his '*Histoire Naturelle des Poissons*.' In 1804 his '*Histoire Naturelle des Cétacés*' was published. He was a member of the Institute at the time of its formation, and afterwards of the Academy of Sciences. He died October 6, 1825.

LACERTA (the *Lizard*), a constellation of the northern hemisphere, surrounded by Andromeda, Cepheus, Cygnus, and Pegasus, found by Hevelius.

LACE'RTIDÆ, or *Lacertians*. Under the family name of *Lacertians* Cuvier arranged—

1. The *Monitors* and their subdivisions, viz., the *Monitors* properly so called, including the *Ourans* of the Arabs (*Varanus*), &c.; the *Dragons* (*Crocodil-*

urus of Spix, *Ada* of Gray); and the *Sauvegardes* (*Monitor* of Fitzinger and Ameiva).

2. The *Lizards* properly so called. This second group comprises, according to Cuvier, the genera *Lacerta*, *Algyra*, and *Tachydromus*.

MM. Duméril and Bibron make the *Varanians*, or *Sauriens Platynotes* ('broad-backed Saurians'), a family which comes immediately after the *Geckotians* in their *Erpétologie*. They allow that the *Varanians* are nearly allied to the *Lacertians*, as modified by them, and rest the distinctions of the former family from the latter—1st, On the presence in the latter of polygonal scales which cover the head; 2nd, on the form of the scales of the back and of the belly, and their non-compressed tail; and 3rd, on the form and disposition of the teeth, which are not distant, obtuse, and conical, but placed on the same line, and trenchant at their summit in the antero-posterior direction.

As the family of the *Varanians* is highly interesting, and the differences between that family and the *Lacertide* are not very wide, it will be most instructive to treat of both in the same article. [VARANIDÆ.]

LACHESIS, in Zoology, a genus of venomous serpents, allied to the viper. In Mythology, one of the Parcae, or Fates, who presided over futurity, and was represented as spinning the thread of life.

LACHRYMAL ORGANS. [EYE.]

LACHRYMATORY (Lat. *lachryma*, 'a tear'), a small glass phial, or globular earthen vessel, with a long neck, frequently found in the ancient Roman sepulchres. In these vessels it is supposed the tears of the friends of the deceased were dropped, and preserved with the ashes contained in the funeral urn. They are often found in our museums, and in the cabinets of the curious.

LACISTEMA'CEE, a small and obscure natural order of incomplete exogenous plants, containing a few arborescent species, inhabiting the woods of equinoctial America, in low places.

LACONICA, called by the Roman writers *Laconia*, a country of ancient Greece, was bounded on the W. by Messenia, on the N. by Arcadia and Argolis, and was surrounded by the sea on the E. and S. Laconica is a long narrow valley, running from north to south, between two mountain masses which stretch from Arcadia to the southern extremity of the Peloponnesus: the western range, which terminated in the promontory of Tænaron, now Matapan (36° 28' N. lat.), the most southerly point of Greece, was called Taygetus; and the eastern, terminating in Cape Målea, was known by the names of Parnon, Thornax, and Zarex. Between the mountains which form the eastern boundary of the valley of the Eurotas and the sea there was a narrow strip of land, which contained the towns of Delium, Minoa, and Epidaurus Liméra, belonging to Laconica. The area of Laconica was probably about 1896 square miles. The district of Thyreatis, on the borders of Argolis, was conquered by the Spartans about 547 B.C.

There were no large towns in Laconica except Sparta. [SPARTA.] One of the most ancient towns was Amyclæ, the residence of the Achæan kings, situated a little to the south of Sparta, in a fertile plain.

The Léleges, according to the most ancient traditions of Laconica, were the earliest inhabitants. At the time of the Trojan war Laconica was in possession of the Achæans, who settled in Laconica at a very early period, and probably conquered the Léleges. During the reign of Tisámenus Peloponnesus was invaded by the Dorians, and Laconica fell to the share of Aristodémus, or his sons Eurýsthenes and Procles. The condition of the original inhabitants of the land, and their relation to their Dorian rulers, belong to the history of SPARTA.

The area of the modern government of Laconica is 1632 square miles, and the population 112,910. The principal town is Mistra. [GREECE.]

LACONISM, a brief, sententious, pointed saying, so called from the mode of expression popular among the ancient Lacedæmonians. In English, the Rev. Charles Cotton's 'Laconics' may be cited as an example.

LACQUERING. [JAPANING.]

LACTANTIUS, LUCIUS CÆLIUS (or *Cæcilius Firmianus Lactantius*), one of the Latin fathers, lived at the end of the third and the beginning of the fourth century. He is generally supposed to have been an African. On the invitation of Diocletian, he went to Nicomedia, where he taught rhetoric. He became afterwards preceptor to Crispus, the son of Constantine, in Gaul. The time of his death is not known.

His chief works are the 'Divine Institutions,' in seven books, written in reply to two heathens who wrote against Christianity at the beginning of Diocletian's persecution; a treatise on the 'Workmanship of God;' on the 'Wrath of God;' and a work entitled 'Symposion,' which he wrote when very young.

Complete editions of his works were published by Hermann at Göttingen in 1736, and by the Abbé Lenglet, 2 vols. 4to, Paris, 1748.

LACTEALS (from *lac*, 'milk') are so called from their containing an opaque, white, milky fluid. They are the system of vessels by which the chyle, or nutritive part of the food, is conveyed from the intestines to the left subclavian vein, in which it is mixed with the blood. They have their origin in the villi of the small intestines, which are short hair-like processes, each consisting of a fine network of lacteal vessels, surrounded by capillary arteries and veins. [DIGESTION.]

LACTIC ACID. This substance exists in milk, and in larger proportions when it has become sour; it also exists in various other animal fluids, and in many vegetable juices. Lactic acid is colourless, inodorous, very sour, and may be so concentrated as to have a specific gravity of 1.215; it attracts moisture from the air, and dissolves in water and alcohol in all proportions. When concentrated lactic acid is heated gradually to 265°, it becomes more fluid, darker-coloured, and yields acetic acid and inflammable gas, charcoal, and a white solid matter, which is both sour and bitter; when this is dried between folds of bibulous paper, and afterwards dissolved in alcohol, it yields perfectly white rhombic crystals, which are anhydrous lactic acid (= C₁₂ H₁₀ O₁₀). The pure uncrystallizable acid, soluble in alcohol and ether, is represented by the formula C₁₂ H₁₀ O₁₀, 2 HO.

The lactates are not an important class of salts. Lactate of ammonia is deliquescent and uncrystallizable. Lactate of potash and lactate of soda are deliquescent, soluble in alcohol, and by evaporation in vacuo they become crystalline masses. Lactate of lime and lactate of barytes yield gum-like products. The lactates of alumina, peroxide of iron, and copper, do not crystallize; but lactate of magnesia and lactate of zinc crystallize in quadrilateral prisms, and lactate of silver in colourless needles.

LACTOMETER (Lat. *lac* and *metrum*), an instrument for ascertaining the different qualities of milk. Several sorts have been invented, one consisting of a glass tube a foot long with a funnel at the top. The upper two inches of the tube are marked in small divisions; and when the instrument is filled with milk to the height of one foot, the depth of cream it yields is noted by the gradations on the upper part.

LACTUCA, a genus of plants belonging to the natural order *Composita*. *L. virosa*, Acid Lettuce, is found on hedges, old walls, and the skirts of fields throughout Europe. It yields a milky juice, which contains *Lactucio acid*. [**LETTUCE.**] *L. scariola*, Prickly Lettuce, is not so acid as *L. virosa*, but possesses the same properties.

LACTUCARIUM is obtained from the *Lactuca sativa*, being the inspissated milky juice of the plant, and which is at first white, but afterwards, by exposure to the air and sun, concretes and becomes brownish. The juice of the leaves only should be collected before the flowering has begun; puncturing the leaves is the best mode of procuring it.

The inspissated concrete juice resembles opium in its action, but is much feebler. In pulmonary diseases it is often a useful sedative. The common lettuce also possesses sedative properties, and eaten towards bedtime has often contributed to procure rest in cases of morbid wakefulness, or to allay pains of the stomach.

LADAKH, or MIDDLE TIBET, is a kingdom in Asia, situated to the east of Cashmere, from which it is separated by a branch of the Himalaya mountains. On the east and north it is bounded by Tibet. It is part of the central plateau of Asia, and has a general elevation of about 9000 feet. The surface is a continual succession of ascents and descents, many of which are very steep. Through the middle of the country runs the valley of the river Indus, which passes the towns of Roodok and Leh, and receives the waters of the Shayuk and other tributaries. There are several lakes, most of which are salt, and furnish great quantities of that article.

The soil is sterile, and the climate severe and variable. The rays of the sun are oppressive. In September, at an elevation of 15,500 feet, the thermometer, resting on the rocks, reached 158°; at 14,500 feet, on the sand, it gave 130°; and in a tent, pitched at a height of 13,000 feet, it reached 110° Fahr. This phenomenon is attributed to the rarefaction and tenuity of the atmosphere, from elevation, and absence of moisture. From December to February the thermometer ranges from 10° to 20° Fahr.; yet the mountain sides being carefully embanked with stone dykes, and industriously cultivated, pretty good crops of wheat, barley, buckwheat, apples, and apricots are grown. Prangos, a peculiar

kind of fodder, is abundant. The minerals comprise sulphur, iron, lead, copper, and gold, which abounds in the beds of the rivers, but is prohibited by the government from being collected. The transit trade with all the neighbouring regions is extensive, and conducted mostly by means of mules and sheep.

Leh, the capital of the country, contains about 1000 houses, each several stories high, and substantially built. The population is about 4000. There are several bazaars, each containing from twelve to fourteen shops. *Leh* is a place of great trade, being the principal entrepôt for the shawl wool, and three great fairs are annually held here, at which merchants attend from China, Tibet, the Punjab, and Cashmere. It has several temples, and the palace of the rajah is of great size, though rudely finished. *Roodok*, on the right bank of the Indus, but higher up the river, is another place of considerable traffic.

The inhabitants of Ladakh belong to the same race as the inhabitants of Tibet. They are stated to number altogether about 125,000, and are good farmers, peaceable, honest, and hospitable. Lamaism is the prevailing religion. [**LAMAISM.**]

The armed force consists of a peasant militia, and Ladakh has been repeatedly under the rule of more powerful neighbours. During the life of Runjeet Singh it formed a part of his dominions.

Ladakh has a considerable commerce with surrounding countries, the chief article of which is the wool of the goats, which is used in the manufacture of Cashmere shawls.

LADANUM, sometimes written *Labdanum*, but incorrectly, a gum resin produced by several species of *Cistus*. *C. ladaniferus*, *C. Creticus*, *C. laurifolius*, and *C. Ledon* are usually mentioned as the species which are indigenous in the Grecian islands, in Spain, Italy, and the south of France. That obtained from the Levant is the most celebrated. The juice exudes upon the leaves and branches of these shrubs, and is collected, according to Tournefort, by means of an instrument resembling a rake, with leather thongs instead of teeth, which is drawn over the plant; the juice adheres to the thongs, and is afterwards separated.

LADIES OF THE QUEEN'S HOUSEHOLD, **THE**, consist of the mistress of the robes, the ladies of the bedchamber, the bedchamber women, and the maids of honour. The mistress of the robes has superintendence of all the others, and the custody of the robes. On state occasions she must see that the ceremony of robing the Queen is properly performed. The ladies of the bedchamber and the bedchamber women, of each of whom there are eight, with several extra ladies, are personal attendants upon Her Majesty. There are also eight maids of honour, who in rotation perform the duty of accompanying the Queen on all occasions. They are styled 'honourable,' even if not entitled to that distinction by birth. [**BEDCHAMBER, LORDS AND LADIES OF.**]

LADING, BILL OF. [**BILL OF LADING.**]

LADOGA, Lake. [**RUSSIA.**]

LADRONE ISLANDS, a group in the North Pacific, belonging to Spain, extend between 13° and 20° 30' N. lat., and between 144° and 145° 30' E. long, and are about 20 in number. They are mostly of a volcanic character, and are very rugged;

but they yield nearly every kind of intertropical product, such as cotton, rice, indigo, Indian corn, sugar, cacao, cocoa nuts, tobacco, plantains, &c. Cattle, horses, mules, and asses are numerous, and the llama has been introduced from Peru, and thrives well on the mountains. The principal island is Guajan, which is about 90 miles in circumference. Its capital, S. Ygnacio de Agaña, is fortified, and has an open roadstead, and a good harbour a few miles farther north. Tinian, another island, exhibits extensive ruins, which indicate that these islands were once inhabited by a people well acquainted with the arts of civilization. The islands were discovered by Magelhaens in 1521, and were settled by the Spaniards in the middle of the next century. The aborigines have now almost disappeared, and the Spaniards are few, the chief inhabitants being settlers from Mexico and the Philippines. The total population of these islands was once 100,000, but is now greatly reduced, probably not more than about 6000.

LADY (Saxon, *hlæfdiga*), a title of distinction corresponding to Lord. It belongs to peeresses, and the wives of peers, as a prefix to the peerage title. The daughters and daughters-in-law of dukes, marquises, earls, and peers, are also entitled to it. To the wives of baronets and knights is legally given the prefix 'Dame,' but they are now by courtesy always addressed as 'My Lady' and 'Your Ladyship.'

The word *lady* is used in common speech as a correlative of gentleman. For its origin, see Professor Max Müller's *Lectures on Languages*, 2nd series, p. 235.

LADYBIRD (*Coccinella*), a genus of coleopterous insects. The family *Coccinellidae* consists of twenty-three genera and of more than 500 species. Their bodies are hemispherical, and spots occur on their elytra, or wing-cases. They are very pretty beetles, and many of them are well known. The most common is the form which has seven spots on its elytra; it is abundant in this country, and a favourite with most observers. [TRIMERA.]

LADY-CHAPEL, a chapel frequently attached to cathedrals and ancient churches, dedicated to the Virgin Mary. They are usually elegant specimens of architecture, and have often been used as burying places for renowned and illustrious personages. Henry VII.'s Chapel is the Lady-chapel of Westminster Abbey.

LADY-DAY, the day of the Annunciation of the Holy Virgin, March 25. It is one of the immovable festivals of the English Church, and precedes the day of Christ's nativity by nine months.

LADY'S SLIPPER. [CYPRIPEDIUM.]

LÆMODIPODA, Latreille's fourth order of *Crustaceans*, placed by him between the *Amphipoda* and the *Isopoda*. He describes them as being the only forms among the *Malacostraceans* with sessile eyes, whose posterior extremity does not present distinct branchiæ, and which have hardly any tail, the last two feet being inserted at that end, or the segment to which they are attached being followed by not more than one or two other joints, which are very small. They are also, he states, the only ones in which the two anterior feet (which agree with the second jaw-feet) make a part of the head.

The *Læmodipoda* of Latreille have all four setaceous antennæ carried upon a peduncle of three joints,

mandibles without palps, a vesicular body at the base of four pair of the feet at least, beginning with the second or third pair, reckoning those of the head. The body, which is most frequently filiform or linear, is composed (reckoning the head) of from eight to nine joints, with some small appendages, in form of tubercles, at its posterior and inferior extremity. The feet are terminated by a strong hook. The four anterior feet, of which the second are the greatest, are always terminated by a monodactylous claw. In many the four succeeding feet are shortened, less articulated, without any hook at the end, or rudimentary, and not at all fit for ordinary use. The females carry their eggs under the second and third segments of the body, in a pouch formed by approximated scales.

The *Læmodipoda* are marine, and Savigny considers them as approaching the *Pycnogonids*, and making, with that form, the passage from the *Crustaceans* to the *Arachnids*.

Latreille brought the forms under one genus, *Cyamus*, with certain subdivisions and subgeneric appellations. (Cuvier's *Règne Animal*.)

LA FAYETTE. [FAYETTE, LA.]

LAFITTE, JACQUES, the celebrated French banker and financier, was born in 1767; and in the banking-house where he was first employed as a clerk, he rose to be cashier and partner, and afterwards became the head of the most eminent bank in France. Having obtained this distinguished position, he was elected a member of the Chamber of Deputies. He strongly advocated liberal measures and liberal opinions, and eventually rendered himself so popular, that when Charles X. was driven from the throne, his influence, notwithstanding the general wish for a republic, was mainly instrumental in electing the citizen king, Louis Philippe, to the throne. The revolution, however, was followed by so many commercial revulsions, which fell with overwhelming pressure on the house of Lafitte, that he was obliged to suspend payments. Yet so much sympathy was excited on his behalf, that a public subscription was entered into, and nearly a million and a half of francs raised for his use. It appeared, however, that after the payment of all demands, he was in the clear possession of nearly 280,000*l*. He died, full of years and honours, in 1844.

LA FONTAINE. [FONTAINE, LA.]

LAGENARIA, a genus of plants belonging to the natural order *Cucurbitaceæ*. *L. vulgaris*, common Bottle-gourd, has a fruit in shape like a bottle, when ripe of a pale yellow colour, sometimes six feet in length. When dried it becomes hard, and is used to contain water; it is then of a pale bay colour. In its wild state this plant produces a poisonous fruit. This species grows abundantly in Egypt and Arabia.

LAGERSTRE'MIA, a genus of plants of the natural family of *Lythraceæ*. The species are few in number, but most of them are highly ornamental.

LA'GO MAGGIO'RE, the ancient *Lacus Verbanus*, the largest lake in Italy, extends about 40 miles in length from north to south, separating Lombardy from Piedmont, and stretching at its northern extremity into the Swiss canton of Tessin. Its greatest breadth is 8 miles; but it is much less at the north and south extremities, and the average

is only two miles. The elevation of its surface above the sea is 678 feet, and its greatest depth is 1800 feet. The principal affluents of the Lago Maggiore are—the Toccia, which comes from the Val d'Ossola; the Maggia, which flows through the valley of that name; the Ticino, coming from the St. Gothard; and the Tresa, which flows out of the neighbouring lake of the Lugano. The outlet of the lake is formed by the Ticino, which issues from the Lago Maggiore at Sesto, and divides Lombardy from Sardinia to its junction with the Po. About the middle of the length of the lake, and in its broadest part, where it forms a gulf indenting the western shore, is a group of beautiful islands, called Isole Borromée, from the family name of the proprietor. They are four in number, Isola Madre, Isola Bella, Isola dei Pescatori, and the Isolino, the smallest of all. The Lago Maggiore abounds with fish; and a considerable trade is carried on in steamboats and barges between the various points of its coast. The Simplon road follows its western shore from Feriolo to Arona. The climate of the lake is cool, owing to the proximity of glaciers; and it is subject to sudden thunderstorms in summer. The granite mountains which surround it on the north and west, and the vineyard-covered hills on the south and east, render its scenery a combination of wild grandeur and soft beauty.

LAGOMYS, a genus of animals belonging to the order *Rodentia*, or gnawers, and family *Leporida*. They have short ears, no tail, and very strongly developed incisive teeth. They are natives of Asia. The Sadajac (*Lagomys alpinus*) is a native of Siberia. The calling hare (*L. pusillus*) is found in Russia. It is noted for its piping call, and, indeed, but for this would seldom be captured, as it burrows in remote and inaccessible localities.

LAGOON, or LAGUNE (Lat. *lacuna*). Lagoons are sheets of water formed either by the encroachments of rivers or seas upon the land, or by the separation of a portion of the sea by the intervention of a bank. Thus there are fluvial and marine lagoons. The former are not confined to the lower parts of water-courses, though they are most frequently there. Marine lagoons are the most common. They are formed sometimes by the encroachments of the sea, and sometimes by the throwing up of a bar or bank, which eventually divides off a portion of the sea altogether, or leaves merely a small opening. In Europe there are many marine lagoons: the Adriatic, on its north and north-western parts particularly, is full of them. The Zuyder Zee is a vast lagoon.

LAGOPHTHALMIA, a disease, generally a paralytic affection, in which the eye cannot be closed. Its name (from the Greek *lagos*, 'a hare,' and *ophthalmos*, 'an eye') refers to the popular idea that hares sleep with their eyes open.

LAGOS. [ALGARVE.]

LAGOS. [GUINEA.]

LAGRANGE, JOSEPH LOUIS DE, was born at Turin, 25th January, 1736. His parents were Joseph Luis Lagrange and Marie Thérèse Grass, the daughter of a physician at Cambiano. His father held the office of treasurer of war at Turin, and had once been in affluent circumstances, but had ruined himself by injudiciously entering into hazardous speculations. To this circumstance, which was then regarded as a misfortune, Lagrange himself has frequently attri-

buted a considerable share of his subsequent fame and happiness. 'Had I been rich,' he has been heard to say, 'I should probably not have become a mathematician.'

In the early part of his studies he manifested no particular love either for the pure mathematics or the physical sciences. His chief delight consisted in the perusal of the Latin authors, especially the works of Cicero and Virgil. These, however, were soon superseded by the synthetical writings of the ancient geometers, and these in their turn gave place to the more powerful analysis of modern times. The perusal of a memoir by Dr. Halley ('Phil. Trans.,' 1693) 'On the superiority of modern Algebra in determining the foci of Object-glasses,' is said to have convinced him of the utter inadequacy of geometrical methods as instruments of investigation; and it is not improbable that this might have been the occasion of his selecting the path which he thenceforth pursued with so much honour to himself and so great advantage to science.

Before he attained the age of nineteen he was appointed to the professorship of mathematics at the military college of Turin, where by far the greater part of his pupils were older than himself. The year following (1755) he addressed a letter to Euler, relative to the isoperimetric problems, and that of the curve of quickest descent, which had engrossed so much of the attention of the principal mathematicians of the day, and of Euler in particular; but owing to the want of general methods, their labours had proved but partially successful. Each problem had been resolved by methods peculiar to itself, and the solutions rested upon artifices unsatisfactorily indirect. In this letter Lagrange communicates the germs of his calculus of variations.

In 1758 he took an active part in the foundation of the Royal Academy of Turin, in which he was unanimously chosen the director of the physico-mathematical sciences. The following year appeared the first volume of the 'Transactions' of that Society, consisting principally of the researches of Lagrange on the propagation of sound, and on the integration of differential equations, and those of finite differences.

The calculus of variations is eminently important in many branches of the mathematics, as in the determination of the maxima and minima values of indefinite integral formulae, &c.; but its utility is most conspicuous in the higher branches of physical astronomy.

When the Academy of Berlin was threatened with the departure of Euler for St. Petersburg, Frederick renewed his importunities to the great French *savant* D'Alembert to succeed him. [D'ALEMBERT.] D'Alembert however, from various motives, being unwilling to quit his native country, suggested that the proffered honour might be conferred upon Lagrange, who was accordingly appointed professor of the physical and mathematical sciences, and continued for more than twenty years to enrich the memoirs of the Academy with his researches in physical astronomy and other subjects of importance. Lagrange quitted Berlin after the death of Frederick, not being satisfied with the treatment he received from his successor. He had previously been invited by the ministers of Louis XVI. to settle in Paris. In 1772 he was elected foreign associate of the

Royal Academy of Paris, and in 1787, on his arrival at the French capital, received the honorary title of veteran pensioner. Apartments were allotted to him in the Louvre; and here, surrounded by the principal mathematicians of the day, he continued to live happily up to the time of the Revolution. After this he began to be subject to fits of melancholy, which so far increased upon him that he has been heard to say that his enthusiasm for the sciences was extinguished, and that his love of physical research had disappeared. He was successively appointed professor of mathematics to the normal and polytechnic schools, member of the Institut, of the Board of Longitude, grand officer of the Legion of Honour, and Count of the empire. He died at Paris, the 10th April, 1813, in his seventy-eighth year. His remains were deposited in the Pantheon, and his funeral oration was spoken by his illustrious friends Laplace and Lacépède.

'Among those who have most effectually extended the limits of our knowledge,' said Laplace, in his funeral oration, 'Newton and Lagrange appear to have possessed in the highest degree the happy art of detecting general principles, which constitutes the true genius of science. This art, joined to a rare elegance in the exposition of the most abstract theories, characterized Lagrange.' His work on Mechanics, resting upon the method of variations of which he was the inventor, flows wholly from a single formula, and from a principle known before his time, but of which no one but himself was able to appreciate the importance. 'Among the successors of Galileo and Newton,' says Professor Hamilton, speaking of the theoretical development of the laws of motion, 'Lagrange has perhaps done more than any analyst to give extent and harmony to such deductive researches, by showing that the most varied consequences respecting the motions of systems of bodies may be derived from one radical formula; the beauty of the method so suiting the dignity of the results as to make of his great work a kind of scientific poem.'

LAGRIIDÆ (*Lagriaria*, Latreille), a family of coleopterous insects of the section *Heteromera*. Latreille assigns to it the following genera: *Lagriaria*, and, with a doubt, *Hemipeplus*.

LAGURUS, a genus of plants belonging to the natural order *Gramineæ*. *L. ovatus*, the only species, is found in sandy places in Guernsey, and on the continent of Europe.

LAHORE, the capital of the Punjab, British India, is situated in 31° 27' N. lat., 74° 26' E. long., on the south-eastern bank of the Ravee, the middle of the five rivers which give name to the country. It is a place of great antiquity, and was the residence of the first Mohammedan conquerors of Hindustan, before they succeeded in establishing themselves in the central parts of the peninsula. The city and suburbs are of great extent, and the population is said to amount to 95,000. The city of Lahore is inclosed by a double line of defences, the outer one being about 7 miles in circuit. It contains many large and handsome mosques and Hindoo temples, and around it for many miles are extensive Mohammedan ruins, with the fine tomb of the Emperor Jehangire, and the garden of Shah Jehan. There is also a citadel, containing the palace of the Sikh sovereigns. Under the Mogul emperors, Lahore was

of much greater extent, and is said to have contained 1,000,000 inhabitants. In 1748 it fell into the hands of Ahmed Shah; in 1798 Runjeet Singh was invested governor and rajah, but as he chose Umritsur for his head-quarters, Lahore rapidly declined. The city was taken possession of by the British after the final defeat of the Sikhs in 1849. In the fort are preserved the hair, sandals, and staff of Mohammed, brought by Timur to India, and long held by Runjeet Singh, who refused a lac of rupees for one of the sandals.

Lahore has a very successful government school, in which the upper class is devoted to the sons of natives of rank, and which usually has 500 pupils in training. There are several other schools, a fine gaol, penitentiary, lunatic asylum, and a medical college. The town is the see of a bishop. Its markets are well supplied, but the streets are narrow and gloomy, and the bazaars do not exhibit much appearance of wealth, the commerce of the Punjab being centred at Umritsur. A line of railway connects the latter place with Lahore, and is one of the most important public works lately constructed in that portion of the empire. The Punjab Railway, 252 miles in length, also runs through Lahore, and extends from Umritsur to Mooltan, constituting, with the Delhi Railway, the crown of that great railway system, 2200 miles in length, which will unite Calcutta in the Bay of Bengal with Kurrachee on the Arabian Sea. In the environs of Lahore are numerous gardens and wells, and since its occupation by the British it has very much advanced in commerce and wealth.

L'AIGLE. [ORNE.]

LAINÉZ. [JESUITS.]

LAING, MALCOLM, an historian, was born in Orkney, in 1762. He studied at Edinburgh, and in 1785 he joined the Scottish bar, but does not appear to have obtained much practice as a lawyer. His first known literary effort was editing the last volume of Henry's 'History of Britain,' in 1793, after the author's death. In 1800 he published 'The History of Scotland, from the Union of the Crowns, on the accession of James VI. to the throne of England, to the Union of the Kingdoms in the reign of Queen Anne,' accompanied by 'Two Dissertations, historical and critical, on the Gowrie Conspiracy, and on the supposed Authenticity of Ossian's Poems.' To the second edition of his History, published in 1804, he added 'A Preliminary Dissertation on the Participation of Mary, Queen of Scots, in the Murder of Darnley.' He was for some time member of Parliament for Orkney, and enjoyed the confidence and esteem of Fox. He died in 1818.

LAITY, persons not clergy; that is, the whole population except those who are in holy orders. All the lexicographers agree in deriving it from the Greek word *laos* (λαός), 'the people.' A *layman* is one of the laity. [CLERGY.] The word laity appears to have been first used in the second century, when the priests began to be looked upon as a separate class—intermediate between Christ and the people. The laity at first possessed great influence in the church, but it gradually declined, as the priests became more and more powerful, and in 502 they were forbidden to interfere in any affairs of the church whatever. The distinction has never been so marked in the Protestant as in the Roman Catholic Church.

LAKE, GERARD, first *Viscount Lake*, was born July 27, 1744. Having entered the army at the age of fourteen, and made his first campaigns in the Seven Years' War, he served in the American War, in Holland with the duke of York in 1793, and was appointed to the chief command in Ireland during the Rebellion of 1797-98. In 1800 he was sent as commander-in-chief to India, during the marquis of Wellesley's government. By a series of successes the whole of Scindia's possessions north of the river Chumbul fell into his hands; and in reward General Lake was raised to the peerage, September 1, 1804. In 1804-5, Lord Lake again took the field in the same part of India, against Holkar. He returned to England in September, 1807, and was created a Viscount, October 31. He died February 20, 1808.

LAKES are sheets of water of greater or less extent, surrounded on all sides by land, as islands are by water. They are distinguished from ponds by the fact that a lake is fed by streams either flowing at the surface of the soil or subterranean, while a pond, however large, is only the accumulation of rain-water in some hollow. Thus ponds are usually dried up in hot weather, while true lakes are only temporarily diminished by heat.

The principal difference in lakes is this:—1, Some have no apparent affluents nor outlets; 2, others have affluents without any visible outlet; 3, some have an outlet without any visible affluents; 4, others have both affluents and an outlet.

1. Lakes without apparent affluents or outlets are comparatively small, and yet they are, relatively speaking, more permanent than larger lakes, because, being fed chiefly by subterranean springs, they are not liable to be filled by those deposits of earth and sand which are the main cause of the rapid desiccation of such lakes as receive the troubled waters of torrents and rivers. Small lakes of this kind sometimes occur in hollows resembling the craters of extinct volcanoes.

2. Of lakes which receive affluents without having any visible outlet, the largest is the Caspian. The Aral and the Dead Sea are also examples of this kind of lake, which is very common in Asia. The excess of water brought into lakes that have no outlet is supposed to be carried off by evaporation, and in some cases perhaps by infiltration or subaqueous drainage also. Several of these lakes have formerly had outlets; but water has ceased to flow from them, because the lakes have sunk in consequence of receiving now a much smaller quantity of water than formerly.

3. Lakes that have an outlet without any apparent affluent are fed by subaqueous springs, which, bursting out in a hollow, must fill it up before the waters can flow off in a stream. These lakes are generally situated at considerable elevations above the level of the sea. Thus there is one on Monte Rotondo in Corsica, at an elevation of 9069 feet. From lakes of this kind some of the largest rivers take their rise; the Volga, for instance, springs from such a lake in the government of Tver in Russia.

4. Lakes which receive one or more tributary streams and have a visible outlet for their superabundant waters are the most common and the largest; such are the lakes of Geneva, Maggiore, Ladoga, Onega, Baikal, Superior, Huron, Erie, Ontario, &c.

Lakes differ very much in temperature, transparency, and in the colour of their waters. Those fed by the water of melted snows in summer are generally much colder than would be thought conformable with the season; but the difference is principally in the lower waters, which, being cold, remain at the bottom by reason of their greater density. Some never freeze, which is owing to their great depth.

The remarkable transparency of certain lakes is truly astonishing; thus the waters of Lake Superior and of the Norwegian lakes are so pellucid that fish, shells, and rocks may be seen at a depth incredible to persons who have never visited these regions. Elliot, in his 'Letters from the North of Europe,' says, 'Nothing appears more singular to a foreigner than the transparency of the waters of the Norwegian lakes. At the depth of 100 or 120 feet the surface of the ground beneath is perfectly visible; sometimes it may be seen wholly covered with shells, sometimes only sprinkled with them; now a submarine forest presents itself to view, and now a subaqueous mountain.'

With regard to the colour of lakes, it may be observed that it is sometimes very difficult to account for the tints of large masses of water. The colour of the bottom, the depth, the shadows and reflected colours of surrounding bodies, subaqueous vegetation, springs, and many other circumstances, affect the colour of lakes.

Lakes perform a very important function in the economy of the earth. Rain does not always fall; and, were it not for lakes, the greater number of rivers would be dried up in summer, and canals could not have a constant supply of water. The humidity which these sheets of water occasion by their evaporation is also eminently favourable to the vegetation in their environs.

LAKES are colours chiefly used by calico-printers and paper-stainers. They are made by mixing alumina with animal and vegetable colouring matters. Carmine or Florentine lake is prepared from a solution of cochineal. Lakes of many shades of red and purple are made from Brazil wood and madder root. Several yellow lakes are made from yellow-berries and arnotto; and almost every variety of animal or vegetable colour may be converted into a lake. Potash is sometimes used in the preparation to accelerate the precipitation, and regulate the colour.

LALANDE, JOSEPH JEROME LE FRANÇAIS DE, was born at Bourg in the department of Ain, July 11, 1732. When about thirteen or fourteen years old he was sent to a college at Lyons, where for a time he appears to have derived equal pleasure from the study of poetry and eloquence, and from attending the lectures of the several professors on natural and metaphysical philosophy. Upon the occurrence of the great eclipse of 1748, of which, with the assistance of his tutor, Le Père Béraud, he made a telescopic observation, he took great interest in the explanation given to him of that phenomenon, and thenceforward showed a more decided partiality for the mathematical sciences. In 1751 he was sent by the French Academy to Berlin to determine the moon's parallax—Lacaille being sent for the same purpose to the Cape of Good Hope. On his return he was made one of the astronomers royal, and in 1762

he succeeded Delille as professor of astronomy to the College of France. In 1764 he published his large treatise on astronomy, containing many very interesting biographical and historical notes. Lalande died at Paris, 4th April, 1807, in his seventy-fifth year. As an observer, an author, and a tutor, he undoubtedly did much for the promotion of astronomy; but looking to the state of mathematics at the time in which he lived, his knowledge of the exact sciences appears to have been very limited.

LAMA, LAMAISM, is the name given to the Buddhist religion in Mongolia and Tibet. Lama in these languages properly means 'priest.' The title is given to the head of every monastery, and every lama is considered a vicar of the Deity, and requires implicit obedience to all his commands, like the Dalai Lama himself. Much interesting information on Lamaism may be found in M. Huc's '*Souvenirs d'un Voyage dans la Tartarie, le Tibet, et la Chine*' (Paris 1852). He says that the lamas are the physicians of Tibet, and are supposed to cure by prayers and some insignificant medicaments. They are persons of the most limited information, and their faith is full of the grossest superstitions. Worship takes place three times a day, and consists chiefly of the recital of prayers and sacred texts, and the intonation of a hymn, accompanied with most inharmonious music. Offerings of tea, flour, milk, butter, and similar articles, are often made to the lamas or priests. Sacrifices of animals, or offerings entailing injury to life, are prohibited, as in the Buddhist faith. There are three great festivals in the year, and two sacraments—baptism and confirmation. Lamaism does not allow of the interment of the body after death; but the priests assert that it is necessary for them to be present at the moment of dissolution, so as to superintend the proper separation of the soul and body, and calm the spirit and enable it to be reborn in a happy existence. They also fix the day when it will be best to expose the body, for corpses are often placed on the tops of rocks to be the prey of beasts and birds. There are several orders of the clergy, all of whom are compelled to take the vow of celibacy, and many of whom live in monasteries. At the head of their faith is the Dalai Lama, who is never supposed to die, as his gifted soul is said to pass immediately to his successor. This favoured individual is believed to be indicated by the priests by certain signs, but the Chinese emperor, it is generally believed, really makes the selection. The residence of the Dalai Lama is at Lassa, the capital of Great Tibet, a city from which Europeans are carefully excluded. Huc reached it, but was at once conducted out of the country.

Perhaps the best work of reference yet published on Lamaism is *Die Lamaische Hierarchie und Kirche*, von Karl Friedrich Koepen (Berlin 1859).

LAMA, LLAMA, or GLAMA, the name of a species of the camel tribe peculiar to South America, where it is employed as a beast of burden, especially in crossing the Andes. It is very patient and docile, and will carry 125 lbs. at the rate of 15 miles a day. Its wool is used for similar purposes to that of the alpaca, but is inferior to it in quality.

LAMARCK, JEAN BAPTISTE PIERRE ANTOINE DE MONNET, CHEVALIER DE,

was born August 1, 1744, at Bazentin in Picardy, of a noble family. He devoted himself to science and formed a new classification of the plants in the Jardin du Roi, Paris, on a system formed upon the most easily reconciled theories of Jussieu and Linnaeus, and also on the older system of Tournefort. He named his work the '*Flore Française*.' It bears the date of 1778, and is in three vols., 8vo. In 1779 Lamarck was elected a member of the ancient Academy of Sciences. He had been appointed assistant to Daubenton in the Cabinet du Jardin du Roi, in 1788; and on the establishment of the Museum in 1793, he was appointed to the department which comprised the invertebrata. The '*Système des Animaux sans Vertèbres*,' published in 1801, was the fruit of his labours, and laid the foundation of his greater work, the '*Histoire Naturelle des Animaux sans Vertèbres*,' published at Paris from 1815 to 1822. His last work, the '*Mémoires sur les Coquilles*,' was published in the '*Annales du Muséum*.' He died in Paris in December, 1829.

LAMARTINE, ALPHONSE DE, an illustrious French poet, orator, and statesman, was born at Macon, in Burgundy, October 21, 1791. He had descended from a family which suffered much during the Reign of Terror, as described in after years in his '*Meditations of My Youth*.' After a very irregular education, he entered the army in 1814, but feeling weary of its inaction he quitted it two years later. It was in 1820 that he first became known as a poet, by his '*Meditations Poétiques*,' for which he had found great difficulty in getting a publisher. It was printed in the most modest form, but in a short time excited universal admiration, as it introduced a new and original style in the lyric poetry of France. The government recompensed Lamartine by appointing him secretary of embassy to Naples, where he met the young English lady, Miss Birch, who soon became his wife. He was afterwards sent to London in the same capacity, and thence transferred to Florence as chargé d'affaires. In 1823 appeared his '*Nouvelles Méditations*,' the sequel to the first; but it had by no means the success of its predecessor, in spite of the beauty of some of its pieces. On the publication of his '*Harmonies Poétiques et Religieuses*' (1829) he was elected a member of the French Academy. In 1832 he set out on a journey to the East, accompanied by his wife and only child—a daughter sixteen years of age, whom he had the misfortune to lose at Beyrout. The fruit of his travels was a work on the East, in imitation of Chateaubriand, which purported to treat of every subject—religion, history, philosophy, politics, poetry, &c. Owing chiefly to the numerous inaccuracies with regard to facts and negligence of composition, it had not the success which the writer and the public had anticipated. He was consoled, however, by the fact that during his absence he had been named deputy for Dunkirk. His first essay as a parliamentary speaker, on the discussion of the address (1834), was a decided failure. He made an elaborate speech, in which he treated of justice, morals, tolerance, &c., but passed over the question before the House. In 1835 he produced his poem of '*Jocelyn*,' which the public at first

received with hesitation, but which gradually attained a success as great as that of his first 'Meditations.' Two years later appeared 'La Chute d'un Ange'—an antediluvian episode of a great universal epic which he had planned, but which was received as coldly as his maiden speech or as his 'Voyage en Orient,' and for the same reason. In 1839 he published his 'Recueils Poétiques,' as the farewell of the poet to the muse. His literary labours did not, however, entirely detach Lamartine from politics; and though not a practical politician, he made considerable progress as an orator. In 1847 he published his 'Histoire des Girondins,' full of historical inaccuracies as usual, but written in the most attractive style. In this work he threw a sort of poetical halo round the actors in the most sanguinary events of the Revolution. The work proved immensely popular; parts of it were dramatized, and a new revolutionary hymn was prepared, when the revolution of February broke out. When the flight of the king left the field free, the popular voice called upon Lamartine to form part of the provisional government which soon proclaimed the Republic. Whatever may be thought of his influence in bringing about that revolution, and however severely he may be judged for the part he took in it, it is certain that the name of Lamartine, during the struggles which soon broke out between his colleagues, was regarded by the country at large as the symbol of order and moderation. During the confusion which followed, it was his eloquence that for several days protected the Hôtel de Ville when the provisional government was installed; and his courage, presence of mind, and energy saved Paris. There was a moment when he might easily have assumed the dictatorship; but his influence was of short continuance. The insurrection of June overthrew him and his colleagues, and at the general elections for the Legislative Assembly he was not returned. The *coup d'état* of 1851 put an end to his career in public, and he retired into private life.

His latter years were devoted to what has been well called the 'travaux forcés' of literature. His expensive tastes and his disregard or ignorance of the details of practical life had seriously compromised the fortune which he had inherited from his family, or which he had acquired by marriage; the political agitation in which he was engaged completed his ruin. He continued to send forth, fortnight after fortnight, his 'Entretiens,' and thus consumed in ephemeral productions the energies which he might have concentrated on the composition of a work more worthy of his fame. Offers of pecuniary assistance were more than once conveyed to him in the most delicate form by Napoleon III., but were declined until about two years before his death a bill was presented by the Government to the Legislative Chamber for an annuity of 25,000*fr.* to be paid out of the public funds, which was voted, and in this form relief was accepted by Lamartine. He died at Paris March 1, 1869.

LAMB. [SHEEP.]

LAMB, CHARLES, was born February 18, 1775, in Crown Office Row, Inner Temple, London. He was educated at Christ's Hospital; but labouring under an impediment of speech, which prevented his

succeeding to an exhibition in one of our universities, he became in 1792 a clerk in the accountant's office in the India House. Being unmarried, he dwelt through life with an only sister, whose occasional fits of insanity caused him continual anxiety, but who was only more endeared to him on account of her malady. The terrible ordeal through which he passed affected his own reason, but the attack was of short duration, and never returned.

Lamb's first appearance as an author was in a small volume of poems published jointly with Coleridge and Lloyd, in 1797, but which excited little attention. In the following year he published his prose tale of 'Rosamond Gray,' which sold better than his poems. His tragedy of 'John Woodvil' was completed in 1799, but it was never acted, and was not published till 1801, when it met with an unfavourable reception from the Edinburgh reviewers. In 1810 he became a contributor to a quarterly magazine entitled the *Reflector*, edited by Leigh Hunt; and some of Lamb's best effusions appeared in that short-lived periodical. On the establishment of the *London Magazine* in 1820, he began his 'Essays of Elia'—the name under the cover of which he acquired his most brilliant reputation. In the beginning of 1823 the 'Essays of Elia' were collected and published in a separate form, and met with a rapid sale. In 1825 he was permitted to retire from the drudgery of his clerkship with a liberal pension. His feelings on being emancipated from the desk, to which he had grown as it were until the wood had entered his soul, are beautifully depicted in his essay on 'The Superannuated Man.' But after the first enjoyment of freedom and uninterrupted leisure was over, he languished for want of steady employment, and discovered when too late that his happiness had not been promoted by the change. He occupied himself with occasional contributions to the *New Monthly*, the *Athenæum*, and other periodicals, and with assisting Hone in the preparation of his 'Every Day Book' and 'Table Talk.' A small volume of poems entitled 'Album Verses' appeared in 1830, and the 'Last Essays of Elia' in 1833. He died somewhat suddenly of erysipelas, 27th December, 1834, in the sixtieth year of his age. Mary Lamb, his sister, survived till 1847. In conjunction with her brother she wrote 'Mrs. Leicester's School,' 'Tales from Shakspeare,' and 'Poetry for Children.' The field which Lamb occupies is limited, but he reigns there supreme. He reflects every mood and touches every chord with a master hand. His works, like his conversation, exhibit by turns wit, humour, fun, quaintness, pathos, and varied fancy; and mingled with all is constantly seen the kindly, loving, honest, enjoying nature of the writer. It may be safely predicted that his incomparable 'Essays of Elia' will last as long as the English language. His letters to his distinguished friends Coleridge, Southey, Wordsworth, Bernard Barton, Manning, Procter, and other eminent writers, are among the happiest and the most delightful specimens of epistolary composition which the language affords. See 'Letters of Charles Lamb and Final Memorials,' by Judge Talfourd.

LAMBALLE. [CÔTES-DU-NORD.]

LAMBARDE, WILLIAM, the son of John Lambarde, an alderman of London, was born October

18, 1536. In 1556 he entered at Lincoln's Inn as a student. The first fruits of his studies appeared in a collection and translation of the Saxon laws, under the title of '*Αρχαιονομία*, sive de Priscis Anglorum Legibus Libri,' 4to, 1568. His '*Perambulation of Kent*' was published in 1576. In 1578 he was admitted a bencher of Lincoln's Inn, and in 1579 was appointed a justice of the peace for the county of Kent—an office which he explained in his '*Eirenarcha*, or the Office of the Justices of the Peace,' in four books, 4to, 1581. He also published a small treatise on '*The Duties of Constables*,' &c., 8vo, 1582. He died August 19, 1701. His '*Archeion*, or a Discourse upon the High Courts of Justice in England,' was not published till 1635. The materials which he had collected for a general account of Great Britain were published in 1730, in quarto, under the title of '*Dictionarium Angliæ Topographicum et Historicum*.'

LAMBERT, JOHANN HEINRICH, was born at Mühlhausen, August 29, 1728. He was sent to a school in the town, where he acquired the rudiments of a classical education; but the want of means obliged his father to withdraw him thence at an early age.

At home, however, the youth availed himself of every means in his power to preserve the knowledge he had acquired of the Latin tongue; and a great part of each night was spent in reading such of the Roman authors as he could procure, or in studying arithmetic and geometry. In 1749, on the recommendation of his patron, Dr. Iselin, he was appointed tutor to the children of M. de Salis, the president of the Swiss Confederacy; and while communicating instruction to his pupils, was enabled to study the Greek, Italian, and French languages, as well as to advance his knowledge of optics, astronomy, and philosophy.

In 1756 Lambert accompanied two of the sons of M. de Salis to the University of Göttingen; and after proceeding thence to Holland and France, he returned in 1758 to Coire. In 1763 he was employed as one of the commissioners in settling the boundaries between the territories of the Valais and the duchy of Milan; and in the following year, in consequence of an invitation from the king of Prussia, he proceeded to Berlin, where he passed the remainder of his life. He died September 25, 1777.

His great philosophical work, entitled '*Neues Organon*,' was published at Leipzig in 1764. This is divided into four parts, of which the first contains the rules of thinking, and the second is on truth considered in its elements; the third is on the external characters of truth; and the fourth, on the means of distinguishing the real from the apparent.

LAMBERT, JOHN, was born probably about 1620, and was educated for the bar. On the breaking out of the contest between the king and the Parliament, he joined the parliamentary army, and held the rank of colonel at the battle of Marston Moor (2nd of July, 1644). After distinguishing himself at Naseby, with Cromwell in Scotland, at Worcester, and on other occasions, and rising to the rank of major-general, the appointment of Fleetwood to the chief command of the forces in Ireland produced an alienation between Lambert and Cromwell which was never wholly healed, although he was one

of the officers whom Cromwell summoned in June, 1653, and was appointed in May, 1655, by the Protector one of his eleven major-generals. After the death of Cromwell he became the soul of the confederacy of discontented officers which was formed against the new protector, Richard. [CROMWELL, RICHARD.] On the breaking out of the Royalist insurrection in July, 1659, he was sent by the Rump Parliament to suppress it; but immediately after his success he turned round upon the Parliament, and on its resistance to his demands, dispersed it on October 13. At the beginning of January, 1660, having been deserted by the force with which he had set out for the north to encounter Monk, he was seized by orders of the restored Parliament, and committed to the Tower. On the 9th of April following he made his escape from confinement; but the activity of Colonel Ingoldsby recaptured him at Daventry on the 22nd of the same month. He was eventually banished to the island of Guernsey, where he lived for above thirty years.

LAMBESC. [BOUCHES-DU-RHÔNE.]

LAMBETH. [SURREY.]

LAMBOURN. [BERKSHIRE.]

LAMEGO. [BEYRA.]

LAMELLIBRANCHIATA, M. De Blainville's third order of *Acephalophora* (*Acéphales Testacés* of Cuvier). M. De Blainville divides this order into ten families, each family containing several genera. The families are—*Ostracea*, *Subostracea*, *Margaritacea*, *Mytilacea*, *Polydonta* or *Arcacea*, *Submytilacea*, *Chamacea*, *Conchacea*, *Pyloridia*, and *Adesmacea*. M. Rang's arrangement is different. He separates the order into two primary divisions—*Monomyaria* and *Dimyaria*, each having its respective families.

LAMELLICORNES (Latreille), one of the sections of the order *Coleoptera*, in which the antennæ of the insects are inserted in a small hollow in front of the eyes, and are usually composed of nine or ten joints, the last of which are large, flat, and open like a fan. Latreille divides the Lamellicornes into two great tribes, *Scarabæides* and *Lucanides*. (Cuvier, *Règne Animal*, vol. iv., p. 526.)

LAMELLIROSTRALES (Lat. *lamella*, 'a thin plate,' and *rostrum*, 'a beak'), a tribe of swimming birds, as the swan, goose, &c.

LAMENTATIONS, the name of the funeral music practised among the ancient Hebrews, whence, probably, the scriptural term, as applied to the Lamentations of Jeremiah. The *Lamentatrices* were the female vocal performers, who were hired to chant the lamentations over the dead, and to sing dirges of funerals, when they were accompanied with flutes.

LAMIA (Latin and Greek), a fabulous being which figures in many monstrous inventions of the ancient mythology, and has suggested to our English poet Keats a poem of great beauty. It is generally represented as a species of vampire with the power of assuming a woman's form. In the myth of Philemon and Machates, on which Goethe has founded his ballad of the 'Bride of Corinth,' a young man marries one of these lamias, who sucks his blood at night. The whole conception is grotesquely horrible.

LAMIA/CEÆ, or LABIATE, a very extensive and important natural order of exogenous plants. The species are generally aromatic and tonic—a pro-

perty which is in most cases owing to the secretion of a volatile oil in little cysts or glands occupying the leafy organs. The aromatic qualities are familiar to us in the Sage, Marjoram, Thyme, Basil, and similar plants, commonly cultivated for the service of the kitchen, as condiments; of Lavender, so much valued for its peculiar fragrance; of Mint and Peppermint, well known for their stimulating power, and of many others. Betony, Ground Ivy, Horehound, and others, are examples of the bitter tonic qualities of such plants.

LAM'MIUM, a genus of plants belonging to the natural order *Labiata*, which includes the Dead, Blind, and Dumb Nettles of our peasants, so called from their resemblance to the *Urtica* in many points, except their stings. *L. amplexicaule* is found in sandy and chalky fields in Great Britain, the North of Africa, and Middle Asia. *L. intermedium* is common in Scotland, Sweden, and the North of Germany. *L. purpureum* is found in Great Britain and Sweden, where, according to Linnæus, it is boiled and eaten. *L. incisum* is a British plant, and is likewise found in France, Germany, and Sweden. *L. album* was once used medicinally, but is now disregarded. This species is eaten in Sweden as a pot-herb. It is found in Great Britain and the southern parts of Europe.

There are several other species of Lamium, growing chiefly in the southern parts of Europe.

LAMLASH. [BUTESHIRE.]

LAMMAS DAY, the name for the first of August, from the Anglo-Saxon *Hlaf Messe*, Loaf Mass or Feast, when the Saxons offered an oblation of loaves made from new corn. Others derive it from a custom of bringing a lamb alive on this day into the church at High Mass. A term-day in Scotland.

LAMMERMUIR, or LAMMERMOOR HILLS, a range of mountains in Scotland, extending from the south-eastern extremity of the county of Edinburgh, through Haddington and Berwickshire, to the North Sea. Their surface is chiefly moorland and sheep-walks, though on the lower slopes are extensive tillage farms. The geological structure of this range consists of the lower silurian or grauwacke beds, with porphyry and granite rocks. The principal summits are—Sayrs Law, 1753 feet high; Whitestone Cairn, 1656 feet; and Lowrans Law, 1631 feet above the sea.

LAMP. [LIGHTS, ARTIFICIAL.]

LAMP-BLACK, a fine charcoal prepared from certain kinds of fir containing much resin, and the refuse and residuary resin left by the distillation of turpentine. The furnace chimney is long, and the greater part of it nearly horizontal, and its exit is covered with old sacking; or the smoke containing the charcoal is carried into chambers, where it is deposited on coarse cloths. The purest lamp-black is procured by the combustion of oils, but that is much too expensive for common use. Lamp-black is extensively employed as a black colour, and mixed with other pigments.

LAMP, SAFETY. It has been long known that coal mines, and especially such as are deep, are occasionally infested with carburetted hydrogen, known to the miners as *fire-damp*. Several contrivances were proposed for safely lighting coal mines subject to the visitations of this gas, but the safety-lamp

of Sir H. Davy was the first which was extensively employed.

Davy found that this gas requires an admixture of a large quantity of atmospheric air to render it explosive; that explosions of inflammable gases are incapable of being passed through long narrow metallic tubes; and that this principle of security is still obtained by diminishing their length and diameter at the same time, and likewise diminishing their length and increasing their number, so that a great number of small apertures will not pass explosion when their depth is equal to their diameter. This led to trials upon sieves made of wire gauze; and he found that, if a piece of wire gauze was held over the flame of a lamp, or of coal gas, it prevented the flame from passing; and he ascertained that a flame confined in a cylinder of very fine wire gauze did not explode even a mixture of oxygen and hydrogen, but that the gases burnt in it with great vivacity.

These experiments enabled Davy to determine the principles of a new safety-lamp. It consists of a cylinder of wire gauze, formed of iron wire about 1-50th of an inch in diameter, the meshes being about 1-24th of an inch. The wire cylinder is strongly jointed, and is defended by three upright strong wires, which meet at the top, and to them a ring is fixed, from which the instrument is suspended. The lamp is screwed on to the bottom of the wire gauze, and is supplied with oil by the pipe projecting from it, when the top is unscrewed and removed. A wire, bent at the upper end, is passed through the bottom of the lamp for raising, lowering, or trimming the wick.

When the lamp is lighted and introduced into an atmosphere gradually mixed with fire-damp, the first effect of the fire-damp is to increase the size and length of the flame. When the inflammable gas forms as much as 1-12th of the volume of the air, the cylinder becomes filled with a feeble blue flame, but the flame of the wick appears burning brightly within the blue flame; and the light of the wick continues till the fire-damp increases to one-sixth, or one-fifth, when it is lost in the flame of the fire-damp, which in this case fills the cylinder with a pretty strong light; and when the foul air constitutes one-third of the atmosphere, it is no longer fit for respiration.

The operation of the wire gauze in preventing the communication of flame is thus explained:—Flame is gaseous matter so intensely heated as to

be luminous, and the temperature requisite for producing it exceeds that of the white heat of solids. When the flame comes into contact with wire gauze, it loses so much heat in consequence of the conducting power of the metal which conveys it to the surrounding air, that it is cooled below the point at which gaseous matter can remain luminous, and consequently the flame of the gaseous matter burning within the lamp is incapable of passing through it so as to set fire to and explode the mixture of fire-damp and air by which it is surrounded; and this cooling power is exerted, even though the wire gauze, by effecting it, is rendered and remains red-hot.

Much discussion arose from time to time concerning the safety of this instrument: it was admitted that there were situations where it would not be danger-proof; but for a long time it was obliged to be confessed that no other invention was equal to it in respect to safety. In consequence of some very fatal explosions in collieries, committees were appointed by the Houses of Lords and Commons in 1849 and 1852 to consider the whole subject; and although in most cases it was shown that the accidents occurred in consequence of the miners not attending to the regulations with respect to the use of the Davy safety lamps, one of the results of the inquiries instituted by the committees was the introduction of several new safety lamps. In principle they are, of course, similar to the old Davy lamp, but differ somewhat in detail; some, for instance, have glass inside the wire gauze, some outside, and others dispense with the gauze altogether, and admit the air into a glass chimney, with a copper cone, through perforations in a metal bottom. Great difference of opinion exists as to the relative merits of the various lamps at present in use; but it is generally admitted that the gauze cylinder should be accompanied by one of glass, to resist the action of strong currents of air; and that the glass without the gauze is not sufficiently protected from fracture. As an historical fact in connection with the safety lamp, it may be stated that, in his 'Life of George Stephenson,' Mr. Smiles has sought to prove that, a year before Sir Humphrey Davy commenced his experiments on the subject, Stephenson was also employed in a similar manner, and so far succeeded that his lamps were for a long time used in Killingworth colliery, where he was at work as engine-wright at the time, and are still employed in several of the northern collieries.

LAMPETER. [CARDIGANSHIRE.]

LAMPIC ACID, a term given by Daniell to the acid which results from the slow combustion of alcoholic vapour and ether in the lamp without flame. It is acetic acid modified by the presence of a peculiar hydrocarbon.

LAMPREY. [PETROMYZON.]

LAMPYRIDÆ (*Lampyrus*, Linn.), a family of coleopterous insects of the section *Malacodermi*, in the great group of Latreille's *Serricornes*. To this family belong the genera *Lygus*, *Dictyoptera*, *Omalisus*, *Lampyrus*, and others. To the genus *Lampyrus* belongs the Glow-worm (*Lampyrus noctiluca*, Linn.). This insect is rather more than half an inch in length, of a blackish colour; the thorax is margined with dusky red, the legs and the edges of the segments of the body of the same colour. The female resembles the male, but is quite destitute of

wings, and the terminal segments of the abdomen beneath are yellowish; the thorax is semicircular; the body is very soft, of an oblong form, pointed at the extremity, and composed of ten segments. The male glow-worm is said to emit the phosphorescent light in a slight degree, but it is chiefly the female from which the brilliant light proceeds which we so often see on banks, beneath hedges, and in various other situations. This light proceeds from the under part of the abdomen and near the tip, and it appears that the animal has the power of varying its intensity. Glow-worms will live, we are informed by Latreille, a long time in vacuo, and in different kinds of gases; the nitrous acid, muriatic, and sulphurous gases excepted, for in these they soon expire. When placed in hydrogen gas, they sometimes detonate. If the luminous portion of the abdomen be removed, it retains its luminous property for some time, and when apparently extinct, it may be reproduced by softening the matter with water. The insects emit a brilliant light if immersed in warm water, but in cold water it is extinguished. The females being apterous, and consequently restricted in their powers of locomotion, and the insect being nocturnal, it is supposed that the light emitted by the female is for the purpose of attracting the other sex. The larvae may be kept alive for a considerable time; they feed voraciously upon snails, killing those of the largest size; sometimes they seize a snail whilst crawling, and when the animal retires within its shell, they still keep their hold, and allow themselves to be carried into the shell with the snail, and although they become enveloped in the mucous secretion, it very seldom appears to adhere to their bodies. Upon being touched or disturbed they emit the phosphoric light, but not to so great a degree as the perfect insect.

LANARKSHIRE, or CLYDESDALE, is an inland county of Scotland, bounded N. and N.W. by the shires of Stirling and Dumbarton, W. and S.W. by those of Renfrew and Ayr, E. and N.E. by those of Linlithgow, Edinburgh, and Peebles, and S. by Dumfriesshire. It is comprised between 55° 15' and 55° 56' N. lat., and between 3° 23' and 4° 23' W. long. The greatest length N. by W. to S. by E. is 52 miles; the greatest breadth E. to W. is 33 miles. The area is 889 square miles, or 568,867 acres, of which about five-twelfths are cultivated, and an equal quantity moorland. In 1861 the inhabitants numbered 631,566—304,151 males, and 327,415 females—being a large increase since 1851, when the population was 530,169. At last census there were 46,675 inhabited houses in the county. In 1868 it was officially estimated by the registrar-general that the population had further increased to 718,223.

The coal, iron, and lead mines of Lanarkshire are very extensive and rich—there being more than 150 collieries and thirteen or fourteen ironworks, with ninety blast furnaces, and all kinds of manufactures are carried on in and around Glasgow in the Lower Ward. Besides the fire-clay which there abounds, millstone, limestone, and slate are quarried in various parts of the county, and lead is found at Leadhills, combined with a little silver.

Lanarkshire is divided into three districts, named the Upper Ward, Middle Ward, and Lower Ward.

The Upper Ward, or southern part of the county, is covered by hills and mountains, of which the

highest elevations are about 2400 feet. On the summits of the hills and sides of the mountains are pastured numerous flocks of sheep, which, in the valleys, are intermingled with herds of black cattle. The Clyde and its tributaries, the Douglas, Avon, Calder, and several smaller rivers, have their sources in these mountains. [CLYDE.] The arable portion of this ward is inconsiderable, and chiefly on the banks of the Clyde and its tributaries. In this ward is the village of Leadhills, 1323 feet above the sea, and the highest inhabited place in Scotland. The lead mines here yield from 800 to 900 tons yearly. It was the birthplace of Allan Ramsay the poet, in 1685. There are also in this section of the county seams of excellent clay-band ironstone, limestone, coal, freestone, and slate, all of which are worked.

The Middle Ward is diversified by gently undulating grounds, there being no plains of any extent except in the valley along the banks of the Clyde. The prevailing soil is of a clayey nature, intermixed with sand. In some parts it consists of a deep fertile loam, resting upon a subsoil of loose gravel; in others it partakes more of a mossy character, and yields, in early seasons, good crops of oats, flax, and rye-grass hay, but in cold or late seasons the oats do not ripen well. Oats, barley, potatoes, and turnips form the principal crops, but there is also much wheat raised both in this and the adjoining ward to the north. This ward is peculiarly rich in a mineralogical point of view, containing, besides an abundance of limestone and sandstone, ironstone and coal; the latter almost of inexhaustible supply, and favourably situated. And in this ward, near Coatbridge, are placed the more extensive of the works for smelting iron. Works for the manufacture of wrought iron, tin-plates, tubes, shovels, &c., are rapidly increasing in this vicinity. The population of the parish of Old Monkland, in which Coatbridge is situated, under 10,000 in 1821, was in 1861 29,545, and in 1867 estimated at 35,000.

The Lower Ward, or northern part of the county, is of very limited extent, but as it contains the city of Glasgow, it is a very important one. There are immense fields of fire-clay, and the quality is considered fully equal to the Stourbridge clay. In their vicinity extensive works have been founded for the manufacture of crucibles, &c.; and there are extensive sandstone quarries and collieries, yielding coal and ironstone to a considerable extent. There is a considerable proportion of arable land, but the soil of some parts is moist and moorish. Many of the mosses have been reclaimed, and they are all gradually lessening by peat-cutting, so that oats, rye-grass, and even wheat, now grow luxuriantly where once the moor-fowl fed and the long heath waved. The wheat is sown from the end of August to the beginning of November, and sometimes, though very rarely, in spring.

Much of the land of this county belongs to large proprietors. The dairy system has been prosecuted with great success. The cows are mostly of the Ayrshire breed, and what are denominated Dunlop cheeses are largely made. The draught horses of Lanarkshire are held in great estimation in the north of England and throughout the south of Scotland.

The climate of the county is almost as various as its soil. The Lower Ward, being more open to the

sea breezes which prevail from the W. and S.W., is comparatively temperate. The climate in the Upper Ward is unusually severe.

In the Middle Ward the orchards formerly yielded fruit to the value of 8000*l.* a year, but have fallen off in latter years, partly because the ground is more profitably employed in producing vegetables for the Glasgow market, and partly because the facilities now afforded by steam navigation introduce large supplies of fruit from all producing districts both at home and abroad. For some miles below Lanark and the Falls of the Clyde, the river offers a picturesque succession of towns, villages, and plantations. Husbandry, though improving, is backward. The manufactures comprise cotton and muslins (which in prosperous times employ 40,000 to 50,000 hands), woollen, flax and silk goods, glass, paper, engines, ships, chemicals, and other articles, of which Glasgow is the great centre; with iron, at Glasgow, Shotts, Coatbridge, Wishaw, Lesmahagow, Monkland, Airdrie, &c.

The Forth and Clyde Canal, which connects these two rivers, throws branches into both Edinburgh and Glasgow. The Monkland Canal passes through the royalty of Glasgow, and affords a cheap communication between that city and the collieries and iron-works in the neighbourhood of Airdrie. The Ardrossan Canal, originally projected to connect Glasgow with Ardrossan, was never carried further than Johnston. Railways intersect the county in every direction.

Under the Reform Act of 1868 the county returns two members to Parliament, the city of Glasgow three, and the Falkirk district—including the boroughs of Lanark, Hamilton, Falkirk, Linlithgow, and Airdrie—one. The number of voters on the county register in 1869 was 7927—5134 in the north and 2793 in the south. Lanarkshire is divided into fifty-two parishes, and three presbyteries in the synod of Glasgow and Ayr.

The following are the principal places, with the population of each in 1861:—

Airdrie is a well-built town, 10 miles S.E. from Glasgow. It is contributory to the Falkirk parliamentary district. Population, 12,922. Registered electors, 439. It was created a borough by the Reform Act of 1832, and is governed by a provost, three bailies, and twelve councillors. It is a modern town, standing in the centre of the most productive beds of coal and ironstone in Scotland (from which its prosperity chiefly arises); and is surrounded by the Calder and other large iron-works. The chief public buildings are three churches, four chapels, prison, town-hall, gas-works, grammar-school, mechanics' institute, and four banks.

Blantyre is 8 miles S.E. of Glasgow, and has cotton-spinning and dye-works. Population of the parish, 3092. David Livingstone, the African traveller, was born here in 1817. It gives a barony to the Stewart family, who have a noble mansion at Erskine, on the bank of the Clyde. Ruins of an ancient priory are situated within the demesne.

Bothwell is a populous and extensive parish on the Clyde, 8½ miles S.E. of Glasgow. The inhabitants within the parish, which comprises altogether 13,774 acres, and includes the town of Bellshill (2945 population), number 17,903; within the little village of Bothwell itself, only 1057. In the parish are collieries, iron-works, and freestone quarries. Bothwell

Bridge, on the river, was the scene of an action between the covenanters and the royal forces in 1679, which Scott has depicted with graphic power in 'Old Mortality.' The castle is now a ruin, picturesquely situated on a wooded bluff above the river; the surrounding grounds forming a favourite resort for the Glasgow citizens. The church includes portions of the ancient Norman structure; the tower is 120 feet high. The manse was the birthplace of Joanna Baillie, the poetess.

Carlisle, a municipal borough, parish, and town, has manufactures of cotton, coal, iron, and lime-works. Population of parish (which comprises 15,410 acres), 6176; of town, 3111.

Coatbridge, a town in the parish of Old Monkland, 9½ miles E. of Glasgow, with which it is connected by two lines of railway and the Monkland Canal. It is surrounded by extensive iron-works and collieries; and contains several foundries and machine shops, with manufactories of tubes, tin plates, confectionery, shale oil, &c. The town is rapidly rising in importance, from its central position among the large neighbouring fields of coal and ironstone. Population, 10,501.

Glasgow. [GLASGOW.]

Govan, a rising town and parish to the S. and W. of Glasgow, of which it forms an extensive suburb, has extensive iron-shipbuilding yards and foundries. The entire parish (the greater portion of which lies within the parliamentary boundaries of Glasgow) contains 100,716 inhabitants; about one-fourth of it lies in the county of Renfrew. The river Clyde divides the parish at the point where it is joined by the Kelvin. The thriving town of Partick is included in its boundaries. The population of the town proper is 7637.

Hamilton, a handsome town, is pleasantly situated near the confluence of the Avon Water with the river Clyde, 11 miles S.S.E. from Glasgow. It is a parliamentary and municipal borough, and market town, and has a station on the Caledonian Railway. There is a five-arch bridge over the Clyde, and another over the Cadzow. The town is the head of a presbytery in the synod of Glasgow, and also the head-quarters of the county militia. The chief public buildings are two churches, one built by Adams, three chapels, a grammar-school, a trades' hall and new town-hall, market-house and old cross, cavalry and infantry barracks, race-stand, three hospitals, five branch banks, railway station, and one of the county prisons, &c. The borough was created by the Reform Act of 1832, and is municipally governed by a provost, two bailies, and twelve councillors. The whole parish comprises 14,400 acres, with a total population of 14,047. The inhabitants within the borough limits in 1861 numbered 10,688, including 177 military in barracks. The number of parliamentary and municipal voters is about 600. It is included in the Falkirk parliamentary district, which sends one member to the House of Commons. Hamilton was founded by, and derives its name from, the family of the Hamiltons, originally from Hambleton, in Leicestershire, who are now represented by the duke of Hamilton, the premier peer of Scotland, and hereditary keeper of Holyrood Palace. The peerage dates from 1445; the marquise having been created by James VI. in 1599, and the dukedom

in 1643. It has long been understood that to the title also belongs the dukedom of Chatelherault in France, but the claim was only confirmed by decree in 1864. Hamilton Palace, the family seat, is a very handsome Grecian structure, 264 feet long, and contains many valuable paintings and cabinets. The park in which it stands contains a magnificent mausoleum, erected a few years ago by Alexander the tenth duke, of which he became the first occupant, and a picturesque and striking copy of the façade of Chatelherault Castle. Cadzow Forest, which adjoins the park, is famous for its oaks, the last relics of the great Caledonian forest which once extended from sea to sea, as well as for a herd of the aboriginal breed of Caledonian wild cattle which is still preserved in it. The forest likewise contains the ruins of an ancient castle of the same name.

Lanark, the county town of Lanarkshire, is 31 miles S.E. by S. from Glasgow by the Caledonian Railway, and is situated nearly in the centre of the county. It is a place of great antiquity. The appearance of the town has been greatly improved of late years, and at present there are many handsome houses built of freestone. The chief public buildings are two churches, in a niche of one of which stands a colossal statue of the patriot Wallace, who lived here, three chapels, a grammar-school, with twenty-eight scholarships attached, a free school, library, militia barracks, court-house, and gaol; and three banks. This town is the chief polling-place for the county, and the borough is contributory to the Falkirk district. The number of the parliamentary and municipal constituency is about 300. The borough was chartered in 1310; and is governed by a provost, two bailies, and fifteen councillors. It is the head of a presbytery in the synod of Glasgow. The population of the parliamentary borough is 5047; of the royal borough, 5384; of the entire parish (10,560 acres), 7891.

Lanark stands on elevated ground near the east bank of the Clyde; and in its immediate neighbourhood are several Roman and feudal remains, and the celebrated Falls of the Clyde, consisting of Corra Linn, 84 feet high; Stonebyres, 80 feet; and Bonnington, 30 feet; all in the midst of picturesque scenery. Lanark occupies the site of *Colania*, which was built partly on the Watling Street and partly on the bank of the Clyde, now crossed by two bridges. There are also five on the Mouse Water, one of which, 128 feet high, was built by Telford, near Wallace's Cave and the Cartland Crag, which rise 400 feet above the bed of the stream. In 978 Kenneth II. assembled a parliament here.

New Lanark is a well-built village to the south of the town of Lanark, and on the east bank of the Clyde. Population, 1396, who are employed in weaving and cotton spinning. Here Robert Owen founded one of the earliest infant schools in Scotland; and his first attempts to establish a new system of social organization (1815-27) were made in this village, which owed its foundation to his father-in-law, David Dale, in 1783.

Rutherglen, 2½ miles S.E. from Glasgow by railway, is a parliamentary and royal borough, and joins with Kilmarnock and three others in sending one member to the House of Commons. There are about 180 voters in the borough, the population of

which is 8062; of the royal borough, 8071; of the entire parish, 9335. The borough was chartered by David I. in 1126, and is governed by a provost, two bailies, and eighteen councillors. Rutherglen, or 'Ruglen,' as it is called, is situated to the east of Glasgow, on the south bank of the Clyde; and comprises many good modern houses with an ancient parish church, and two other churches, four chapels, and a handsome town hall. It has also extensive print and dye works, collieries, and a paper manufactory. It is very ancient, and was formerly a very important place, Glasgow having been included within its municipal boundaries in the twelfth century; at present it consists chiefly of one well-paved street. Its former trade on the river has been absorbed by Glasgow, and its chief industrial resources are muslin weaving, and print, dye, and chemical works; but what may seem strange, it possesses an extensive and flourishing shipbuilding yard, whence iron steamships are continually issuing.

Shotts is a village and extensive parish (comprising 25,336 acres), 12 miles N.N.W. of Lanark. It has extensive coal and iron works. Population of the parish, 7343; of the village, named Shotts Iron Works, 1335.

Strathaven is a burgh of barony in the parish of Avondale, 14 miles S.E. of Glasgow. The population is 4085, who are mostly employed in weaving.

Wishaw, a town 5 miles N.W. of Carlisle, in the parish of Cambusnethan, having extensive coal-fields and iron works, is situate at the junction of a branch of the Caledonian with the Wishaw and Coltness Railway. Population, 6112.

Lanarkshire was the seat of the Damii, in Valentia. It was afterwards part of the British kingdom of Strath-Clwyd. Glasgow has an ancient cathedral, a building of great beauty, erected by Bishop John Achains, in 1133-36; Blantyre, remains of a priory. There are old churches at Biggar, Hamilton, and Bothwell; and castle ruins at Bothwell, Carnwath, Cadzow, Craignethan, Douglas, and Crawford, all on the Clyde.

LANCASHIRE, a north-western county of England, is bounded N. by Cumberland and Westmoreland, E. by Yorkshire (from which it is separated by the long ridge popularly called the backbone of England), S. by Cheshire, and W. by the Irish Sea. Its form is irregular, the county being narrow at the north, and gradually widening towards the south. The district of Furness, at the north-western extremity of Lancashire, is about 10 miles wide, and is separated from the rest of the county by the Bay of Morecambe, and by a narrow strip of the county of Westmoreland. The greatest length of Lancashire is about 75 miles, and its greatest breadth about 43 miles. The county is comprehended between 53° 20' and 54° 25' N. lat., and between 2° and 3° 15' W. long. The area is 1905 square miles, or 1,219,221 statute acres, of which about 850,000 are estimated to be arable, meadow, and pasture, the rest consisting either of wide ranges of mountains, or of great swamps, known by the name of mosses. The inhabitants in 1861 numbered 1,173,424 males, and 1,256,016 females: total, 2,429,440; being an increase of 398,204, or 20 per cent., over the number in 1851. Since 1801,

when the population was 673,486, the total increase has been 1,755,954, or 267 per cent. In 1868 it was estimated that the population of the county had further increased to 2,738,988.

Surface and Coast Line.—The inland part of Furness is an integral part of the Cumbrian range. Mountains rising to the elevation of between 2000 and 3000 feet are there separated by narrow valleys watered by brawling streams or occupied by lakes. The whole of the eastern side of Lancashire also consists of mountains or lofty hills, and an elevated chain runs through the centre of South Lancashire, rising to the height of more than 1500 feet, and approaching within about 10 miles of the sea. A fertile plain extends along the whole coast of Lancashire from the river Duddon, on the borders of Cumberland, to the estuary of the Mersey. This plain is not more than three or four miles wide at the northern extremity of the county, but it widens greatly in the lower part of the valleys of the Lune, the Wyre, and the Ribble; and in the valley of the Mersey it extends across the whole of South Lancashire. The principal Lancashire mountains are the Old Man or Maun (from an ancient British word, signifying a rock) of Conistone, 2577 feet; Pendle Hill, 1803 feet; Bleasdale Fell, 1709; Boulsworth Hill, 1698; Rivington Pike, 1545 feet. In the southern half of the county there are extensive sandbanks running for many miles along the coast, and visible at low water. Towards the north the coast forms a deep bay, of which Furness on the north and Rossall Point on the south form the extremities. This large bay is divided into the two smaller bays of Morecambe and Lancaster by a tongue of low land projecting near the mouth of the river Lune. Further south the estuaries of the Wyre, the Ribble, and the Mersey run far into the land. A large area of these bays and estuaries becomes dry at low water.

The only islands along the coast are off the southern extremity of Furness. Walney Island, the largest, extends from north-west to south-east about eight miles, in width nowhere more than one. The other islands of the group, Foulney, Pile of Foudrey, Sheep Island, Roe Island, Dora How, and Old Barrow, are all small.

Geological Character.—The uppermost formation is a bed of rich alluvium extending along the coast. This is in general very good land, but is in some places covered with peat moss. Next is the new red sandstone, composed of red or coloured rock, and covered in many places with thick beds of marl and earth. In the hollows of these marl beds there are extensive peat mosses, both in North and South Lancashire. Great quantities of large timber trees, the remains of ancient forests, are found in these mosses. The coal-field of South Lancashire comes next, covering a large portion of that division of the county, and forming the chief natural cause of its manufacturing pre-eminence. It occupies a large irregular tract between the Ribble and the Mersey of 400 square miles, and yields above 14,000,000 tons yearly. The pits are about 800 in number, and are scattered over the whole field, whose richest parts are in the neighbourhood of Manchester, Oldham, St. Helens, and Wigan. The millstone grit forms the heights which skirt the eastern side of the county. The valley of the Ribble and that of the Lune are

chiefly occupied by the carboniferous or mountain limestone, which rises into lofty hills and scaurs in the higher part of those two valleys. Furness is partly occupied by the last-mentioned rocks, and partly by slate-rocks of the Cumbrian system.

The most valuable mineral production of the county is coal. Its iron ores at Furness are amongst the richest in Great Britain, and are very extensively worked. Copper is also found in the neighbourhood of Coniston. Slate, flagstones, freestone, scythestones, brick clay, and furnace sand are also amongst the mineral products of the county.

Rivers and Lakes.—Most of the rivers that water this county have their general course from N.E. or E. to S.W. or S. Those of Furness flow from N. to S. The principal rivers are the Lune in the north, the Wyre and Ribble in the centre, and the Irwell and Mersey in the south.

The Lune rises in Langdale Fells and Shap Fells, in Westmoreland; it enters Lancashire below Kirkby Lonsdale, and flows through a beautiful and fertile valley and a wide estuary into Lancaster Bay. The length of its course is $53\frac{1}{2}$ miles, and it drains a basin or range of country extending over 434 square miles. It receives the Greta, the Wenning, and many small mountain streams, and is navigable for large vessels as high as Lancaster.

The Wyre rises among the fells or moorlands on the borders of Yorkshire, flows across the fertile district of the Fylde, and after passing Fleetwood enters the Irish Sea near Rossall Point through a wide estuary, which, however, narrows at the mouth. Its length is 27 miles.

The Ribble rises in the Yorkshire mountains, a little to the east of Whernside, enters Lancashire near Clitheroe, flows past Preston into a wide shallow estuary, and enters the Irish Sea. The length of its course is 61 miles, and it drains a district extending over 501 square miles. It receives the Hodder, Calder, Darwen, Roddlesworth, and Douglas in its course to the Irish Sea.

The Irwell rises above Bacup, in the highest part of Rossendale Forest, and flows through a most populous valley, abounding in manufacturing establishments, to Manchester. It affords water power to the towns of Bacup, Newchurch, and Bury, and receives the streams that flow through Bolton on one side, and Rochdale on the other. At Manchester the Irwell receives the Irk and the Medlock. There it turns to the west, flowing near Eccles and Barton-on-Irwell, and joins the Mersey at Lower Irlam, about 10 miles below Manchester.

The Mersey rises on the borders of Yorkshire, being formed by the union of the Etherow, which rises near the summit tunnel on the Manchester and Sheffield Railway, and the Goyt, which flows down from the highest part of the Cheshire hills. These two streams unite at a point named Water Meeting, near Cromptall. At Stockport the Mersey receives the waters of the Tame, which flows past Staleybridge and Ashton-under-Lyne to Stockport. The Mersey, which forms the boundary of the two counties of Lancaster and Chester, flows from Stockport through a very fertile country, running about four miles south of Manchester, to Warrington. About half-way between those two places it receives the Bollin on the south and the Irwell on the north. From

Warrington it flows to Runcorn, where the North-Western Railway crosses it by a magnificent bridge. Below Runcorn the Mersey expands into a spacious estuary, and empties its waters into the Irish Sea, three or four miles below Liverpool and Birkenhead. The estuary is 16 miles long, one to three miles wide, and is greatly obstructed by sandbanks in its upper part, though containing a wide expanse of deep water in the lower. Formerly the Mersey abounded in salmon, and was frequented by large shoals of herrings; it still teems with flounders, sparlings, conger-eels, and shrimps. The Mersey and Irwell are navigable from Liverpool to Manchester. Below Runcorn the former river receives the Weaver, a large stream that flows through the salt field of Cheshire. The Mersey is 68 miles in length, and, including the country drained by its numerous tributaries, is the outlet for a wide district, extending over an area of 1706 square miles.

There are several smaller streams in the county or its borders. Amongst these are the Duddon, the Leven, the Keir, the Yarrow, the Alt, and the streams known as Ditton Brook, Sankey Brook, and Grazebrook.

In Furness lie two considerable lakes, Winandermere or Windermere, and Coniston Water. Windermere, which belongs in part to Westmoreland, is about 11 miles long, and varies from 500 to 1700 yards in breadth. It is the largest lake in England, and its greatest depth is rather more than 200 feet. It receives the waters of many mountain streams, including those of the Bratley and Rothay, and also those of Esthwaite Water and a few small lakes and tarns: the united waters flow by the Leven into Morecambe Bay. The shores of this lake are in general beautifully wooded, especially on the western side, where the steep heights of Furness Fell rise from the lake clothed with a forest of larch and fir. In the centre of the lake is a group of small islands, the largest of which comprises 28 acres. Bowness, beautifully situated on the eastern side of Windermere, and Ambleside, at its northern extremity, are two of the most attractive places in the lake district; but the whole of the shores, both on the Lancashire and the Westmoreland sides of Windermere, are covered with beautiful villas and picturesque villages. Among the numerous varieties of fish found in this lake is the char, which is also an inhabitant of Coniston Water, and when potted is highly esteemed as a delicacy. Coniston Water is about six miles long, and rather less than one broad, with a maximum depth of 240 feet. Esthwaite Water is also a very pretty lake, situated amongst the mountains, and there are several other smaller lakes or tarns.

Canals and Railways.—The Sankey Canal was the first formed in Lancashire or in England. It originally extended only from the coal-field near St. Helens to the river Mersey at Sankey Bridge below Warrington, but it has since been carried along the north bank of the river Mersey to Widness Dock, opposite Runcorn, where many manufactories have been established, and a considerable town has grown up. The Bridgewater canals consist of a canal running from the Worsley collieries to Manchester; of a much more extensive one starting from the former, and running down the valley of the Mersey to Runcorn, thus forming, with the

estuary of the Mersey, a complete line of water communication from Manchester to Liverpool; and of a third canal from Worsley to Leigh, continued from Leigh to Wigan. Their whole length is about 36 miles, and they still bear traces of the genius of Brindley, as well as of the perseverance and self-sacrifice of Francis, duke of Bridgewater, who gave up the greater part of his life and nearly the whole of his income to the construction of these noble works. The first of these canals is connected with extensive tunnels and underground coal works at Worsley. The Leeds and Liverpool Canal, about 140 miles in length, extends from the port of Liverpool to the navigable river Aire at Leeds, and not only connects Liverpool and Leeds, but forms the greater part of a line of water communication extending from the Mersey to the Humber, traversing the coal-fields of Lancashire and Yorkshire near the towns of Ormskirk, Wigan, Blackburn, Accrington, Burnley, Colne, Keighley, Bingley, and Bradford. The Preston and Lancaster Canal commences at Preston, and runs northward to Lancaster, from which place it has been continued to Kendal. The Rochdale Canal commences near Manchester, and proceeds by way of Rochdale and Todmorden into the West Riding of Yorkshire, following the line of the river Calder, and joining that river near Halifax, from which point it is navigable to the Humber. The Ashton Canal also commences near Manchester, and runs to Ashton, throwing out branches to Stockport, to the Huddersfield Canal at Dukinfield, and to Oldham. It is also carried through the hills into Yorkshire, passing the town of Huddersfield, and joining the Calder near that town. The Peak Forest Canal connects the limestone quarries of Derbyshire with the manufacturing districts of Lancashire. The Manchester, Bolton, and Bury Canal runs from the river Irwell, up the valley of the Irwell, to Bury.

The first great passenger railway constructed in England was the Liverpool and Manchester, laid down by George Stephenson, and opened in the year 1830. This line now forms part of the immense undertaking of the London and North-Western Railway Company, which extends from London to Scotland, and is connected with Liverpool, Manchester, Warrington, Wigan, Preston, Lancaster, and numerous other important towns. The Lancashire and Yorkshire Railway also extends from Liverpool to Wigan, Bolton, Bury, Rochdale, and crosses into Yorkshire. The Manchester and Sheffield Railway extends from Liverpool, through Manchester, Sheffield, and Retford, to Grimsby, on the German Ocean. The East Lancashire extends from Liverpool to Preston, Blackburn, Burnley, Colne, into Yorkshire, where it unites with the principal Yorkshire lines. The North-Western line runs from Lancaster and Morecambe Bay up the valley of the Lune to Settle, and on to Skipton and Leeds. Recently a branch has been formed which crosses Morecambe Bay, and stretches to Ulverstone, Barrow, Broughton, and so on to Whitehaven and Workington. A line of railway runs from Preston to Fleetwood, with branches to Lytham and Blackpool. Southport is also connected with Liverpool, and with Wigan and Manchester, by the 'iron road.' In fact, there is not a town in Lancashire of any magnitude which is not united with

the whole system of railways throughout the county, and consequently with the railway system of the whole kingdom.

Climate and Agriculture.—The climate of Lancashire is mild in winter and moist in summer, owing to the vicinity of the Atlantic Ocean, but from the same cause it is exposed to frequent winds and occasional storms. The high hills which run along its eastern boundary shelter it from the cold easterly winds, but at the same time arrest the clouds that come from the Atlantic, and produce more abundant rains than occur in the eastern parts of England. The average rainfall is about 45 inches per annum, but in the wet season of 1852 it was very nearly 62 inches. In 1868, which was a remarkably dry season, it was not quite 35 inches.

Near the coast the land is generally level, and the soil consists of a deep alluvial earth, in some places covered with sand brought from the sea-shore by the westerly winds. The soil is very favourable for grass, roots, and garden vegetables. A fair quantity of wheat is grown, but oats are better suited both for the climate and soil. Potatoes are cultivated in the fields as well as in the gardens, and from the lightness of the soils, the abundance of manure, and the moistness of the climate, the crops are very abundant, and of excellent quality. Early potatoes are frequently raised, with crops of turnips after them in the same year. These are succeeded by wheat or barley and grass seeds. In the districts furthest from large towns, a four years' course of two green and two white crops is found to answer, but in the neighbourhood of the towns the land is chiefly in grass, oats, and potatoes. The hilly tracts are almost entirely laid out in grass, owing to the great demand for milk and butter. Most of the farms in the county are under 100 acres, though there are some of much greater extent both in North and South Lancashire. The cultivation of the whole county has greatly improved during the last thirty years. In that period nearly the whole of the land has been thoroughly drained, the fields have been enlarged by the removal of useless fences, and very good farm buildings have been erected on most of the large estates. Market gardening is carried on to a great extent around all the large towns, but especially in the neighbourhood of Liverpool, Manchester, and Warrington, and more than five thousand families are employed in garden cultivation.

The ancient breed of long-horned cattle is almost extinct in Lancashire, having given place, like nearly all the original breeds, to the short-horned or Durham, which gives twice as much milk and fattens in half the time. Comparatively few sheep are kept in the county, except in some of the thinly-peopled districts of the north. There is a great demand for powerful horses in the seaports and manufacturing towns, and much attention has recently been given to the rearing of horses and cattle.

Commerce and Manufactures.—Lancashire is the most important manufacturing county in England, monopolizing nearly the whole of the English cotton trade. Manchester is the capital of the cotton district. That trade is also carried on on a very large scale at Bolton, Blackburn, Preston, Burnley, Accrington, Haslingden, Bacup, Bury, Rochdale, Todmorden, Oldham, Ashton-under-Lyne, and in numerous other

towns and populous villages. The number of persons employed in the cotton trade at the present time is about 400,000, and their united labours are estimated at 80,000,000*l.*, about two-thirds of which are exported. The silk, woollen, and flax manufactures are also carried on, though not on so extensive a scale as that of cotton. Many other branches of industry are pursued in the county. Amongst these are mining, engineering of every description, shipbuilding (both iron and wood), iron and brass manufactures, hat factories, plate-glass, bottle, and pottery works, alkali, soap, and chemical works, pin manufactures, watch-movement manufactures, and the manufacturing of all kinds of tools and implements.

The commerce of Lancashire is as vast as its manufactures. One-half of the merchandise exported from the United Kingdom is shipped from the port of Liverpool. In the year 1867 the aggregate value of British exports amounted to 180,961,923*l.*, to which Liverpool contributed 76,101,118*l.* The exports of Liverpool in 1868 amounted to about 78,000,000*l.* The imports are also on a gigantic scale, cotton, grain, and timber being amongst the most important articles. The value of the cotton imported into Liverpool has for some years varied from 30,000,000*l.* to 50,000,000*l.*, according to the fluctuations in the price of that article. [LIVERPOOL.]

Divisions and Towns.—Lancashire is divided into the six hundreds of West Derby, Salford, Blackburn, Leyland, Amounderness, and Lonsdale. It contains forty-eight towns, the smallest of them containing 2000 inhabitants. In the year 1867, according to the estimate of the registrar-general, the town of Liverpool contained 492,439 inhabitants, that of Manchester 362,823 inhabitants, and that of Salford, which is only separated from Manchester by a narrow stream, 115,013 inhabitants. After London, these are the largest communities in England. The county contains sixty-nine whole parishes, parts of four others, 452 chapelries and townships, twenty-six poor-law unions, and twenty-five county courts. It includes parts of the dioceses of Manchester and Chester, is in the province of York, and in the northern circuit. The assizes for the northern division of the county are held at Lancaster; for the southern division, at Liverpool and Manchester. For parliamentary purposes the county is divided, by the Reform Act of 1867, into North, North-east, South-east, and South-west Lancashire, each division returning two members. Liverpool and Manchester return three members each; Blackburn, Bolton, Oldham, Preston, Salford, and Wigan two each; and Ashton-under-Lyne, Burnley, Bury, Clitheroe, Rochdale, Staleybridge, and Warrington one each; total, thirty-three. Before the Reform Bill the number was twenty-seven only; the new members are, three to the county, one each to Liverpool and Manchester, and one each to Salford, Burnley, and Staleybridge. Lancaster was disfranchised for bribery at the election of 1865. The places of election are Lancaster, Blackburn, Manchester and Liverpool.

The following are the principal places, with the population of each in 1861:—

Accrington is a town and township 5 miles E. from Blackburn, situated on the Leeds and Liverpool Canal and the East Lancashire Railway. It is in the neighbourhood of numerous coal-pits, and

contains extensive cotton factories. It has a total population in the new and old towns of 13,872.

Ashton-under-Lyne. [ASHTON-UNDER-LYNE.]

Ashton-in-Mackerfield is on the road between Warrington and Wigan, 3 miles N.N.W. from Newton, and about 17 miles N.E. by E. from Liverpool. There are numerous collieries in the parish, which also contains much good land. The population of the parish is 10,181; of the town, 6566.

Bacup, a prosperous town on the Irwell, 15 miles N. of Manchester, containing numerous churches, cotton factories, dye-works, brass and iron foundries, a mechanics' institute, and a beautiful market-hall opened in 1867. It is surrounded by coal mines. Population, 10,935.

Barrow-in-Furness, a rapidly increasing town and municipal borough of 18,500 inhabitants, situated at the extreme point of the promontory of Furness. In 1847 the population was only 325, and its rapid progress is due to the iron-works, where more than 600,000 tons of iron are annually produced. The town obtained a charter of incorporation in 1867, when docks rivaling those of Birkenhead in extent and position were commenced at an estimated cost of 300,000*l.* In this scheme Barrow Island is made available for shipbuilding yards; an outer island, Walney, acting as a natural breakwater. The tide-way between the island and the mainland is inclosed, and converted into floating docks.

Blackburn. [BLACKBURN.]

Blackpool is a much frequented sea-bathing place, situated on a lofty bank on the coast of the Irish Sea, 18 miles W.N.W. from Preston, and 27 miles S.W. from Lancaster. A very handsome pier, which cost 20,000*l.*, was opened in 1868. The town has of late years much increased, and upwards of 100,000 visitors now arrive annually. Population 3506.

Blackrod, an ancient manufacturing town, 7 miles S.S.W. from Bolton. There are numerous coal-pits in the neighbourhood. Population, 2911.

Bolton. [BOLTON.]

Burnley, a municipal and parliamentary borough, 25 miles N. of Manchester, is situated on the banks of the Burn, near the confluence of that river with the Calder. The greater part of the town is of recent erection, and is well built of freestone found in the neighbourhood. Both the cotton and the woollen manufactures are carried on extensively. The Leeds and Liverpool Canal, which nearly surrounds the town, opens a communication for the conveyance of goods through the whole line of country from the German Ocean to the Irish Sea. Coal and slate are abundant. There are also manufactures of machinery, iron and brass foundries, breweries, tanneries, and rope-walks. The industrial prosperity of this town, which is chiefly owing to its water power and the abundant supplies of coal in the vicinity, has been greatly promoted by the Leeds and Liverpool Canal, already noticed, and by the easy railway communication with Blackburn, Bury, Manchester, and Liverpool. The parish church is a mixture of various styles of architecture, having been rebuilt and enlarged several times. A free grammar-school has existed in the town since the Reformation. It is well endowed. Burnley was created a parliamentary borough by the Reform Act of 1867, and the number of voters in 1869 was 5514. Population, 28,700.

Bury. [BURY.]

Cartmel is about 13 miles N.W. from Lancaster, with which it is connected by the railway that now crosses the sands of Morecambe Bay. The town is situated in a narrow vale watered by a small stream, and overhung on the east by the high ridge of Hampsfield Fell. The streets are narrow and irregular. The houses are principally built of stone. The church, which formerly belonged to a priory, was purchased at the dissolution of religious houses, in 1539, by the inhabitants, and afterwards made parochial. It is a large, handsome, cruciform building in the early English style, with a central tower. Cartmel is the chief place of a rich agricultural district. There are cotton mills in the neighbourhood, but the trade is not extensive. Population of the parish, 5108.

Chorley is a market town 9 miles S.E. from Preston, and 11 miles N.W. from Bolton, with both of which it communicates by railway. The town stands on a hill, the base of which is watered by the Chor, a rivulet that flows into the Yarrow about a mile below the town. The streets are wide and well built, and the town is well supplied with water. The chief articles of manufacture are calicoes, muslins, ginghams, and fancy goods. In the neighbourhood are extensive coal mines, with slate and stone quarries, and a little lead. The Leeds and Liverpool Canal passes within a mile E. of the town. The parish church is for the most part of Norman architecture, and there is also a modern Gothic church, as well as a Roman Catholic chapel, and places of worship of various denominations of dissenters, a grammar-school, and union workhouse. The population of the parish is 15,013.

Clitheroe, a market town and municipal and parliamentary borough, 30 miles N.N.W. from Manchester by railway. There is a moot hall (a modern building of the Gothic order), a gaol, and a bank. Clitheroe Castle, built on a steep rock, in 1178, by Robert de Lacy, to whom the honour of Clitheroe, which comprised the whole hundred of Blackburn, was granted, was dismantled by the parliamentary commissioners in 1649, and is now nearly demolished, the keep only remaining. The present church is an ancient structure, with a fine Saxon arch between the nave and choir. There is also a chapel of ease, a Roman Catholic chapel, two other chapels for dissenters, and a free grammar-school, founded by Queen Mary in 1554. There is no coal in the neighbourhood, but the river Ribble and smaller streams furnish water power in abundance. Cotton printing, bleaching, and the cotton manufacture are carried on to a considerable extent. The town is built of stone and the streets are well paved. The municipal borough is governed by four aldermen and twelve councillors. Clitheroe is very pleasantly situated in a grassy vale, and on the banks of the Ribble at the base of Pendle Hill (which rises 1803 feet above the sea), from which there are extensive prospects. It is a clean town, and communicates by railway with extensive limestone quarries at Chadburn, as well as with Whalley, Blackburn, Accrington, Preston, &c. Print, paper, and lime works are established here.

Under the Reform Act of 1832, which deprived it of one of its two members, Clitheroe returns one

representative to Parliament. The number of electors in 1869 was 1595. The population of the parliamentary borough in 1867 was 10,569; of the municipal borough in 1861, 7000.

Cole, a market town 18 miles N.E. from Blackburn, and 31 miles from Manchester. It is a station on the East Lancashire Railway. The town stands on a tongue of land formed by a small stream and the Leeds and Liverpool Canal. The church is an ancient building. There are two chapels of ease, a grammar-school, cloth hall, and manufactures of cotton, calico, mousselines de laine, and wool. The mills are partly turned by water power. The neighbourhood yields coal, slate, and freestone. Population, 7906.

Dalton, a small town in the Furness iron district, is 5 miles S.W. from Ulverstone. The town consists of a principal street, which terminates in a spacious market-place. The church is a small neat building of considerable antiquity. Iron mines, yielding ore of extraordinary richness, are found at many places in the neighbourhood. There is also a considerable trade in malting, the neighbourhood producing excellent barley. Population of the parish, which includes several islands on the coast, 9152; of the town, 2812.

Droylsden, a manufacturing town rising rapidly into importance, and situated on the railway in the neighbourhood of Ashton-under-Lyne, contains 5980 inhabitants.

Farnworth, a rising manufacturing town on the banks of the river Irwell, between Bolton and Manchester, contains 8720 inhabitants.

Fleetwood-on-Wyre, a seaport and watering-place 18 miles N.W. from Preston, with which it is connected by a railway. It stands at the mouth of the estuary of the Wyre. The town, harbour, docks, warehouses, and pier were planned by Sir Hesketh Fleetwood, Bart., about the year 1836, on ground which before that time was little else than a rabbit warren. A large hotel, shore lighthouses, and other buildings have been erected, and docks and additional works constructed with the assistance of the London and North Western, and the Lancashire and Yorkshire Railway companies. It was expected that Fleetwood would attract a large amount of foreign trade, as well as of the traffic to and from Belfast, Londonderry, Drogheda, and other Irish ports, and to and from Glasgow and Ardrossan; but Liverpool still commands nearly all the foreign trade and most of the Irish traffic, while the opening of the Caledonian Railway has seriously interfered with the development of the trade between Fleetwood and the Scottish ports. The population of the township of Thornton, in which Fleetwood is included, is 5084; that of Fleetwood itself, 3834. A school of musketry has recently been established, which promises to make it the Hythe of the north of England. There are several steamers to and from Ireland and Scotland. The total number of entries at the port in 1867 was 717 (176,234 tons), and the clearances 547 (154,976 tons). The customs revenue in 1868 was 935*l*.

Garstang, a market town, is 11 miles S. from Lancaster. It is a station on the Preston and Lancaster Railway. The streets are irregular, but are well paved and lighted. The parish church is about a mile and a half from the town. The Preston and

Lancaster Canal crosses the Wyre by an aqueduct close to the town. There are cotton and worsted mills, and calico printing establishments in the neighbourhood. Population of the township, 714; of the entire parish (which covers 31,403 acres) 7221. Garstang has petty sessions, and is the head of a poor-law union.

Haslingden, a market town and chapelry in the parish of Whalley, on the East Lancashire Railway, is 8 miles N. of Bury, and 18 miles N. by W. from Manchester. It is the highest town in England, being nearly 1000 feet above the level of the sea, and is situate in a wild Alpine district, abounding in coal, stone, and water power. The older part of the town, including the church, lies on the declivity of a hill. The town is prosperous and improving, and contains several new factories and other buildings. Cotton is the staple manufacture, but the woollen manufacture is also carried on extensively. There is a church, and several places of worship for dissenters. Population of the township, 6929; of the entire parish, 10,109.

Hawkshead, a small market town 29 miles N.N.W. from Lancaster, is situate on the west side of Windermere, near Eastwaite Water. The church is an ancient structure, and there is an endowed grammar-school. Population of the township, 1144; of the parish, 2081. This is the capital of Higher Furness.

Heywood, a rising town on the Lancashire and Yorkshire Railway, 8 miles N.W. of Manchester. The inhabitants, who number 12,824, are principally engaged in the cotton manufacture.

Kirkham, a market town in the Fylde, 9 miles W.N.W. from Preston, is the chief place in a rich agricultural district. The Preston and Lancaster Canal passes near it; there is also a branch railway to it from the Preston and Wyre Railway. It is small, but neat and well built. The church was rebuilt in 1822; but the ancient tower of Norman architecture remains. There are a free grammar-school, a Roman Catholic chapel, and several well-endowed charities and schools. Sail-cloth, sacking, cordage, flax, and cotton are manufactured here. Population of the parish, 11,445; of township, 3380.

Lancaster, a municipal and former parliamentary borough, and river port, the capital of the county, was once a Roman station, and a city of great antiquity, is distant 240 miles from London by road, or 232 by the North-Western Railway, and has railway communication with all parts of the kingdom. The town is called *Lancastre* in the Domesday Survey. It is pleasantly situated on rising ground on the south side of the river Lune, about 6 miles from the mouth of the estuary in Lancaster Bay. The Lune is crossed by a handsome bridge on five arches, and by a viaduct and aqueduct for the railway and canal. The houses are built of stone, and in general the streets are narrow; but the new streets towards Skerton are large and handsome, and there are many fine villas in the neighbourhood. The town is paved, lighted, and well supplied with water. On the highest point of land stands the castle, built before the Conquest, but greatly enlarged in the reign of Edward III. The view from John of Gaunt's round tower is magnificent. This castle was the head of a duchy palatine created for John of Gaunt, 'time-honoured Lancaster,' with a separate

court, and jurisdiction over the vast estates which then belonged to the duchy of Lancaster in all parts of England. The other principal public buildings are St. Mary's Gothic church, near the castle, built on the site of an ancient priory; five other churches, including new St. Peter's, with a spire of 245 feet; eight chapels; county courts; shire-hall and county gaol within the castle walls, which stretch about 380 feet by 350, with the statue of George III. in the centre; theatre, town-hall and exchange, market, custom-house, music-hall, Oddfellows' hall, assembly rooms, savings' bank, mechanics' institute, dispensary, barracks, baths; ancient free grammar-schools, rebuilt 1853, blue coat, national, and other schools; Mrs. Ripley's hospital for 300 children, founded in 1853, in the Gothic style; and a union workhouse. There is also an extensive lunatic asylum for the county on the moor above the town, and a beautiful cemetery of 21 acres is laid out in a very fine position. There are several almshouses, and an establishment for promoting the fine arts. The manufactures are of cotton, silk, linen, table baize, worsted yarn, cabinet manufacture, sail-cloth, rope, twine. There are salmon fisheries in the Lune, and ship-building is carried on to some extent. The principal quay and dock are at Glasson, 5 miles below the town, but vessels of moderate size can come up the Lune. Port Morecambe, a terminus of the Midland Railway Company, and a place of embarkation for Belfast, and where a very fine pier has been erected, is also very near to Lancaster. The chief articles imported into Lancaster are sugar, coffee, rum, mahogany, dyewood, &c. The number of vessels that entered the port in 1867 was 1400 (196,467 tons), and the clearances 2093 (266,401 tons). The customs revenue in 1868 amounted to 12,468*l*. The spring and summer assizes for the northern division of Lancashire, and courts of quarter session, are held at Lancaster, which is a polling-place for the northern division of the county, and the seat of a county court. The municipal borough is divided into three wards, and is governed by six aldermen and eighteen councillors. Population, 14,487; and of the entire parish, 27,430. The town returned two members to the House of Commons from 1295 to 1865 when it was disfranchised for bribery.

Leigh is near the Bolton and Liverpool Railway, and on the line from Kenyon Junction to Manchester. The townspeople are engaged in the manufacture of silks, muslins, cambrics, and fustians. There are very extensive collieries and stone quarries in the parish, and a large foundry for agricultural implements. A grammar-school and other charities are supported in the town. Leigh communicates with Manchester by the duke of Bridgewater's Canal, and with the Leeds and Liverpool Canal by a branch to Wigan. Population of the parish, 30,052; of the township, 10,621.

Liverpool. [LIVERPOOL.]

Lytham, a pleasantly situated watering-place, on the north bank of the Ribble, 5½ miles W.S.W. of Kirkham, with a branch railway joining the Preston and Wyre Railway, lies in a remarkably well cultivated district. It is frequented for sea-bathing, and a handsome pier has recently been erected for the accommodation of visitors. Population, 3194; of town, 2556.

Manchester. [MANCHESTER.]

Middleton is $6\frac{1}{2}$ miles N. by E. from Manchester, near the river Irk, which flows into the Irwell at Manchester. This town owes its prosperity to the cotton and silk manufactures. The church is an ancient building, with a carved screen dividing the chancel from the choir. There are several dissenting places of worship and a grammar-school. Population of the parish, 19,635; of the town, 9876. Middleton is on the line of the Rochdale Canal, and the Manchester and Leeds Railway. Coal mines are worked in the neighbourhood.

Newchurch (in Rossendale), is a chapelry in the parish of Whalley, 6 miles S.S.W. of Burnley. It has an endowed school. The inhabitants, who are employed in cotton and woollen factories, coal mines, and quarries, number altogether 24,413; but this includes an extensive district, the population of Newchurch town being only 3115.

Newton in Mackerfield, a pleasantly situated town 5 miles from Warrington, and half-way between Liverpool and Manchester, has a station on the Liverpool and Manchester Railway, and was an ancient parliamentary borough, disfranchised by the Reform Act of 1832. It is still the place of election for the southern division of the county. It consists chiefly of one street, and has an ancient court-house, now used for a school. Valuable beds of coal have been found in the neighbourhood, and manufactures of various kinds are springing up. The town has engine factories, with manufactures of fustian and glass. Population, 5909.

Oldham, a parliamentary and municipal borough, and flourishing manufacturing town, is 6 miles N.E. of Manchester. The town is situated at the foot of the lofty hills leading into Yorkshire, from which a branch of the Medlock flows past the town. Its rapid rise is chiefly attributable to its being in the immediate neighbourhood of extensive coal mines (which give employment to a large portion of the population), and also to the great increase of cotton manufactures. The manufactures of fustians, velvets, cords, cotton, woollen, and silk goods is very extensive. It possesses some of the largest mills in the kingdom—upwards of two hundred altogether. Various improvements have been effected of late years in the town. Oldham has a Gothic parish church, six district churches; twelve Methodist, five Independent, one Unitarian, and one Roman Catholic chapel; a Friends' meeting-house; town-hall, in the Grecian style, including assembly rooms, post office, &c.; gas and water works; public baths, working men's and temperance halls; three banks; public library or lyceum (1856), several literary institutions, a free park, the largest in the county—upwards of 60 acres. The educational establishments comprise Harshaw's blue-coat school (founded in 1807 and opened in 1834), Assheton's free grammar, and many Sunday and other schools. Oldham has a union poorhouse, and two public cemeteries containing 46 acres. Mill machinery is extensively constructed by Messrs. Platt Brothers & Co., at the Hartford works, the largest in the world, employing from 6000 to 7000 hands. Oldham is divided into above town and below town, and is in the parish of Prestwich. It has excellent railway communication with Manchester, Ashton-under-Lyne, Staleybridge, Saddleworth, and Rochdale, and from those places with all

parts of the kingdom. It is a polling-place for the south-eastern division of the county, and petty sessions and county courts are held. It was created a borough by the Reform Act of 1832, and sends two members to the House of Commons; the number of voters in 1869 being 13,454. The municipal borough is divided into eight wards, and governed by a mayor (who is returning officer), eight aldermen, and twenty-four councillors. Population of the parliamentary borough, 110,000, within the municipal limits, 72,333.

Ormskirk is 73 miles N. by E. from Liverpool, near the Leeds and Liverpool Canal, and with a station on the East Lancashire Railway. It has a town-hall, grammar-school, almshouses, and other charities, and consists of four principal streets, which intersect each other at right angles. The church is mostly modern, with a few portions of late perpendicular character. Cotton and linen thread, silks, hats, and rope are manufactured here. In the vicinity are large collieries. Population of the township, 6426; of the parish, 17,049.

Poulton is about 17 miles in a straight line S.S.W. from Lancaster, and is one of the principal towns in the Fylde. The Preston and Wyre Railway passes through it. The town is about a mile from the estuary of the Wyre. Population of the parish, 8665.

Prescot is 8 miles from Liverpool, with which it is connected by a branch of the North-Western Railway. There are extensive collieries in the parish, and a few cotton and flax mills. Among the principal manufactures of the town are small files, and the movements and other parts of watches. The church is ancient and large. Population of the parish, 63,540; of the township, only 6066.

Preston. [PRESTON.]

Rochdale, a parliamentary and municipal borough, 11 miles N.N.E. of Manchester. It is the principal station on the Lancashire and Yorkshire Railway, and has railway communication southward to Manchester, Oldham, and Ashton. The parish is of very great extent, and reaches into the West Riding of Yorkshire. The town is situated on both sides of the river Roche, a tributary of the Irwell, and the different portions of the town are united by three bridges. The streets are for the most part irregularly laid out, but well paved and lighted, and have been considerably improved of late years. The town is abundantly supplied with water. The parish church, a large old edifice, partly in the early English style, has a few remains of Norman character in the interior. The principal public buildings are the vicarage, on an eminence ascended by 123 steps; five other town churches, exclusive of twelve more within the parish bounds; ten chapels; town-hall and market-house; New Bailey prison; news room; theatre; assembly room; barracks; savings' bank; three other banks; 160 mills and factories; Archbishop Parker's free grammar-school; Hardman's and other free schools; and union workhouses. The manufactures are of very great importance; that of wool has existed from very early times, and is said to have been improved by some Flemings who settled there in the time of Edward III. About 10,000 hands are employed in cotton factories and print works; and 6000 in the baize, flannel, carpet, and other woollen factories, which are distributed in every accessible part of the town and on the neighbouring heights.

Hats and machinery are also made here. At Littleborough, by which a Roman way formerly ran, are the tunnels of the railway and the Rochdale Canal, whose summit levels are respectively between 500 and 600 feet above the sea-level. Lines of railway connect Rochdale with Manchester, Bury, Todmorden, Halifax, Leeds, and Burnley. Coal, slates, flagstone, and freestone are found abundantly in this parish, and steam power and water power extensively employed. The Rochdale Canal, which passes near the town, uniting westward with the duke of Bridgewater's Canal, and eastward with the Calder and Ribble navigation, 33 miles in length, cost upwards of 600,000*l.*, and is supplied by large reservoirs, one of which covers 130 acres. Rochdale returns one member to Parliament; the number of voters being 1358. By a charter dated 1856 it was made a municipal borough, under the jurisdiction of a mayor, ten aldermen, and thirty councillors. Petty sessions and county courts are held in Rochdale, which is a polling-place for the southern division of Lancashire, and the head of a poor-law union. The boundaries of the present borough were defined by an Act of 16 & 17 Vict. to comprise a circle of 3 miles' radius from the market-place near the old bridge, and include, beside the town of Rochdale, Castleton, Spotland, Wardleworth, and Wuerdale-with-Wardle. The late Richard Cobden, the 'Free Trade Apostle,' represented Rochdale in Parliament for several years. The population within the municipal limits is 38,114; within the parliamentary bounds 43,668; of the entire parish (comprising a part of Yorkshire), 119,531; of the Lancashire portion of the parish, 100,990. The number of voters in 1869 was 8728.

Salford. [SALFORD.]

St. Helens, one of the most flourishing towns of Lancashire, is 11½ miles from Liverpool by the Liverpool and Manchester Branch of the London and North-Western Railway. It is situated on one of the richest portions of the Lancashire coal-field, and owes its rapid progress chiefly to that circumstance. The Sankey Canal, extending from this town to the river Mersey at Sankey Bridge, near Warrington, has rendered the St. Helens coal-field one principal means of supplying coal to the port of Liverpool, and to the salt-field of Cheshire.

A great impulse was given to the prosperity of St. Helens by the establishment of the British Plate Glass Company's works at Ravenhead, in the adjacent township of Sutton, and of the copper works belonging to the proprietors of Parys Mine, in Anglesea, who brought their ore here to be smelted. Subsequently the Sankey Canal has been greatly improved and extended to Widness Dock, near Runcorn, at the opening of the estuary of the Mersey. Still more recently a line of railway has been formed from St. Helens to Garston, 3 or 4 miles above Liverpool, where a dock large enough to receive first-class vessels has been constructed, and where all the requisites for carrying on an extensive coal trade have been erected. The St. Helens Railway and Canal now form part of the undertaking of the London and North-Western Company, which has obtained permission to construct another dock at Garston. The town of St. Helens is the principal seat of the alkali manufacture, of the plate and bottle glass trade, and of the smelt-

ing of copper and other ores imported at Liverpool. Population of the town, 18,396.

Southport, a handsome new town on the estuary of the Ribble, 19 miles N. of Liverpool. It is much resorted to as a fashionable watering-place, and contains assembly-rooms, libraries, hotels, lodging houses, &c. The pier is about a mile in length, and the sands are excellent. A handsome park or pleasure ground was laid out in 1868, at a cost of 15,000*l.* The environs of the town are very picturesque and interesting. In 1851 the population was only 5391; in 1861, 11,303; and in 1869, 18,000.

Staleybridge. [STALEYBRIDGE.]

Stockport. [STOCKPORT.]

Todmorden, a market town, and a seat of extensive and flourishing manufactures, is 8 miles N.N.E. from Rochdale. It is a station on the Lancashire and Yorkshire, and the Manchester and Leeds Railway, and is also situate on the Rochdale Canal. It stands in the narrow mountain pass through which the river Calder flows down from the Lancashire hills into Yorkshire. The inhabitants are engaged in cotton and woollen manufactures, iron foundries, and in the working of quarries, and coal mines. There are two episcopal chapels, both of modern date, and also several dissenting places of worship. The population of the township, part of which is in the West Riding of Yorkshire, is 11,797.

Ulverstone is a parish and market town 16 miles N.W. of Lancaster. It stands on the north-western side of Morecambe Bay, with which it is connected by a short canal. There are extensive slate quarries in several parts of the parish, and numerous iron mines within a short distance. The town is pleasantly situated on a declivity sloping to the S., about a mile from the sands on the estuary of the Leven. It consists of four principal streets, spacious and clean. The church is a plain neat structure, and there are several places of worship for dissenters. Some manufactures exist of cottons and coarse linens, ropes, hats, and woollen yarn. The canal from the estuary of the Leven in Morecambe Bay enables vessels of 200 tons to come up and discharge their cargoes in a spacious basin close to the town, and regular steamboat communication is maintained with Liverpool. The population of the parish is 11,464; of the township, 6630.

Warrington, a parliamentary and municipal borough, is 18 miles E. from Liverpool, 21 miles by the London and North Western Railway; but a new line is in course of construction from the northern part of Warrington to Liverpool and Manchester, which will shorten both the distance and time of communication with both those places. Warrington is a place of great antiquity, and stands at a point where one of the principal Roman roads crossed the river Mersey. It is described in Domesday Book under the name of Walintune, and was then the chief place of a hundred of the same name that has since been united to the hundred of West Derby. It clusters on the right bank of the river among fertile market gardens, and consists of some modern streets, and several old and narrow ones, which contain many ancient timber houses. Warrington Bridge was for many ages the principal means of communication between Lancashire and Cheshire, and near to it the London and North Western Railway crosses the same

river. The town was made a parliamentary borough by the Reform Act of 1832. A municipal charter was granted in August, 1847, by which the town is divided into five wards, and governed by a mayor, nine aldermen, and twenty-seven councillors. The parliamentary and municipal limits are nearly coterminous; the number of inhabitants comprised within them being (1869) 29,940 and (1861) 26,431 respectively. The area of the borough is about 4000 acres, and comprises, besides the township of Warrington, portions of Latchford and Thelwall, both in Cheshire. Warrington is between Liverpool and Stockport, to which towns, and to Manchester, St. Helens, Newton, Wigan, Preston, Crewe, Chester, &c., lines of railway run. The first stage-coach from Lancashire to London began to run from Warrington in the year 1757, and made the journey in three days and three nights. In this town (which is the head of a deanery, and one of the polling-places for the county), petty sessions and county courts are held. During the civil war, in the time of Charles I., Warrington and the neighbourhood were the scene of many skirmishes between the royal and parliamentary armies. The principal buildings are, St. Elphin's parish church to the east of the town, of Saxon origin, a large, ancient, Decorated-English and cruciform building, of various dates, with three other churches and eight chapels, one of which, called the Wycliffe, is in the Gothic style; sessions house and bridewell, built in 1820; church and mechanics' institute; public museum and library, 1857; baths; savings' bank, and two other banks; diocesan training college for school mistresses; free grammar-school, founded 1526; clergy orphan daughters' school; blue-coat hospital and other schools; almshouses, dispensary, infirmary, lying-in society, and a union poor-house. A new public hall of handsome appearance was opened in 1862. A subscription library was established here in 1758. Besides these buildings there are—a town-hall, a market-house, two cloth halls, now disused, assembly rooms, and a theatre. The principal branches of industry in Warrington are cotton spinning, the manufacture of flint glass and glass bottles, soap, machinery, and millwork, and many branches of iron manufactures. There are steam flour mills, tanneries, malthouses, and several breweries—Warrington being famous for its ale. A cemetery has been laid out for public use at a cost of 11,804*l*. The Mersey is navigable up to Warrington at spring tides for very large vessels, and ships of 800 to 1000 tons have been built there and floated down to Liverpool. The Mersey and Irwell Navigation passes close to Warrington, as well as the Sankey Canal and the duke of Bridgewater's Canal. Warrington returns one member to the House of Commons; the number of registered electors in 1869 having been 1957.

Whalley is a very extensive parish, 30 miles in breadth and 15 in length, covering 105,249 acres. The town is of extreme antiquity, being mentioned by its present name in the Saxon Chronicle. It was afterwards the seat of a most powerful and wealthy monastery, the ruins of which still exist. Within the parish are included the borough of Clitheroe, three market towns, eighteen chapelrys, and thirty-two townships in the county of Lancaster, the small portions of land in the counties of Cheshire and York-

shire, in both of which the abbey of Whalley had considerable possessions. It is now intersected by the Liverpool and Leeds Canal, the East Lancashire and the Bolton and Clitheroe railways. Important manufactures of cotton, wool, and worsted are carried on in various parts of the district, which contains 167,456 inhabitants. Near Whalley is the Roman Catholic College of Stoneyhurst.

Wigan, a market town, and an ancient parliamentary and municipal borough, 18 miles N.N.W. from Manchester, stands on the Douglas, which is crossed by three bridges, and is navigable from Wigan to the estuary of the Ribble. It has a station on the London and North Western Railway, at the intersection of the Lancashire and Yorkshire line. The town is of considerable antiquity, and has enjoyed the right of returning members to Parliament from the time of the first Parliament called by Edward I. The old streets are irregularly built, but the new ones near the river have many good houses. From its situation on the richest part of the Lancashire coal-field, the wealth and population of the borough have increased rapidly with the development of its manufactures of cottons, cotton yarn, and linen. The extensive coal mines give employment to a large number of inhabitants; there are also iron works and foundries for machinery, tools, nails, brass wares, and spades. Cannel coal, chiefly used for the manufacture of gas, is found here in great abundance. The Leeds and Liverpool Canal passes through the town, and conveys the coal of Wigan to Liverpool and the whole intervening country. It is also carried to London in large quantities along the London and North Western Railway. The parish church is a very handsome structure, and the rectory is worth 2230*l*. per annum. Wigan has three other town churches, besides six in the outer parts of the parish, and ten chapels for Roman Catholics and dissenters. There is also a town-hall, built in 1720; cloth hall, in 1816; sessions hall, Moot or Manor Hill, corn exchange, two banks, gaol, barracks, mechanics' institute (1825), corn mills, about twenty cotton factories, a school of mines and industry, free grammar and blue-coat schools, dispensary, workhouse, &c. The main street is a mile and a half long. The municipal borough is divided into five wards, and is governed by a mayor, ten aldermen, and thirty councillors. Population of the borough and township, 37,658. In 1867 the population was estimated at 40,889. The parliamentary borough, which returns two members, is co-extensive with the municipal borough. The number of voters in 1869 was 4170. Petty sessions and county courts are held at Wigan, which is also a polling-place in the southern division of the county. This town supported the royalists in the civil war, and the old manor house, the seat of the Rev. Sir H. G. Gunning, Bart., lord of the manor and late rector, was occupied by Charles Edward in 1745. On the road leading northward from the town is a pillar in memory of Sir John Tyldesley, who was killed at the battle of Wigan Lane, when James earl of Derby was defeated there by Lilburne in 1659.

History and Antiquities.—In the earliest ages, that part of Great Britain which now forms the county of Lancaster, was inhabited by the Brigantes, the most powerful of all the British tribes, whose territory extended from the Mersey and the Humber to

the Tyne and the Solway. They were subdued by Agricola. The town of Ribodunum, now Ribchester, on the banks of the Ribble, is mentioned by Ptolemy, the geographer, as one of their settlements. After the Roman conquest of Britain, the whole territory of the Brigantes, which received the name of *Maxima Cæsariensis*, was covered with magnificent roads, whose course can still be traced in many parts of Lancashire. The most important Roman positions were Manchester, Ribchester, and Lancaster, all of which derive their names from the fact of their having been castra or camps of the Romans. Manchester was the principal, and several Roman roads have been traced, diverging from thence as from a common centre. After the retirement of the Romans from Britain, the Britons formed several states along the western side of the island, some of which long resisted the attacks of the Saxons and Angles, who had landed in the east, and who, after a conflict of 200 or 300 years, succeeded in conquering the more level parts of South Britain. The time at which the Saxons succeeded in establishing themselves in the present Lancashire is very uncertain. According to British accounts the favourite British hero Arthur, amongst many other victories, gained a great battle over the Saxon invaders on the banks of the river Douglas, which is in this county. Saxon chroniclers assert that Egfrid, the son of Oswy, king of the Saxon Northumbrians, conquered a part of this district between the years 670 and 685; but it is uncertain whether Lancashire, as a whole, was brought into entire subjection by the Saxons before the time of Edward the Elder, in 921, who subdued both the Danes and the Cumbrian Britons about that time. At the epoch of the Norman Conquest, the country now known as South Lancashire, was described as the land lying between the Ribble and the Mersey, and that part of the county that lies to the north of the Ribble was described as belonging to Yorkshire. The county of Lancaster is first mentioned by its present name in the reign of Henry II.

The earldom of Lancaster was created by Henry III. in favour of his younger son Edmund, and the duchy by Edward III. in favour of Henry, earl of Lancaster, the grandson of the above Edmund. Lancashire was made a county palatine for John of Gaunt, duke of Lancaster, son of Edward III., who had married Blanche Plantagenet, the daughter and heiress of the said Henry, duke of Lancaster. When Henry of Bolingbroke, the son of John of Gaunt, seized upon the crown of England, the duchy of Lancaster was still retained as a distinct possession, though inseparably connected with the crown of England, which is the case to the present day.

In the wars of York and Lancaster, the house of Stanley rose into great power and influence in Lancashire and Cheshire; and the closing battle of that long and sanguinary war, fought at Bosworth Field, was decided by the attack of the Lancashire men, headed by Thomas Lord Stanley, who was created Earl of Derby as a reward for his services to Henry VII.

In the great civil war, Lancashire, like all the northern counties, was the scene of numerous desperate conflicts; the greater part of the nobility and gentry, including the earl of Derby and Viscount Molyneux, taking the part of the king, whilst most of the towns adopted the part of the Parliament. The most

memorable events of this civil war in this part of England were—the siege of Manchester by the Royalists; the storming of Bolton and Liverpool, also by the Royalists; the defence of Lathom House by the heroic Charlotte, countess of Derby; the defeat of the duke of Hamilton's army by Oliver Cromwell, near Preston; and the defeat of the earl of Derby by Colonel Lilburne, in Wigan Lane.

The most celebrated castles are those of Lancaster and Hornby, both of which are in good preservation. The castles of Thurland and Greenhalgh, Houghton Tower, and the ancient castle of the Stanleys, known as Lathom House, are either in ruins or entirely destroyed; the stronghold of the De Lacy family at Clitheroe is a picturesque relic of antiquity. The castle of Liverpool was destroyed by order of the king in the reign of Charles II., but the foundations can still be traced. Numerous fine manor houses exist in different parts of the county, the most beautiful of which is Speke Hall, near Liverpool.

The monastic ruins are of great interest. Furness Abbey, in the Vale of Deadly Nightshade, near Dalton, in Furness, is one of the finest monastic memorials in England. It is situated in a deep, narrow glen, but surrounded by a fertile, well-cultivated country. Its remains are magnificent; and from the seclusion and picturesque beauty of the neighbouring scenery, produce a vivid impression on the mind of the spectator. The abbey was founded by King Stephen, when earl of Morton and Boulogne. It was magnificently endowed by him and his successors, and was for many ages in the first rank amongst the monastic institutions of England. Its ruins, which are of the Norman and early English character, include portions of the church, chapter house, the cloisters, the school-house, and other buildings. Whalley Abbey, founded by the De Lacys, earls of Lincoln and constables of Chester, is also a noble pile, beautifully situated on the river Calder, near the point where it joins the Ribble. Remains of monastic buildings of smaller importance are found in other parts of the county.

LANCASTER, DUCHY OF. Lancaster was made a county palatine by Edward III., and conferred on Henry, duke of Lancaster, and at his death, on John of Gaunt and his heirs for ever. Henry VI. was, therefore, hereditarily Duke and Count Palatine, and on his attainder, soon after Edward IV.'s accession, the duchy and county were forfeited to the Crown, and confirmed on Edward IV.; and afterwards, in like manner, on Henry VII. and his heirs for ever. The Queen is now duchess and countess palatine of Lancaster. The revenues of the duchy are independent of those granted by the civil list [CIVIL LIST], and the net proceeds are paid over to the privy purse, uncontrolled by Parliament, except that an account must be annually rendered.

The duties of the chancellor of the duchy and county palatine are few and unimportant, as the administration of justice is now assimilated to that of the rest of England. The office is, however, usually conferred on an eminent statesman, frequently a member of the cabinet, whose emoluments are about 2000*l.* per annum. By 17 & 18 Vict. c. 12, the chancellor of the duchy, with the two lords justices of the Court of Appeal form the Palatinate Court of Appeal.

LANCASTER, SIR JAMES, a skilful seaman, who conducted the first voyage undertaken by the East India Company in 1600-3, and established commercial relations with the princes of Acheen in Sumatra, and Bantam in Java. He was a firm believer in a north-west passage; and Lancaster's Sound, a deep inlet in Baffin's Bay, 74° N. lat., was named after him. He died in 1620.

LANCE (Latin, *lancea*, Greek, *logche*), the weapon used by the 5th, 9th, 12th, 16th, and 17th regiments of Dragoons, on that account specially termed *the Lancers*. [CAVALRY.] The lance is a long rod of tough ash, with a steel point, and usually a coloured flag near it. The ancient *lancea* was a general term for javelins or weapons cast by the hand. The lance was held in high esteem both among the Macedonian phalanx and the Roman infantry, and even at the present day is considered a useful weapon for cavalry, though the great improvements effected in fire-arms have diminished its efficiency. In the Middle Ages, the terms *lance* and *man-at-arms* were synonymous.

LANCELET. [BRANCHIOSTOMA.]

LANCEOLA, a genus of Crustaceans established by Mr. Say on a species, *Lanceola pelagica*, two females of which only he appears to have seen taken on the coast of America, in the Gulf Stream. M. Desmarest is of opinion that the genus belongs to the order *Amphipoda*.

LANCERS. [CAVALRY, LANCE.]

LANCET ARCH, in architecture, an arch, the vertical point of which is like the head of a lancet. It is usually applied to long narrow windows, and is the oldest form of arch known in the East. The Gothic style passed from the East, through Italy and France, to England; and the lancet arch is its earliest feature. Bishop de Lucy first introduced the lancet arch, supported by clusters of slender columns, with capitals of foliage, into the Cathedral of Winchester, at the commencement of the thirteenth century. It is a prominent feature of what is called the early English style of ecclesiastical architecture.

LAND, in English law, in its most restricted signification is confined to arable ground. In this sense the term is construed in original writs, and used in all correct and formal pleadings.

By the Statute of Wills, 1 Vict. c. 26, s. 26, a devise of the land of the testator generally, or of the land of the testator in any place or in the occupation of any person mentioned in the will, is to be construed to include customary, copyhold, and leasehold estates, to which the description will extend, as well as freehold estates, unless a contrary intention appear by the will. In its more wide legal signification, land includes meadow, pasture, woods, moors, waters, &c.; but in this wider sense the word generally used is lands: the term land or lands is taken in this larger sense in conveyances and contracts.

A conveyance of land includes all that is attached to the land and all that is under it. Ownership of land and all estates in land, except chattel interests, are included in the term *real property*, in contradistinction to *personal property*, which consists in money, goods, and other movables. Land held for a number of years or other determinate time is a chattel interest, but it is distinguished from other chattels by the name of *Chattels Real*. [CHATTELS.]

Land Derelict, or left dry by the sudden receding of the sea, or of the water of a navigable river, belongs to the king by his prerogative. Land formed by alluvion, that is, by gradual imperceptible receding of any water, or by a gradual deposit on the shore, accrues to the owner of the adjoining land. The rules of English law as to alluvion, as stated in Bracton (folio 9), are chiefly copied from the 'Digest' (41 tit. i. s. 7).

In Scotch law the terms *heritable* and *moveable* are used to express the different classes of property known in English law as *real* and *personal*, these latter phrases being employed to denote certain distinctions in the nature of the right which a person possesses in a subject either heritable or moveable. Generally all rights in or pertaining to land are heritable. Things attached by art or by nature to land, such as machinery and trees, are heritable. Leases, though in their nature merely *personal* contracts, have, by the Act 1449, c. 18, been rendered heritable subjects.

LANDAMMAN, the chief governor or president of the diet of the Swiss republic. In ten of the cantons the head magistrate also bears the same title.

LANDAU, a town in the Bavarian circle of the Rhine, 18 miles N.W. of Carlsruhe, important on account of its fortifications, which were constructed by Vauban, is situated in a beautiful valley on the river Queich, and on a canal, by which provisions, materials for building, &c., are conveyed to it by water. The barracks and casemates are bomb-proof. The town is very regularly built within, has two gates, a large parade, a gymnasium, and manufactures of tobacco, calico, woollens, linen, hats, and fire-arms; copper and iron foundries, &c. The population amounted to 12,244 in 1861. Landau is one of the fortresses of the German Confederation, and is garrisoned by Bavarian troops. The town was held by the French from 1680 to 1815.

LANDAU, the name given to a carriage which may be opened and closed at the top. This species of vehicle was first made at Landau in Germany; hence the name.

LAND-CRAB. [GECARCINUS.]

LANDED ESTATES COURT. [IRELAND.]

LANDED MEN, in Scotch law, where the panel in a criminal trial is a landed proprietor, he is entitled to be tried by a jury consisting for the most part of his peers.

LANDER. [NIGER.]

LANDERNAU. [FINIST'ERE.]

LANDES, a department in the south-west of France, takes its name from the French word *landes*, by which the vast sandy plains that extend between the Garonne and the Adour from the meridian of Greenwich to the Bay of Biscay are designated. It formed part of the old province of Gascogne, and is bounded N. by Gironde, E. by Garonne and Gers, S. by Basses-Pyrénées, and W. by the Bay of Biscay. It extends from $43^{\circ} 30'$ to $44^{\circ} 28'$ N. lat., $0^{\circ} 10'$ E. to $1^{\circ} 31'$ W. long. Its greatest length from E. to W. is 72 miles, and from N. to S. 66 miles. The area is 3599 square miles. The population, by the census of 1866 was 306,693. The department is the most thinly populated and also the most sterile in France.

Aspect, Soil, &c.—The lower slopes of the Pyrenees

enter the south and south-east of the department, furrowed by many brawling rivers, and subsiding into rich plains that extend along the left bank of the Midouze and the Adour, which rivers form the general southern boundary of the landes. To the northward of these rivers, the surface of the ground is covered with a loose ashen-gray sand, overgrown here and there with heath and furze, or covered with pine woods. Numerous flocks of wretched half-starved sheep wander over this desert waste, tended by shepherds who walk on high stilts to enable them to pass dry-footed over the marshes that occur in all directions. Clothed in sheep-skins, perched on his lofty stilts, and seated on a high staff with a flat broad end, the shepherd of the landes watching his sheep, and knitting woollen stockings, his constant occupation, presents to the stranger an extraordinary appearance. Not only the shepherds, but the charcoal burners, and almost all the scanty population of the landes, are accustomed to the use of stilts, on which they walk with astonishing rapidity. The human habitations are of the rudest description, little superior to the huts and wigwams of savage tribes, but the inhabitants are good-natured and hospitable. Maize and barley are grown in favourable situations in this district; but the most important produce of the landes are the pine forests which cover nearly one-fourth of the surface, and which, besides the value of the timber, and the great quantity of rosin the trees are made to yield by tapping, are found to present a most effectual barrier to the sand hills or *dunes* along the west coast, that formerly rolled into the interior under the influence of the western winds, and overwhelmed the villages and crops exposed to their course. The surface of the landes is rather elevated, as is proved by the rapidity of the rivers-streams which flow from them towards the south, west, and north-west: the largest of these is the Leyre, which flows north-west into the Bay of Arcachon. The chief rivers of the department are the ADLOUR, which receives numerous feeders from the Pyrenees on the left bank, and its principal tributary from the right bank, the Midouze. [GERS.]

Along the sea-coast of the department, which extends N. and S. about 70 miles, a marked feature of the country are the sand-hills, which have a width from E. to W. of 5 miles; their height ranges from 120 to 170 feet; they slope towards the sea at an angle of 25°, towards the land at an angle of 50°. The form of these masses of sand is continually varying; sometimes they are arranged in regular chains, at others they present a level surface; and not unfrequently they assume the form of isolated heaps, the openings between them being called *Lettes*. The rate of advance of these moving sands is said to be 65 feet yearly. To landward of them there are in some places rich pasture lands. There are several shallow inlets and some isolated lagoons along the coast; and all through the landes there are numerous marshes, the exhalations from which render the climate foggy in winter, and always more or less unhealthy. The marshes which formerly lined the banks of the Adour have been almost entirely converted into productive land.

Products.—The department contains 2,261,439 acres. The products, most of which are raised in the territory of *Chalosse*, as the country south of the

Adour is called, are wheat, maize, millet, hemp, flax, madder, saffron, &c. About 10,000,000 gallons of wine are produced annually, of which about a third goes to supply the home consumption; the rest is exported, or distilled and sold as Armagnac brandy. Almonds, plums, and fruits of all kinds, are abundant and excellent. Cattle are of inferior breed, ill-fed, and give milk of the poorest quality; the horses are small; sheep are numerous, but their wool is the worst possible; goats, pigs, poultry, and bees are numerous; game and fish are plentiful. Besides the pine, which grows most luxuriantly in the landes, the forest timber consists of oak, cork, chestnut, and beech.

Mines of iron and bitumen are worked; mica, coal, marble, granite, lithographic stone, chalk, ochre, potter's clay of superior quality, crucible earth, &c., are found. Peat fuel is dug. Mineral springs are numerous.

The industrial produce is composed of coarse woollens, pottery, liqueurs, bar iron and ironware, rosin, pitch, tar, glass, paper, leather, brandy, beer, oil, &c. There is also a considerable trade in timber, charcoal, deals, linseed oil, fruits, wool, pork, &c.

Divisions, Chief Towns, &c.—The department is divided into three arrondissements, which, with their subdivisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop.in1863.
Mont-de-Marsan, . . .	12	118	107,428

Of the arrondissement of Mont-de-Marsan and of the whole department the capital is *Mont-de-Marsan*, which stands in 45° 53' N. lat., 0° 30' W. long., 65 miles S. from Bordeaux, and nearly the same distance N.E. from Bayonne. The town, though small, and with a population of only 5574, presents a thriving appearance, and its situation at the junction of the Midou and the Douze, which form the Midouze, a navigable feeder of the Adour, give it considerable advantages in the way of commerce. The streets are wide and well built, and there are several fine avenues of ancient oaks leading into the town. The principal structures are the prefect's residence, the court-house, prison, the hospital, and barracks. The town is the seat of a tribunal of first instance, and has a college, public library of 12,000 volumes, a theatre, and several warm mineral baths. Cloth, blankets, sail-cloth, and leather are the principal manufactures. Mont-de-Marsan has communication with the Garonne by the Canal des Landes, which at Lavardac joins the Baise, a navigable feeder of the Garonne. The most important commerce of the town consists in the wool and agricultural produce of the surrounding country, and in the transport of the wines and brandies of Armagnac by the Midouze and the Adour for shipment at Bayonne. *Pissos*, near the Leyre, has potteries, iron-works, and 1951 inhabitants. *Roquefort*, at the junction of the Estampon with the Douze, has a population of 1745, who are engaged in the manufacture of earthenwares.

Sabres, a town of 2525 inhabitants, stands on the Leyre in the midst of barren wastes and marshes, and has a very handsome church said to have been built by the Templars. *Sore*, in a good wine district in the middle of the landes N. of Mont-de-Marsan, has potteries, glass-works, and 2006 inhabitants, who also raise vast quantities of turf for fuel.

In the arrondissement of St.-Sever, the chief town, *St.-Sever*, is situated in an extremely fertile country on the left bank of the Adour, 10 miles S. from Mont-de-Marsan, and has a tribunal of first instance, a college, and 4818 inhabitants, who manufacture fine pottery, linseed oil, and leather, and trade in corn, wine, brandy, mineral waters, marble, cut stone, plaster, &c. The town is well built, and contains some handsome buildings; among which must be named the court-house, the hospital, barracks, prison, and a magnificent church, which formerly made part of the Abbey of St.-Sever. *Airé* (*Vicus Julius*), an episcopal and ancient city, stands on the slope of a hill on the left bank of the Adour, which is here crossed by a handsome stone bridge, 17 miles E. from St.-Sever, and contains an ecclesiastical college, a very ancient church, and 5144 inhabitants. The town, which is neat and well built, has manufactures of hats and leather. It is a bishop's see, and was anciently important as the capital of the Visigoths. *Amou*, a pretty little town of 1834 inhabitants, is situated in a very fertile corn and wine country near the junction of the Luy-de-France with the Luy-de-Béarn, and has potteries, brandy distilleries, tile works, and numerous flour, oil, and bark mills. *Hagetmau*, a town of 3029 inhabitants, stands in a district abounding with game, on the Louts, 7 miles S. by W. from St.-Sever, and has manufactures of household linen, pottery, leather, and several oil mills. It has also a good trade in excellent wine, corn, maize, flax, chestnuts, hides, and cattle. Great quantities of oak staves and hoops are despatched to Bordeaux. *Mugron*, situated at the foot of a hill on the left bank of the Adour, has 2150 inhabitants, who trade in brandy, wine, rosin, and silk. *Tartas*, W. by N. from St.-Sever, is a well built ancient town prettily situated on the Midouze, and has 3084 inhabitants, who manufacture linseed oil, vinegar, and leather, and trade largely in corn, wine, brandy, saffron (of which a great deal is grown in the neighbourhood), fruits, game, hams, timber, planks, rosin, &c.

In the arrondissement of Dax, the chief town, *Dax*, situated in a fertile plain on the left bank of the Adour, over which passes a bridge to the suburb of Sablar, is a well built town, surrounded by ramparts and fosses of Roman construction, 30 miles S.W. from Mont-de-Marsan, and has 9856 inhabitants. The town, which is entered by three gates, is defended by a strong castle. The chief buildings are the chamber of commerce, the former episcopal palace, now occupied by the sub-prefect and the mayor, the court-house, the cathedral, and the gaol. Dax has a tribunal of first instance, a college, and a considerable commerce in liqueurs, wine, brandy, corn, hams, onions, timber, deals, rosin, &c. There are manufactures of earthenware, linen thread, linseed oil, vinegar, and leather. It has been famous from the most ancient times for its hot mineral springs (temp. 162° Fahr.), whence its ancient name of *Aquæ*, of which Dax (*d'Acqs*) is a corruption. *Aquæ* or *Aque*

Tarbellicæ was the capital of the Tarbelli, a people of Aquitania. *St.-Esprit*, a seaport in the south-western extremity of the department, and on the right bank of the Adour, here crossed by a long wooden bridge which joins the town to Bayonne, is a large busy town, by far the greater part of whom are descendants of Jewish refugees from Spain. The citadel of St.-Esprit, constructed by Vauban, commands the town of Bayonne, and the approaches to it by land and sea. [BAYONNE.] The Jews have three synagogues here, in one of which a rabbi preaches every Saturday in Spanish. *Peyrehorade*, on the right bank of the Gave-de-Pau, which here becomes navigable, and a few miles lower down enters the Adour, has 2516 inhabitants. It has a fine old castle flanked with towers. Large stores of ship-timber from the forests of the Pyrenees are kept here; there are also important quarries in the neighbourhood. *Soustons*, on the eastern shore of the lagoon of Soustons, 17 miles W. from Dax, has a population of 3285.

The department forms the see of the bishop of Aire, is comprised in the jurisdiction of the Cour Imperiale of Pau, and of the University Academy of Bordeaux, and belongs to the thirteenth military division, of which Bayonne is head-quarters. It returns 23 members to the Chamber of Deputies.

(*Dictionnaire de la France; Annuaire pour l'An* 1866; Malte Brun, *Géographie Universelle*.)

LANDGRAVE (German, *landgraf*), a title assumed by some German counts in the twelfth century as counts of the whole country, and now borne by several German princes.

LANDING-WAITER, formerly an officer of the customs, whose duties consisted in taking an accurate account of the number, weight, measure, or quality of the various descriptions of merchandise landed from foreign countries or colonial possessions. Landing-waiters likewise attended to the shipment of goods. The term landing-waiter was abolished in 1860, and the persons now employed in the above duties are called examining officers.

LANDIVISIAU. [FINISTERE.]

LANDLORD AND TENANT. [TENANT AND LANDLORD.]

LANDMARK, any mark to designate the boundary of land, or any elevated object that serves as a guide to navigation. Among the early Asiatics, Egyptians, and Jews, landmarks were in use for distinguishing the common divisions of lands; and the emphatic language used by Moses, 'Cursed be he that removeth his neighbour's landmark,' is sufficient to show the importance in which these marks were held. Among the Romans they sometimes used boundaries of stones, where figures of the god Terminus were erected. In the Middle Age crosses were usually placed to mark the boundaries of land, and sometimes to indicate the property of the soil.

LONDON, LETITIA ELIZABETH (Mrs. Maclean), an English poetess, known by the signature L.E.L., was born in Hans Place, Chelsea, on the 14th of August, 1802. She began very early to write verses, and Mr. Jordan, the editor of the *Literary Gazette*, published some of her effusions in his journal. In her eighteenth year, Miss Landon gave to the world a volume of poetry, which included 'The Fate of Adelaide,' a romantic tale replete with

poetic talent. Immediately afterwards she began, in the *Literary Gazette*, a series of 'Poetical Sketches,' subscribed by her initials only. In 1824 appeared 'The Improvisatrice,' which met with a triumphant reception. 'The Troubadour,' 'The Golden Violet,' 'The Venetian Bracelet,' followed in due order, and maintained the writer's popularity. She also published three novels—'Ethel Churchill,' 'Francisca Carrara,' and 'Romance and Reality.' From 1831 to 1837 she edited 'Fisher's Scrap Book' with much credit. Her poems are characterized by romantic imagery and passionate sentiment, and tinged with the Byronism of the day. In June, 1838, Miss Landon was married to George Maclean, Esq., governor of Cape Coast Castle, where, having lived happily with her husband for twelve months, she died on the 15th of October, 1839, from an overdose of prussic acid, a medicament she was accustomed to take for the relief of neuralgic pains. In 1841, her friend, Mr. Laman Blanchard, published her 'Life and Literary Remains' in two volumes.

LANDOR, WALTER SAVAGE, a versatile and gifted author, son of Walter Landor and Elizabeth Savage, was born on the 30th of January, 1775, at Ipsley Court, Warwickshire. He was educated at Rugby, and at Trinity College, Oxford. In 1795 he published a small volume of poems. His tragedy of 'Count Julian' led to a life-long friendship with Southey. In 1808 he raised a body of troops at his own expense, joined the Spanish patriots under Blake, and received a colonel's commission in their army. But in 1814, on the restoration of Ferdinand, he resigned his commission, declaring that, 'though willing to aid the Spanish people in the assertion of their liberties against the antagonist of Europe, he would have nothing to do with a perjurer and a traitor.' In 1811 he had married Miss Julia Thuillier, of Bath, and he now resided for some time at Tours, removing to Florence in 1815, where he remained for more than thirty years, occupying himself with the education of his children and literature. In 1820 he published 'Idyllia Heroica' in Latin, and in 1824–29, 'Imaginary Conversations of Literary Men and Statesmen,' his greatest work, exhibiting a wide range of minute literary and biographical knowledge, ancient and modern, and a vigorous, robust, and original style. In 1836 he published 'Letters of a Conservative,' 'A Satire on Satirists,' and 'Pericles and Aspasia.' In 1837 appeared the 'Pentameron,' in which Boccaccio and Petrarca discourse familiarly on things in general and Dante in particular. In 1846 Mr. Landor came to England, and occasionally contributed articles to the *Examiner* and other journals. In 1847 he wrote 'The Hellenics,' in 1848, 'Imaginary Conversations on the Affairs and Prospects of Italy,' in 1851, 'Popery, British and Foreign,' in 1853, 'Last Fruit of an Old Tree,' in 1854, 'Letters of an American,' and in 1858, 'Dry Sticks Faggoted,' a collection of all kinds of poems, from the idyllic to the satirical. The Italian revolution enlisted Mr. Landor's keenest sympathies, and in his ardour he went the length of advocating and instigating something very like tyrannicide. His chief virtue was a warm love of his kind, and a consistency of principle which made it always probable that, whatever side might be vic-

torious, Landor's would be just. He lived to fight in many fierce battles, and to lose many. The ardour of his nature, which was essentially and sometimes outrageously combative, led him into personal and literary warfare, and probably into a contest at the close of his life which was ridiculous and deplorable. But on the side of his taste, which was exquisitely cultured, and his feelings, which were kindly and gentle generally, he was what Emerson described him in 1833. 'I had expected an Achillean wrath, an untameable petulance; instead of that I found courtesy, and the most patient and gentle of hosts. He has a wonderful brain, despotic, inexhaustible; meant for a soldier, but converted to letters, yet with an English appetite remaining for action and heroes. He died at Florence, September 16, 1864.

LANDRECIES. [NORD.]

LANDSBERG. [BRANDENBERG.]

LANDSEER, JOHN, Associate Engraver of the Royal Academy, was born at Lincoln in 1761. His early instructor in the art from which he has obtained so much celebrity, was Mr. W. Byrne, the well-known landscape engraver. In 1795 the name of Landseer first made its appearance on the title-page of twenty views in the south of Scotland, from drawings made by James Moore. In 1806 he delivered a series of lectures on the art of engraving, which he defined as 'a species of sculpture, performed by incision,' and proceeded to illustrate the subject with much ingenuity and learning. In the same year he was elected an Associate Engraver of the Royal Academy; and afterwards entered into some lengthened controversies with the academy on the question of admitting engravers to the rank and title of royal academicians. In 1823 he published a work, under the title of 'Sabaean Researches,' comprising a series of lectures delivered to the Royal Institution on the engraved hieroglyphics of Chaldaea, Egypt, and Canaan. In 1834 Mr. Landseer presented to the world a lively and learned criticism 'On fifty of the earliest Pictures in the National Gallery.' It affords a variety of information, communicated in a very amusing form, and in a way which none but an artist, as well as a scholar, could have imparted. He died in 1852. Two of his sons, Charles and Sir Edwin Landseer, inherited their father's artistic genius, and became members of the Royal Academy. The latter distinguished artist, who is famous for his pictures of animal life, is now engaged in sculpturing the lions intended to adorn the base of Nelson's Column, in Trafalgar Square, London.

LAND'S END, the ancient *Bolerium*, is a celebrated headland forming the western extremity both of Cornwall and of England, and boldly projecting its bluff stern front into the Atlantic. The terminal rocks rise in a perpendicular precipice of 60 feet of granite above a sea which is never calm. About a mile to the westward lies the dangerous Longships Rock, which is 60 feet in height, and covered by a lighthouse 50 feet from base to summit. Lat., 50° 4' 44" N.; long., 5° 44' 44" W. Close by this famous promontory is Cape Cornwall, with Whitesand Bay below it, memorable as the landing-place of King Stephen on his coming to England, of King John on his return from Ireland, and of Perkin Warbeck on his fruitless enterprise against the throne of Henry VII. (Wilkie Collins, *Rambles Beyond*

Railways; Rev. J. A. Johns, *A Week at the Land's End*; Black's *Guide to Dorset, Devon, and Cornwall*; Murray, *Handbook to Devon and Cornwall*, &c.)

LANDSHUT, a pretty town in Bavaria, with 12,135 inhabitants in 1861, is situated on the Isar, which is here crossed by two bridges. The principal portion of the town consists of two long, broad, and straight streets, connected by a number of narrower ones. The houses are well built of brick, and many of them have gardens. The most remarkable buildings are the palace, the house of the provincial assembly, a hospital, and two parish churches, of which St. Martin's is celebrated for its beautiful steeple, 450 feet in height, and commanding a magnificent view over almost the whole plain of Bavaria. On a mountain near the town is the ancient castle of Trausnitz, which was formerly a strong fortress, and the residence of the dukes of Bavaria. In the year 1800 the University of Ingolstadt was transferred to Landshut; but in 1826 it was removed to Munich. There are, however, still a theological college, a gymnasium, a lyceum, and a school of surgery. There are extensive breweries and distilleries in the town, and manufactures of woollen cloths, hosiery, tobacco, paper, cards, and leather, with a trade in corn, cattle, and wool. Landshut is inclosed by old fortifications, and consists of an old and a new town, with a suburb on an island in the Isar.

LANDSLIPS. This term is applied to portions of land which become detached and slide down to a lower level. The phenomenon is produced by various causes. Water is the principal agent, as it percolates through the cracks and fissures of the earth, and gradually widens them until a portion falls away. It also sometimes happens that when the strata are very much inclined, and rest on a bed capable of absorbing moisture, the latter becomes so slippery that the land glides bodily over its foundation.

LAND-TAX. [TAXATION.]

LANDWEHR (Ger. *land*, and *wehr* 'defence'), the militia of Austria and Prussia. In Austria they are a kind of reserve to each regiment of the line, and drilled once a year under the same colonel. In Prussia the military consists of the youth of the kingdom, from twenty to twenty-five years of age; every subject being obliged to enter into the military service at that age. After two or three years' service the soldier can proceed to his own home, but is liable to be called upon to join his regiment at every emergency. At the expiration of five years from the date of enlistment, the men are drafted into the first class or levy of the landwehr, remaining in it until their thirty-second year. In time of war they are liable to be called upon to serve with the regiment of the line of a corresponding number; in fact they form the reserve of that regiment, whence reinforcements are drawn. From their thirty-second to their thirty-ninth year the men belong to the second levy, and are only called out occasionally in time of peace; but in war they garrison fortresses.

LANE END. [STAFFORDSHIRE.]

LANFRANC, archbishop of Canterbury, was born at Pavia in 1005. He spent some years in the study of rhetoric and civil law at Bologna, and he afterwards became prior of the abbey of Bec. William, duke of Normandy, made him one of his counsellors,

employed him in an important embassy to the pope, appointed him in 1062 abbot of his newly erected monastery of St. Stephen at Caen, and eventually procured his election, 15th August, 1070, to the see of Canterbury, the cathedral of which Lanfranc rebuilt. He died May 28, 1089.

His writings consist of commentaries on St. Paul's Epistles, sermons, letters, and his treatise on the Eucharist against Berenger. His works were collected and edited by Lucas d'Achery, at Paris, folio, 1648.

LANGDALE, RIGHT HON. H. BICKERSTETH, LORD, Master of the Rolls, was born at Kirkby Lonsdale, Westmoreland, in 1783. His father was a country surgeon and apothecary. He was educated at the free grammar-school of his native place, and served his apprenticeship to his father. He afterwards entered himself of Caius College, Cambridge, where, in 1808, he graduated as senior wrangler. Having entered himself of the Inner Temple, he was called to the bar in 1811. In 1827 he became King's Counsel, and a Benchler of the Inner Temple, and filled the office of treasurer in 1836. Though of liberal politics, his talents were held in the highest estimation by all parties. In 1836 he was appointed to succeed Lord Cottenham as Master of the Rolls, and at the same time called to the House of Peers. He had thus risen, by an unusual exception, to one of the most honourable and important posts in his profession without having entered the House of Commons, or mingled in party politics. On the resignation of Lord Cottenham the great seal was more than once tendered to him; but which he did not hesitate to decline. He died in the year 1851.

LANGEAIS. [INDRE-ET-LOIRE.]

LANGHOLM. [DUMFRIESSHIRE.]

LANGON. [GIRONDE.]

LANGPORT. [SOMERSET.]

LANGRES, a town in the French department of Haute-Marne, which takes its name from the *Lin-gones*, an ancient Celtic tribe whose capital it was, is situated in 47° 51' 53" N. lat., 5° 19' 55" E. long., at a distance of 158 miles S.E. from Paris, and had, in 1861, 10,132 inhabitants. The town, built on the watershed between the Mediterranean and the Atlantic, near the sources of the Marne, the Meuse, the Amana, and the Vingeanne, occupies a higher site than any other town in France, except Briançon, being 1460 feet high. It is surrounded by old walls, and is pretty well built, with wide streets, and is ornamented with fountains and promenades. The most remarkable structures are—the cathedral, part of which dates from the year 380, the town-hall, and a Roman triumphal arch, which makes part of the town wall. The greatest ornament of the town is the promenade called Blanche-Fontaine, which is formed of an avenue of magnificent limes, nearly a mile in length, and terminates in a majestic vaulted arcade, from the top of which a colossal frog in bronze continually spouts a mass of limpid water that feeds several basins and jets. The public library of 7000 volumes is in the town-hall: there is a museum in the old church of St.-Didier. The chief manufacture of Langres is cutlery; there is also a considerable trade in corn, flour, wine, flax, hemp, wool, &c. The town, which gives title to a bishop,

is the seat of tribunals of first instance and of commerce; it has two ecclesiastical schools, a college, a school of geometry, and three hospitals. A great number of Roman antiquities have been found near Langres.

LANGTON, STEPHEN, was a native of England, and was born in the earlier half of the twelfth century. After finishing his studies at the University of Paris, he rose to the office of its chancellor. Langton was consecrated archbishop of Canterbury by Innocent III. at Viterbo, June 17, 1207. It was he who, at the meeting of the heads of the revolt at London, August 25, 1213, suggested the demand for a renewal of the charter of Henry I. He continued to preside over the church till his death, July 9, 1228.

LANGUAGE. The origin of language, like that of man himself, is unknown, beyond the brief statement in the book of Genesis. That man has the faculty of speech is only another mode of saying that by his nature he is qualified to produce all the sounds which compose spoken language. Whether man gradually formed language, stimulated by his instincts for social life, and guided by his intellectual powers; or whether language, and not the bare faculty of speech, was conferred on him by the same power which called him into being, are questions that cannot be positively answered. But the former theory is the one most generally accepted by those best qualified to speak on the subject, as they consider it is very clearly demonstrated that language is a spontaneous product of human nature—a necessary result of man's physical and mental constitution (including his social instincts), as natural to him as to walk, eat, or sleep, and as independent of his will as his stature or the colour of his hair.

A definition, or rather a description, of what language is may be required at the outset of these remarks: that which we shall give does not aim at such a degree of accuracy as to be above criticism; it is merely such a description as will show what it is that we are speaking about.

Language consists of vocal sounds [LARYNX]. Any sounds, then, are a component part of language which produce in the hearer the counterpart of that mental state of which these sounds are the material and sensible signs. But language presents great varieties; and though all languages have many sounds in common, which are universally significant and intelligible, the greatest part of the sounds composing any given language are only intelligible to those who from long experience have become familiar with them. But this fact does not affect the definition of language. If any two human beings can by vocal sounds mutually convey to each other their desires, thoughts, and conceptions, this possession of a common power and capacity constitutes the possession of a common language. When this power and capacity are common to a considerable number of persons living in a community, the exercise of them constitutes and makes a language.

A language, then, must be viewed as the totality of the vocal sounds by which the members of any given society communicate to one another their ideas. As action or motion of the body and its parts, and the application of the bodily powers to various purposes and ends, are the signs and expression of the

sensations and of the will—the result, as it were, of the moving power within—so language, which is itself in its material character nothing more than a corporeal act, is another mode of expressing the same things. But language is also the expression of our intellectual and judging faculties; and its form is therefore necessarily subordinate to the laws of the human mind.

Thus language can do more than other corporeal acts: they can only express desire, will, purpose, design, but they cannot express many of those things which only exist as conceptions of the mind, or are only modes and forms in which the mind, according to its laws, views things and the relations of things. Language, therefore, in addition to its power of expressing what can be expressed by other corporeal signs, has a peculiar power of conveying from one person to another notions as conceived by the mind, which have no actual existence, or can only be mentally conceived to exist. The degree in which language is capable of doing this depends on the mental cultivation of the people who use it; for without such cultivation language is not wanted for the expression of many notions, and unless preceded by or accompanied by such cultivation, such part of language cannot exist. The language of many nations may be so poor as to convey very little more from one person to another than can be conveyed by other corporeal signs; or a very few sounds and combinations of sounds, aided by the other natural signs, may be sufficient for all the purposes of social existence. But even in the poorest languages many general terms are required to express the meaning of a speaker when the objects referred to are not present, and there is no language which does not contain a considerable number of abstract terms, indicating not only things and qualities which are the objects of a sensuous intuition, but also those which are the objects of a non-sensuous intuition. Every language also must, to some extent, express the mode in which the mind contemplates the relations of things.

The matter, then, of which language consists is vocal sounds expressive of ideas: its form is the relation of those sounds to one another, which is expressed (within certain limits) chiefly by their arrangement. In order that the several sounds may convey the same meaning, the same sounds must be used for the same purposes—that is, the meaning of any single sound must, generally speaking, at least for any given epoch, be fixed. The arrangement of the vocal sounds must also be tolerably well fixed, in order that the same set of sounds may convey the same meaning.

Even in many of the simplest sentences, consisting only of two or three words, every or nearly every language has a definite order for expressing one meaning by such words, and another order for them when they are to express a different meaning. Sometimes the difference of meaning may be conveyed by the greater or less stress laid on a particular sound, or by some change in the intonation of voice, which is in effect a change in the sounds, and therefore all that is necessary to mark a difference. This power which spoken language possesses gives it one advantage over written language, in the use of which we are sometimes obliged to use supplementary signs or marks to express what the voice can more surely effect.

If we analyze the vocal sounds of a language, we can separate them into two chief classes: sounds which of themselves convey a notion, and may therefore be called *notional*, such as 'man,' 'horse,' 'virtue,' 'vice,' 'come,' 'walk;' and sounds which only serve to connect notional words and to indicate the relation between and among them, and may therefore be called *relational*, such as 'from,' 'to,' 'who,' 'which.' Many of these relational words, perhaps all of them, may once have been notional; and their precise meaning and value, in the case of languages no longer spoken, can only be determined by tracing them to their origin, or to such source as we are compelled by want of other evidence to consider as their origin; but this is no objection to our statement of what a language consists as an actual phenomenon. The actual meaning of all the words which compose a language must be determined by their actual use. Their former meaning and their history must be determined by a reference to the language as formerly used, the evidence of which use is the written language.

The various modes of recording language, or the representations or marks by the aid of which sounds can be at any time reproduced equivalent in meaning to those by which the writer would have orally expressed what he has expressed, by signs or marks on paper, or any other durable substance, make what we call Writing. It will be sufficient at present to observe, that the mode in which the sounds of any given language are represented must not be considered as necessarily indicating anything peculiar in the language itself.

It is difficult to conceive that any words at first were more than monosyllabic sounds; at least, so far back as we can trace any known language, such seems to be the only result. By this it is not meant to say that a syllable is one simple sound, but that the monosyllabic sounds here meant are such as in their integrity expressed one notion distinctly and one only, that every part of the sound was a necessary part of the meaning, and that no part of the sound was derived from the union of another sound with it. Thus the whole of a language would consist of vocal sounds, every one of which had its distinct meaning in itself. But spoken language is favourable to the agglutination of sounds, and particularly of those which come into juxtaposition in such a way as to readily unite. Thus, to adopt for the purpose of convenience the names now used, the verb and its pronoun, the word signifying a place or an object, and the word expressing some relation to that place, and other similarly situated words, would respectively form combinations; and thus would arise the phenomenon, which we observe in most languages, of words reducible to various elements, some of which in their simplest form are notional terms, and some which, taken by themselves, convey no meaning at all, but by virtue of their union with the notional term modify and qualify it.

If the language of a nation were committed to writing in a very early state of its progress, it seems probable that the simple elementary forms would be kept much more distinct than in languages which have not been committed to writing except in a more mature form. Thus the mass of the words would be of the monosyllabic class, and the adoption of distinct

symbols for the representation of each sound would seem almost necessary. It must have been in the attempt to represent in writing some of the languages which had been cultivated by longer use, and improved by social and intellectual development, that the discovery of the mode of representing all the sounds of a language by an alphabet originated.

Some languages, as the Greek and the Latin, and, to a considerable extent, the German, express many relations between the various notions contained in any set of words, by means of certain variations in the forms of the words themselves, which variations mainly occur in the terminations of such words. Thus the whole meaning intended to be expressed by the words 'Homo bovem ferit,' may be indicated by any arrangement of these three words. Some languages, of which the English in its present form is an example, have little power of expressing the relation of ideas by any change in the terminations of words; and accordingly they express notions by one set of terms, and relations by another set of words. Such languages are necessarily more limited as to the power of varying the order of their words than languages of the class above referred to.

That part of language which treats of single words and their varieties of form is called Etymology, and is one of the divisions of grammar. Etymology also comprehends the notion of historically tracing the successive forms which the words of a language have had, of separating them into their elementary parts, and then comparing the words, thus reduced to their simplest forms, with the corresponding words and forms in languages known to be related, or in order to establish the relationship, that is, the ultimate identity or unity of words in the languages compared.

That part of language which treats of the arrangement of the words composing a sentence, and of the modifications in form or termination to which such words are subjected in consequence of entering into that combination which constitutes a sentence, is generally called Syntax. As etymology has its general principles, so has syntax; but each language has also its proper syntax.

Within the present century, the study of etymology has been pursued on sound principles and with corresponding success; and the various and apparently capricious sounds of language have been shown to be governed by laws, within limits as strict and invariable as those to which matter in general is subjected. This improvement has been owing in a great measure to the comparison of many languages with each other, instead of confining the field of observation to one or at the most two or three tongues. Nothing has, perhaps, contributed to this improvement more than the study of the Sanscrit, a language which bears so striking a resemblance both in its more important words and in its grammatical forms to the Latin and Greek, the Teutonic and Slavonic languages, as to lead to the conclusion that all must have been derived from a common source. The great similarity of all these languages, and their contrast to the Hebrew, Arabic, and other Semitic tongues, has led to the use of the term 'affinity of languages,' by which is meant that all those languages which employ the same sounds to express the most simple ideas, and adopt the same mode of grammatical inflexion, must originally have been one and the same language, or derived

from some common language. We cannot well suppose that languages which resemble one another in these respects have been derived from any one of those now existing in which these resemblances are obvious: for if we could imagine the Latin to be descended from the Greek, how should we account for the similarity of the Latin and Greek to the Sanscrit and Teutonic tongues? The little intercourse that subsisted between the inhabitants of India and the Western nations precludes the supposition that one nation could have derived its language from the other; and indeed the resemblance is so striking, and descends to such minute particulars, that nothing but a common origin is sufficient to account for their similarity. The error we have been attempting to combat is very general, and nothing is more common than to hear a certain class of etymologists speak of a number of English words as derived from the Latin and Greek, which are in fact the common property of many tongues. Many English words, such as *inspect*, *corporate*, *communicate*, *detriment*, are doubtless derived from the Latin; while others, such as *astronomy*, *geography*, *geology*, have been borrowed directly from the Greek, or manufactured according to settled analogies; but such words as *know*, *lick*, *break*, *yoke*, *sit*, and numerous others, are common to the English, Sanscrit, Latin, Greek, and Slavonic tongues; and it might be said, with as much truth, that the Sanscrit *jñā*, or the Greek *γιν-ω-σκω*, are derived from the English *know*, as that the English word comes from the Latin.

An ingenious writer, a few years ago, put forward some interesting speculations on the various languages in the world. He stated that altogether there are 587 languages and general dialects in Europe, 937 in Asia, 226 in Africa, and 1264 in America, making a total of near 3000. He laid it down as a rule, that in all languages there is one great primary origin. Monosyllables are the primitive sounds, and syllabic compounds the result of interchange with other nations. Hence all the fundamental tongues are monosyllabic as to generic ideas, and compound as to species and varieties. According to his statements, the Chinese, Welsh, Greek, Hebrew, and German, are formed on this principle. The Chinese have 214 radical words and signs to represent these; out of which, by synthesis, other words are formed. He computed that there are 25,000 words in English, 20,000 in Spanish, 25,000 in Latin, 30,000 in French, 45,000 in Italian, 50,000 in Greek, and 80,000 in German. This estimate, however, is open to grave objections.

In the life of Mezzofanti, the great Italian linguist, who is said to have understood seventy-two languages, it is stated that the list of those who have had a knowledge of more than ten languages is a very short one. Mithridates, Pico of Mirandola, Jonadab Alhanse, and Sir William Jones, are stated to have passed the limit of twenty languages; the first two, twenty-two, and the last two, twenty-eight. Müller, Niebuhr, Fulgence, Fresnel, and perhaps Sir John Bowring, are usually set down as knowing twenty languages. For Elihu Burritt and Csoma de Körös their admirers claim eighteen. Renaudot, the controversialist, is said to have known seventeen; Professor Lee, sixteen; and the attainments of the older linguists, as Arias Montanus, Martin del Rio, the

converted Rabbi Libettas Cominetas, and the admirable Crichton, are said to have ranged from fifteen to ten or twelve.

The remarks under the different letters of the alphabet, A, B, C, &c., will show in what manner the forms of words in cognate languages should be compared.

The affinity of languages may be shown by comparing any languages that are related; but the comparison of the languages called Indo-Germanic is the most useful for the purpose. Numerous examples may be found in Bopp's *Vergleichende Grammatik* (Berlin, 1857; and London, 1854); Pott's *Etymologische Forschungen* (2nd edition, 1859); Prichard's *Eastern Origin of the Celtic Nations*, &c. (Oxford, 1831); Grimm's *Teutonic Grammar*; and Winning's *Manual of Comparative Philology*.

The science of language has been most ably pursued in Germany, and also in France. Englishmen were comparatively late in the field. The most recent works on the subject in English are a translation of Diez's *Vergleichende Grammatik der Romanischen Sprachen* (London, Williams and Norgate, 1864); *Philological Essays*, by Garnett (London, 1859); Marsh's *Lectures on the English Language* (New York, 1860); Latham's *Elements of Comparative Philology* (London, 1862); Farrar's *Origin of Language* (London, 1860); and last, though by no means least, Max Müller's *Lectures on the Science of Language* (London, 1861 and 1864.) The researches of the latter gentleman have contributed more, perhaps, than anything else, to popularize the study of the science in Great Britain.

LANGUEDOC, an old province of France, which now forms the departments of AUDE, TARN, HÉRAULT, LOZÈRE, ARDECHE, and GARD, together with the arrondissements of Toulouse and Villefranche in HAUTE-GARONNE, Castel-Sarrasin in TARN-ET-GARONNE, and Puy and Yssengeaux in HAUTE-LOIRE. Under the Romans it formed part of Gallia Narbonensis, and on the decline of their power it had the name of Septimania, from its seven bishoprics—viz., Toulouse, Béziers, Nîmes, Agde, Maguelonne, Lodève, and Uzès. The Emperor Honorius ceded the territory of Languedoc to the Goths, who held it for nearly 200 years, when they were driven out by the Saracens, who in their turn were expelled by Charles Martel. The country thus subjected to the kings of France was governed by feudatory dukes and counts till 1270, when, on the death of the last count of Toulouse, it was united to the crown of France.

The name Languedoc has been transferred to the country from the name given to the language of the inhabitants, who used the word *oc* as an affirmative, and were hence said to speak the *langue d'oc*, as distinguished from the dialect spoken north of the Loire, which expressed the affirmative by *oui*, and was called the *langue d'oui*. The name *Occitania*, sometimes applied to the country, is said to be derived also from *oc*.

The province extended from the Rhône to the Garonne, the most western point reaching the junction of the Tarn with the last-mentioned river. It was bounded N. by Auvergne and Lyonnais, E. by Dauphiné and Provence, S. by Roussillon and the Mediterranean, and W. by Guienne and Gascogne.

It was formerly divided into Haut-Languedoc, Bas-Languedoc, and Cévennes, which had Toulouse, Montpellier, and Alais for their capitals respectively.

LANIADÆ. [SHRIKES.]

LANNES, JEAN, Duke of Montebello and Marshal of France, was born at Lectoure in Guienne, on April 11, 1769. He was born of humble parents, and brought up to the trade of a dyer, which he quitted in 1792 to join a battalion of volunteers raised in the department of Gers, of which he soon became sergeant-major. He rose so rapidly, that at the close of the year 1793 he had attained the rank of chef de brigade. In 1794 he made the acquaintance of Bonaparte, under whom he afterwards served in Italy. After the victories of Montenotte and Millesimo in April, 1796, he was raised to the rank of general, and in 1797 became general of brigade; in which capacity he served till the signing of the treaty of Campo Formio. He afterwards formed part of the expedition to Egypt, where he rose to the rank of a general of division, and maintained his high reputation. He was dangerously wounded at the siege of Acre, and he greatly contributed to the victory gained by the French at Aboukir.

When Bonaparte determined upon leaving Egypt, Lannes returned with him, and rendered him material assistance in the revolution of the 18th Brumaire (November 9), 1799. In the year 1800 he served in the expedition to Italy, and shared the dangers and labour which the French army underwent in crossing the Great St. Bernard. In this campaign he particularly distinguished himself at the battles of Montebello and Marengo.

In 1801 he was sent to Lisbon by the First Consul in the capacity of minister plenipotentiary of France, and he extorted from the feeble Portuguese government every measure that Napoleon required. On his return in 1804, Napoleon, who was now emperor, created him Marshal of the Empire, and afterwards Duke of Montebello. In the Austrian campaign of 1805 Lannes was appointed to the chief command of the left wing of the French army, and in the battle of Austerlitz, December 2, 1805, gave proof of increased skill and judgment.
